For many years Dr. Gubler has been engaged in researches on Muguet. Some time ago he read at the Académie de Médecine a paper on various points of the history of this affection. A few days ago, M. Chatin read a report on this paper at this Academy. He concludes with M. Gubler—1st, that the mouth of persons attacked with muguet is always acid; 2nd, that the acidity of the buccal cavity constantly precedes the development of the *oidium albicans* (the existence of which seems to be constant in muguet); 3rd, that the *oidium albicans* is able to produce the acid fermentation in a solution of sugar.

Professor Trousseau dissents from the reporter concerning the acidity of the mouth. He thinks it is quite wrong to state that the acidity of the mouth leads certainly to muguet. He admits, however, that this is a favourable condition for the production of the disease, but it is not a constant cause. Pregnant women, for instance, have so considerable an acidity in the buccal liquids, that their teeth are attacked by the acids. This is the cause of loss of teeth during pregnancy, but muguet is not a disease peculiar to gestation. Prof. Trousseau also blames the reporter on account of his assertion that muguet is not a grave disease. He cites Valleix, who has found that at the Hospital of the *Enfants trouvés*, of children attacked with muguet, eleven out of twelve died. He adds, however, that in these cases muguet was not the cause of death, and that it was as a prognosis of the approaching death by other diseases that its appearance was grave.

It might be said against Prof. Trousseau that Dr. Gubler and M. Chatin consider muguet as an independent affection, and not as a coincident disease appearing at the last stages of intestinal and other affections. Prof. Trousseau asserts that the mode of treatment proposed by Dr. Gubler (*i. e.* alkalies) has not the value that some other means possess. Carbonate of soda has less power than borax, and borax less than sulphate of copper and nitrate of silver. Besides, hydrochloric acid with honey is a very good remedy;

so that it seems that it is not by its alkalinity that carbonate of soda sometimes cures muguet. Professor Trousseau seems to think that the duration of the disease is more abridged by the application of a solution of nitrate of silver (one part to three parts of water), than by any other remedy.

M. Cazeaux remarks that in private practice muguet has not the grave prognostic value mentioned by M. Trousseau. He has seen but one case of death.

Prof. Moreau says that he has never seen a case of death in his practice in children, and he thinks that the various modes of treatment would be of no avail if the patients were not well fed, while, on the contrary, with good food they may be cured without any treatment.

Al. Blache insists upon the differences between idiopathic and symptomatic muguet. As regards the treatment, he states that certain remedies succeed in one case and not in another, without our being able to explain the success by a chemical or a physical action.

The discussion on the Diseases of the Spine, and on the Consecutive Production of Abscesses, has begun again, after a short interruption, at the Société de Chirurgie. M. Bouvier, who has had a very extensive practice in affections of the spine, affirms that Pott's disease with tuberculous excavations has been cured by many Surgeons. He cites Auran, David, Wenzel, Harrison, Bomfield, and others. He has obtained but one cure. In other cases he has only prevented the disease from progressing. The horizontal decubitus seems to have been the most successful means employed. He thinks that M. Broca and others were wrong in admitting that there are two distinct affections which are confounded under the name of Pott's disease. He tries to show that these two pretended affections are degrees of the same one.

Dr. Brown-Séquard has communicated to the Société de Biologie the results of experiments which show that syncope, as it has been supposed, but never proved, is a favourable condition for the return of life after asphyxia. In dogs it is very rare that, after an immersion of five minutes in water, and consequent deprivation of breathing for the same time, that life may be restored by pulmonary insufflation. Dr. Brown-Séquard has found that when, before drowning dogs, he produces syncope in them by the galvanization of the par vagum, life may frequently be restored by pulmonary insufflation from ten to twelve, or even fifteen minutes after drowning.

## MEDICINE IN SWEDEN.

THE following cases are taken from the Transactions of the Swedish Society of Physicians:—

## CASE OF FRACTURE OF THE SKULL, WITH DEPRESSION.

Communicated by Hr. C. HANJ.

IN the course of last autumn, a labourer on the Skívar estate, about 25 years of age, of strong constitution and healthy appearance, in springing a mine, was struck on the vertex by a piece of granite, and fell senseless to the ground. Some hours after the accident I arrived, and found the patient labouring under a fracture of the skull, in a comatose condition, and unable to swallow. On examining the injury, I discovered in the integuments covering the right parietal bone, a wound some inches long, under which the bone was partly fractured and partly depressed; in the anterior angle of the wound there was a portion of bone one and a quarter inch in length, and three quarters of an inch broad, loose, so that it could be taken away, on which the subjacent dura mater was found torn, and a small portion of the cerebral mass was attached to the bone. The depressed piece of bone was about two and a quarter inches long and one and a half in breadth, it was separated from the surrounding bones, but was so firmly depressed that it could not be moved without the employment of force, on which account I considered it most advisable to leave it undisturbed. Under such circumstances the prognosis, of course, could not be otherwise than highly unfavourable. The patient was bled largely from the arm, a lavement was administered, and ice was applied to the head. After the comatose condition had lasted some days, consciousness began to return at intervals; but the power of vision was very weak in the left eye, and the left arm was

paralysed. Under the continued use of arnica the normal power of vision returned, and the paralysis of the left arm gradually disappeared; the paralysis lingered longest in the fingers of the left hand, which has, however, now for the most part disappeared, so that only an inconsiderable degree of flexion remains. The depressed portion of bone has exfoliated under the continued application of basilicon ointment and the use of the powdered bark, and is becoming more and more covered with granulations. Appetite and sleep have returned, and the patient's strength is, in about four months after the accident, so much restored that he can cut wood, in a word perform tolerably hard work. Neither headache nor any other inconvenient result of the injury remains at the time I write this.

#### CASE IN WHICH THE SYMPTOMS OF BRONCHITIS WERE PRODUCED BY A WOODEN PEG, SUPPOSED TO HAVE BEEN SWALLOWED BY A CHILD.

By Hr. L. BLUME.

On the 16th of October, 1860, Julius Hellstrom, a boy, aged 7½ years, was believed to have accidentally swallowed a wooden peg, of about an inch in length, and the thickness of a quill, which had been used as a cork in a small phial. He was attacked with vomiting, difficulty of breathing, and symptoms of suffocation, which were on the same day, at intervals, very violent, and with an irritative cough.

The little patient complained of a pain in the upper part of the neck, behind the oesophagus. One nostril was most frequently stopped. Blowing the nose produced a disagreeable sensation, and a flapping sound, on which he drew back the air, as if to alter the position of a foreign body. At the end of three days his state continued about the same, and his appearance indicated danger. Attempts to dislodge the foreign body were made with detrusors, forceps, the finger, and by exciting vomiting. Leeches were applied, and the attempts just now described were repeated several times, without the suspected foreign body being removed; the symptoms, however, gradually mitigated. On the third day it was determined to bring the patient to Stockholm, but on the way to Arboga he improved, and by the advice of Dr. Bergman, who considered that the disease was now bronchitis, he was brought home again, where he used several pectoral remedies. The cough continued occasionally troublesome, usually most so at night. The flapping sound already mentioned persisted, until on the 13th of January, 1861, in a violent fit of vomiting, produced by the smoke of burning paper, inhaled in sport, he brought up a peg of the size described, covered with mucus, after which all his symptoms quickly disappeared.

Hence it may be inferred that the peg had been situated behind the soft palate, in the posterior part of the nasal cavity.

Hr. Malmsten reminded the meeting that eight years previously he had brought before the Society the case of an elderly female, who was suffering from valvular disease of the heart, and after an exertion had been suddenly attacked with violent palpitation, which ceased simultaneously with disappearance of the radial pulse in one arm and the occurrence of a violent pain in the hand on the same side. Hr. M. had at that time explained the case by supposing that one of the excrescences on the affected valve had separated, and that, carried along with the stream of blood, it had become fixed in the radial artery. The patient, who recovered on that occasion, had subsequently been repeatedly attacked with violent palpitation and irregular action of the heart, and it had often been observed that, at the same time that the heart became freer, signs of some obstruction to the circulation in the peripheric arteries had manifested themselves, probably in consequence of the existence of similar sanguineous plugs. The pulse, however, always returned after some time in the obstructed artery. The patient had lately been taken ill, after a walk in very stormy weather, when between seventy and eighty years of age, with violent palpitation and dyspnoea, for which she was obliged to take to her bed. Simultaneously with the heart becoming one day quieter, there set in, suddenly and unexpectedly, a violent pain in the right thigh and leg, with cessation of pulsation in the crural artery, soon after which the leg began to swell, and was finally attacked with gangrene, reaching to above the knee. Some days before the patient died she was pulseless also in the

right arm. On post-mortem examination there was found a considerable contraction of the aortic orifice, with a quantity of atheromatous deposit, both on the valve and in the aorta itself. The entire of the right external iliac and femoral arteries were filled with a dense coagulum of blood, above which the vessel was considerably distended. Immediately above the origin of the profunda was a more highly organized clot, adherent to the wall of the vessel. A considerable dissimilarity was observed on examination between this coagulum and the other, which was not adherent. The artery was, as it were, wrinkled. Hr. Malmsten remarked in connexion with this case, that generally speaking but little attention had hitherto been directed to the fact that various diseases arise from the coagulation of the blood during life, both in the venous and in the arterial system. Many cases of senile gangrene, for example, must certainly depend on such a coagulation, arising from a fibrinous excrescence being detached from the heart and conveyed with the current of the circulation until it is arrested in and obstructs a blood-vessel. On the subject of the spontaneous coagulation of venous blood, Hr. Malmsten referred to Bouchut's interesting treatise. In the individual from whom the very beautiful preparation of epithelioma ventriculi exhibited some time before to the Society was taken, a large spontaneously formed coagulum of blood had also been found in the inferior vena cava. The preparation was exhibited.

Hr. Levin observed that the English writer Kirkes, who had published an essay on this subject, was of opinion that many hæmorrhages in the more vascular organs, as the brain, lungs, spleen, and kidneys, must depend upon such a spontaneous coagulation of the blood.

Hr. Malmsten admitted that probably many cases of white softening of the brain proceed from obstruction of the arteries going to the affected parts. The consequences of such a stagnation in the circulation are, as Hr. A. Retzius observed, not always so injurious, because on the one hand the circulation of the blood is carried on through collateral branches, while on the other the coagulated plug is removed by absorption.

Hr. Gråhs had seen several preparations with Mr. Kirkes, which established his views upon this subject.

Hr. Santesson remarked that attention had been drawn to the spontaneous coagulation of the blood under discussion, first in the venous system both in puerperal patients and in those labouring under chronic degenerative diseases (cancer, tuberculosis), where these coagula are met most frequently in some of the larger veins of the extremities, and sometimes within the vena cava. In Utrecht he had seen a preparation exhibiting the lower half of the inferior vena cava completely obliterated, in which case the patient had lived long enough to admit of the establishment of a collateral circulation through the spermatic veins, the vena azygos, and the vena portæ. It was not until afterwards that such coagulations were observed in the arterial system; and there is this difference between their occurrence in the two classes of vessels, that as in the veins the obstruction is formed in the vessel itself, in the arteries it is, in many cases at least, introduced into the latter from the heart. In Bouillaud's work there is a particularly interesting case of this nature, where a patient labouring under endocarditis became quite suddenly pulseless in the left arm up to the axilla. In the smaller arteries, and those which lie nearest the capillary system, the coagulation seems, however, often, and here perhaps most frequently, to depend on a disease in the vessel itself, namely, the atheromatous process. Hr. Santesson had recently had a case of this kind in the hospital. In performing a partial resection of the under jaw, comprehending the portion nearest to the angle on the right side, for a tumour, in a carpenter aged between 60 and 70, the superior thyroid artery was wounded, in detaching the swelling internally, of which a profuse hæmorrhage was the result. In tying the vessel, Hr. Santesson found that its coats were rigid and hard, on which account a second ligature was applied for security. There was no subsequent bleeding. Two or three weeks after gangrene set in quite suddenly in one of the toes of the right foot, and the crural artery on the same side was found, so far as it was accessible to the touch, to have been converted into a solid tube. There was no adventitious sound in the heart. On dissection it was found that the arteries both of the lower and upper extremities were attacked by the atheromatous process. The radial artery of the left arm was completely obliterated for the space of half an inch below the bend of the elbow. It has

often been found that when this disease has localized itself in the peripheric parts, the heart and aorta are freer from it. Such was the case in the present instance, where the morbid deposit did not commence above the situation in which the superior mesenteric artery is given off. Hr. Santesson considered it very probable that this spontaneous coagulation of the blood, which is almost always, at least in the minute arteries, characterized by intense pain, though it is less frequently attended with swelling or any alteration in the temperature of the part, is the cause of a number of diseases now regarded as dissimilar, and bearing different names.

[The foregoing case, with the discussion upon it, forms an interesting contribution to the subject of "Emboli," brought forward about the same time in England by Kirkes, and in Germany by Virchow.]

Hr. Malmsten communicated the following case:—A man, aged between 40 and 50, was admitted some time ago into the Seraphim Hospital, in an extremely emaciated state. He had long suffered from vomiting and inability to eat, so that, according to his statement, he had not for many months, made use of food; he was highly anæmic, and his legs were dropsical. No sign of abdominal effusion could be discovered; there was no tumour in the cardiac region, and the patient had never vomited blood. The diagnosis was, in the most favourable case, chronic gastritis. The treatment was commenced with small doses of blue pill, derivants, and milk diet. At the end of a week the vomiting had ceased, and the man was able to take some food. But his symptoms again became aggravated, and he succumbed. On dissection, a thickening of the pylorus was discovered, proceeding from the muscular coat of the stomach so considerable, that the wall of the latter was here nearly half-an-inch in thickness. On the mucous membrane, which was attenuated, were seen some ecchymoses and viscid mucus. The glands were atrophied. Microscopic examination of the hypertrophied muscular coat showed that the disease was not cancerous, but depended on chronic inflammation, though probably before the application of the microscope to the study of pathology, such an affection would have been looked upon as fibrous cancer of the stomach. Treatment seemed in this case to have produced some diminution of the hypertrophy, for, at the post-mortem examination, the pylorus was open, and the patient had latterly ceased to vomit, and could eat something, which before had been quite impossible. The preparation was exhibited.

Hr. A. Retzius observed, that this preparation showed pathologically, what might likewise be deduced from normal anatomy, that the pyloric portion of the stomach, called by older writers the antrum pylori, constitutes a distinct part of the stomach, distinguishing itself from the remainder of this organ by its peculiar groups of glands and villousities, its strong muscular structure and the folds bounding it, so that this part may be considered as corresponding to the gizzard in birds. A specimen, such as that now exhibited, would probably have been described by the older pathological anatomists as one of alveolar cancer, because on cutting through it, numerous dissepiments are seen, the interstices between which are filled with a semitransparent substance, which, under the microscope, is however seen to be hypertrophied muscular and connective tissue.

Hr. A. Retzius afterwards exhibited a female foetus at full term, sent in by Hr. Hjort, which was destitute of back, neck and throat. The chin was continuous with the greatest convexity of the breast; the occiput with the convexity of the sacrum.

The cavity of the cranium and of the medulla spinalis constituted a large pear-shaped cavity; the squamous portion of the temporal bone was only membranous. The base of this cavity consisted of a plane surface, formed of the basilar part of the occipital bone and the bodies of the vertebræ of the neck, back, and loins. This abnormal state certainly arose from dropsy of the fourth ventricle and medulla spinalis occurring at an early period. The other deformities were only the consequence of this malformation.

Hr. A. Retzius also exhibited a heart with four semilunar valves in the pulmonary artery, sent in by Dr. A. H. Wistrand, and observed that in such pathological specimens, as was here the case, two valves are of the normal size, and the thirds seem to be divided into two.

## GENERAL CORRESPONDENCE.

### MR. SYME'S CASE OF CANCER OF THE TONGUE.

[To the Editor of the Medical Times and Gazette.]

SIR,—As misapprehension may have been occasioned as to the manner in which the pathological department of the Royal Infirmary of Edinburgh is conducted, in consequence of some remarks in a letter published in the last number of your Journal, regarding the late case of extirpation of the tongue, I have to request insertion of the following observations:—

In no Hospital in the kingdom is greater publicity given to the performance of post-mortem examinations than in the Royal Infirmary of Edinburgh; and there was no exception in the present case. The dissection was announced in the usual way, the examination was performed in the presence of all the students and practitioners who chose to attend, and the condition of the diseased parts was publicly demonstrated by me.

With regard to the Pathological Register, I have to state that, according to a regulation of the managers of the Infirmary, no extract with a view to publication can be made from it without the previously obtained consent of the Physician or Surgeon who had had charge of the case; the object of this regulation being to prevent the appropriation by others of what is the literary property of the Medical Officers and Pathologist. In the present instance, one gentleman only (a student) has applied for a copy of the pathological report; but as he had not communicated with the proper authorities in the Hospital, and as he failed to satisfy me as to the grounds on which he made his application, I declined to accede to it, although I offered to give him any verbal information he desired.

I am, &c.

D. R. HALDANE, M.D.

Pathologist, Royal Infirmary.

Edinburgh, 5, Shandwick-pl., Feb. 23, 1868.

### BUTCHER'S SAW.

[To the Editor of the Medical Times and Gazette.]

SIR,—My attention having been directed to an allusion to my name in your Journal of Feb. 13, by an instrument-maker of Glasgow, you will deeply oblige me by inserting the following remarks.

Exception has been taken to my name in connexion with the saw so generally used in excisions, etc., at the present day, and priority of the invention is claimed for another. I shall simply state the facts relative to the first application of the saw which goes by my name, and the circumstances that led to its use. The Profession will then judge as to my claims, both in originality of purpose, and enforcing it upon their notice.

Dr. Forrest and myself were in a distinguished artist's studio in this city, and I happened to take up a wooden bowsaw, that used by artists for cutting out fine work and in curves. I saw Mr. Barker using a similar one cutting ivory, and I repeated the operation to my great satisfaction. I then remarked to Dr. Forrest that it would answer my work well, as I had to amputate the leg next day, and could by its use cut the tibia in a curve, and thus prevent its sharp spine ulcerating through the anterior flap. I shall here insert Dr. Forrest's account of the matter, which he politely sent me to-day.

"MY DEAR BUTCHER,—In reply to your inquiry with reference to your first use of the amputating saw, and what led to its adoption by you, I can, as I preserve a vivid recollection of circumstances in connexion with it, at once meet your request. I had brought you to inspect the works of an artist about whom I was interested, and for whom I had fitted up a studio in my own house, and your observation being given to a saw of the kind you mention which was used by the artist in executing some fine works in ivory, you at once remarked that while it was the same implement on a reduced scale, with which the firewood was cut in pieces, you thought it could still be equitably applied to a further use; and having tried it then and there, you expressed your confidence from the facility it gave you, owing to the narrowness of its blade,

of having the direction of it altered while in use, that it would supply a valuable desideratum to our surgical appliances. I very shortly after had your promise realised to my admiration, by witnessing at your hands the first operation with an instrument of the kind in this city.

"I am, my dear Butcher,

"Yours very faithfully,

"JOHN K. FORREST."

As recorded in Dr. Forrest's letter, I soon tested the capabilities of the instrument, and with great satisfaction, on the living body; and the same wooden saw was used by other Surgeons here, quickly after. I then had a steel one made by Mr. Read of Parliament-street, bearing resemblance to the wooden one in almost every respect. A bar with a screw above was substituted for the cord and piece of wood to make tense the blade, and the blade was made somewhat shallower, and to rotate in its sockets, and a stop added. A full description of the instrument, its proportions, etc., and the cases in which it was at first used, are at length recorded in the *Dublin Quarterly Journal* for August 1851. Moreover, there are directions given for making the saw without the centre bar, and other particulars which have been taken advantage of by others but the source never acknowledged. I shall here insert the woodcut of the instrument which accompanied these remarks, and also the description of its mechanism.

The saw, with its blade reversed for resection.

A, the nut applied to the screw, which makes tense the blade; B B, the pins that secure the blade in the sockets; C C, the handle and nut, by turning which the blade is rotated to any angle; D, the rest, for the index-finger.

In the same paper will be found all the advantages which I conceive this saw possesses over every other, from the peculiarity of its construction. Again, in a later paper on resection of joints, I have figured it with the blade rotated and prepared for that office.

I never claimed priority in inventing the bow-saw; all the older works on Surgery have figured such an instrument, and in the French works of the day such are described; but I do claim the application of the peculiarly shallow blade, the power of rotating it to any angle, and even entirely round, and fixing it so, for special purposes in certain operations; the peculiar setting of the blade, and its pointed extremities, permitting of its being passed behind bones, the direction of the handle in a line with the blade, as original with myself from first to last; as also do I contend for the demonstration of its adaptiveness to all resections and amputations. Years since I figured this saw, described it, illustrated its uses; several times since I have alluded to it, and frequently have others praised its performances, and yet years, I repeat, have passed by, and not until now has my undisputed right been assailed; but I most truthfully assure this Glasgow cutler that I never heard his name before, or that of the Surgeon that he connects with it. Modifications of my saw I know have been made by several, so as to aim at originality; and some of the representations in the English works on Surgery have been copied from instruments constructed with such an intent. The instrument, however, is faithfully copied in Coxeter's catalogue. I have seen myself no reason to depart from the construction of the first instrument, though, as I have already mentioned, I got some made without centre-bar, etc., yet I think the first works best. If made according to the orders which I have laid down and applied according to my directions, I believe the bow-saw to be superior to every other, and claim its adaptation to Surgical purposes as entirely my own.

With a very humble apology for trespassing to so great an extent upon your pages,

I am, &c.

RICH. G. H. BUTCHER.

19, Lower Fitzwilliam-street,  
Dublin, Feb. 16, 1856.

### TREATMENT OF CHOLERA BY EMETICS, WARM WATER, AND ACIDS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having been favoured by my friend Rear-Admiral Trotter, who commanded at that time on the African station, with an important communication on the treatment of cholera as it appeared in the island of Mauritius in the year 1854, I beg to forward it to you for publication.

Mr. Fyler, the author of this singularly successful treatment, is not of the Profession; and it will be seen that he estimates the value of his remedy on the power it possesses of throwing off the choleraic poison. Whether he is right in this common-sense conjecture is comparatively unimportant; but there can be no doubt that the phenomena of the disease materially depend on a prostrate condition of nervous power, and that nothing is better adapted for the removal of this than the act of vomiting, and the means by which it is induced. With the same view of ejecting the poison, Mr. Fyler follows up the action of the emetic by giving immense quantities of hot water; but I would suggest that the exhibition of such large quantities of liquids involves the all-important principle of preventing that inspissated condition of the blood which may be fairly stated as the proximate cause of death, and upon the removal of which all successful treatment is pre-eminently dependent. For, whatever may be the *materies morbi* of the disease, its effects in thickening the blood, suspending the action of the absorbents, and rendering them comparatively insensible to therapeutical agency, is fully illustrated by the inertness of the largest doses of the most powerful medicines on the one hand, whilst on the other, when the treatment has been almost wholly confined to the exhibition of large quantities of water, we have abundant evidence of its efficacy, and simply because of the greater facility with which absorbing power is accomplished, and the blood kept in a state of tenuity sufficient to carry on the purposes of life.

The successful treatment of Mr. Fyler corroborates the impression I have long entertained, that remedies, of whatever kind, to be successful, must be accompanied by large dilutions; that the diluent must be water, and that ablation paralyzes the sentient surface, or suspends the action of the absorbents, and is eminently prejudicial. I do trust therefore that if the Board of Health again favours the Profession with rules for its guidance, water ad libitum may be among its chief instructions. With respect to the efficacy of sulphuric acid, that observant Physician, Dr. Fuller, has already given valuable information, and I may take the liberty of adding to his testimony that of my own experience, not in cholera, but in almost all forms of diarrhoea, for the last thirty years, during which it has been given by me with the most remarkable success, to the nearly total exclusion of all other remedies, except small doses of calomel. I can readily imagine, therefore, its great and salutary influence in restoring the normal condition of the mucous membrane of the alimentary canal after the severe shock it had sustained during the existence of choleraic convulsions.

I am, &c.

RICHARD JONES, F.R.C.S.

Leamington.

[We have read the report referred to by Mr. Jones. It appears unnecessary to publish it, as Mr. Jones's statement that the treatment consisted of an emetic, followed by a large dose of warm water and dilute sulphuric acid, includes the important facts of the report. It is stated that 106 cases were treated, all of whom, without exception, recovered.—Ed.]

THE Fothergillian gold medal for the present year has been awarded by the Council of the Medical Society of London to Dr. Herbert Barker, of Bedford, for his essay on Malaria.

## REPORTS OF SOCIETIES.

## THE PATHOLOGICAL SOCIETY.

TUESDAY, FEBRUARY 16.

Mr. SIMON, Vice-President, in the chair.

(Continued from page 205).

Mr. BRYANT showed a specimen of

## FIBROUS TUMOUR DEVELOPED WITHIN THE LOWER JAW.

S. G., a healthy-looking boy, aged 9, was admitted into Guy's Hospital under the care of Mr. Cock, on Jan. 20, 1858. Two years previously he had received a blow upon the left side of his chin. The accident was followed by pain and tenderness when the part was touched, but by no swelling. Six months after the accident a tumour appeared over the spot, and this has since gradually increased. The tumour was unattended with pain, except when roughly manipulated. On January 23, Mr. Cock excised the growth, and found it emerging from the bone, but embedded in it. The bone over it had become absorbed, as there was no osseous shell, and the margins of the cavity were slightly raised and seemed bevelled off. Upon its removal the dental nerve was seen divided and lying low in its bony canal. The tumour during its excision was divided into two parts; it was about the size of a walnut, and firm to the touch; the dental nerve passed through the centre of the projecting portion, and could easily be dissected off; at the aperture its sheath seemed to be adherent to the growth. The small portion which was embedded in the bone was without nerve, but it had a passage through its centre, where the nerve had evidently passed, but which during the operation had been pulled out, and left hanging in the wound. Microscopically the tumour was seen to have been composed of delicate fibre tissue; it had evidently been developed in the dental cavity, and surrounded the nerve, absorbing the bone during its growth. The absence of pain is worthy of note, as from the relative position of the tumour and the nerve, together with the fact of its development in bone, severe pain might have been expected.

Dr. MARKHAM brought forward a specimen of

## SIMPLE HYPERTROPHY OF THE HEART, WITHOUT DILATATION OR VALVULAR DISEASE.

The man from whom it was taken died suddenly from apoplexy. The heart weighed 24 ounces; its muscular tissue was firm and healthy; the valves all competent. A large clot of blood was found in the brain. All other organs of the body were in perfect health, with the exception of the arteries. The cerebral vessels were all atheromatous, and so also was the aorta, but not in an advanced degree. Dr. Markham remarked that the condition of the cerebral vessels was probably the condition of the smaller arteries in all parts of the body, and that the obstruction which they must have caused to the circulation of the blood was the cause of the hypertrophy. Cases of hypertrophy of the heart are occasionally met with where no causes for the hypertrophy are found, and in these cases different hypothetical explanations of the hypertrophy have been given. In such cases, it is possible that a similar state of the smaller arteries would have been found had it been sought for. This case also shows that the state of the aorta is no index of the extent of the atheromatous degeneration in the smaller vessels.

Dr. MARKHAM also showed

## A HEART,

in which there was a distinct "bruise," as large as a crown-piece, on the inner surface of the septum in the left ventricle. The heart was taken from a man who fell from an omnibus, and in falling first struck his side, and then the back of his head. He died from effusion of blood over the brain. The bruise was, doubtless, caused by the violence of the blow on the thorax.

Dr. GIBB exhibited specimens of

## CIRRHOSIS OF THE LIVER WITH BILIARY CALCULI,

which he had taken from the body of a man 73 years of age, who had been long given to intemperance, but died appa-

rently from old age. The lungs were healthy, but some old pleuritic adhesions were present; the heart was enlarged, together with its large vessels, and its valves were studded with atheromatous deposits; both coronary arteries were also affected with atheroma. The liver was small, hard, and nodulated, in a state of cirrhosis of the hobnailed variety; the gall-bladder was almost completely imbedded in its surface and filled with four calculi. Three of these were uniform in size and colour, while the fourth, the size of a robin's egg, was white, and consisted of pure cholesterine. The surface of this calculus was crystalline, and this was due to an aggregation of flat and foliaceous crystals of cholesterine, as seen under the microscope, strongly resembling the well-known mineral selenite, or crystallised sulphate of lime. This calculus blocked up the cystic duct, and had become encysted, the gall-bladder being quite empty of bile. The spleen was enlarged, and covered with irregular hard white patches of a cartilaginous consistence, in size from a crown piece to a pea. One of the interesting features of this case was the presence of a distinct cyst around this oval calculus, which no doubt was the reason of its possessing such a beautifully crystalline surface.

Dr. GIBB also exhibited two specimens of

## INSPISSATED BILIARY CALCULI

removed from old women. One of them had died of old age, and nothing unusual was found, excepting two fibrous tumours growing from the walls of the uterus, the size of a walnut and a marble respectively. Both of these calculi had now crumbled into pieces, were of a blackish-brown colour, and weighed ten and seventeen grains.

## MULBERRY RENAL CALCULI FROM THE HORSE.

These were three most perfect specimens, shown to the Society by Dr. GIBB, taken from the kidney of three different horses dying of chronic disease: thus one died of pulmonary phthisis, another of abscess in the liver, and a third from renal abscess associated with pyelitis. All three had been pining away for some time before death. The weight of each was considerable, and all were composed of oxalate of lime. They were covered with minute crystals of the same substance, visible to the naked eye, and as they possessed a brown colour, they resembled in a striking degree fine crystals of ferruginous quarts. Dr. Gibb had reason to believe that the presence of crystals on the surface of calculi is rare, although they are described by Dr. Golding Bird and Dr. Owen Rees, and of those which do occur they are almost invariably the octahedral forms, both opaque and transparent, of the oxalate of lime.

## WESTERN MEDICAL AND SURGICAL SOCIETY.

FEBRUARY 5, 1858.

Dr. FULLER, Vice-President, in the Chair.

Dr. WM. OGLE read a paper

## ON THE REGISTRATION OF SICKNESS.

The paper was introductory to the subject rather than on the subject itself. In the course of his remarks, Dr. Ogle observed that though a comparatively few would be engaged in the special work of registering disease, the work must be in reality a combined work of the Profession, and viewed in this light it is a subject worthy of notice. Bearing in mind that we are members of one body, it must be that there are certain duties which cannot be performed by separate members without the simultaneous action of the whole body. But assuming that the body of the Profession will be willing to co-operate, there is still the special duty to be performed, and this duty is a more onerous one than appears at first sight. Uniformity is a final necessity, and inasmuch as many men have many minds, it seems almost essential that the record of the registrar should be a record of his own personal observations. The difficulty of allowing a medical man to collect his facts respecting a patient under the care of another may seem insuperable; but difficulties in a good cause are simply to be overcome; and when the duties of the registrar are more fully understood, and the necessity of such an officer for the public

advantage is more clearly seen even than at present, difficulties will be met with determination, and, like most imaginary difficulties, will vanish. It will be found that this second person will have no time to do his own work and that of another man, the family medical attendant. His province will be to assist; in his absence there is much for which the family medical attendant can find no time; for instance, the cognate sciences of chemistry and pathology cannot be systematically applied, (and without them registration is little worth,) so long as they are left to the leisure and inclination of separate individuals. It would be compatible with the duties of the young physician to perform such work, and provided that his mind was not directed to the acquirement of a livelihood by engaging in general practice, his education would point him out as specially fitted for the service. The payment for these services is no doubt a difficult subject. At present it is more easy to say who should not than who should pay. Dr. Ogle gave reasons against payment by the State and against payment by a compulsory local rate, and argued, that if, after all, the young physician did the work for nothing he would be doing good service without injury to any one, and it could not be urged against him as at present that his gratuitous work was to the prejudice of his Professional brethren. Dr. Ogle referred briefly to the attention that was being given by the public to Medical science, and hoped the day was not far distant when combined effort on the part of the Profession, in answer to more liberal and enlightened views of the public, would bring about an efficient system of registration of disease and other advantages which cannot be secured by Act of Parliament.

#### OIL IN THE RIGHT PLEURAL CAVITY.

Mr. HATFIELD then narrated the particulars of the post-mortem examination of a case of sudden death in which oil was found in the right pleural cavity. The autopsy, twenty-seven hours after death, discovered the body and all the various internal organs far advanced in decomposition. The latter, however, were all healthy, with the exception of the right lung, which was highly congested and adherent throughout to the pleura costalis, and the heart, which was pale and the walls attenuated. The oil gushed out upon making the first incision into the thoracic cavity. Some of it was collected in a phial, when it rapidly solidified. The serous surface of the intestines was also saturated with oil.

### PARLIAMENTARY INTELLIGENCE.

#### HOUSE OF COMMONS.

##### MEDICAL DEPARTMENT OF THE ARMY.

Mr. GREGAN asked when the warrant in reference to the Medical Department of the Army, in accordance with the recommendations of the Committee, would be issued.

Sir J. RAMSDEN said that the subject was at present under the consideration of the Government; but the recommendations referred to were so numerous and important that they would require very great deliberation before they could be finally adopted. It was impossible, therefore, to state any precise time when the warrant would be issued.

##### PETITION.

A petition was presented by Mr. H. A. Bruce, from guardians of Merthyr Tydvil, for introduction into the Lunatic Asylum Act of a clause authorising a committee of Guardians of each union to visit such asylum, and empowering them to discharge their own lunatics at their discretion.

### MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on February 18, 1868:—

BARNES, GEORGE, Milton Pewsey, Wilts.

LEWIS, HENRY

MANT, NEWTON, Wirksworth, Derbyshire.

MASON, BENJAMIN EARNSHAW, Calcutta.

PEMBERTON, CLARENCE LINDEN HENDERSON, Southsea.

#### DEATHS.

**CHATTERLEY.**—At Port Adelaide, suddenly, William M. F. Chatterley, M.R.C.S.E. Late of Hereford-square, Brompton.

**CLULEY.**—Feb. 17, aged 49, William Cluley, M.R.C.S. Eng. 1831; L.S.A. 1830. Ashton-under-Linc.

**COOKE.**—On the 11th inst., Mr. C. J. Cooke, M.R.C.S. Eng. 1840; L.S.A. 1839. Clay-next-the-Sea, Norfolk.

**DALTON.**—On the 12th inst., in Mecklenburgh-square, Joseph Dalton, M.R.C.S. Eng. 1818; L.S.A. 1817. Late of Doughty-street.

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY.**—The Annual General Meeting of the Royal Medical and Chirurgical Society, for the Election of Officers and other Members of the Council for the ensuing year, to receive the Auditor's Report, the Report of the Council, etc., will be held at the Society's House, 53, Berners-street, on Monday next, at 8 o'clock precisely. We append the list of officers proposed:—**President**—Sir Charles Locock, Bart. M.D. **Vice-Presidents**—\*James Arthur Wilson, M.D.; \*Alexander John Sutherland, M.D. F.R.S.; \*Charles Hawkins; James Dixon. **Treasurers**—George Cursham, M.D.; \*Alexander Shaw. **Secretaries**—Andrew Whyte Barclay, M.D.; Spencer Smith. **Librarians**—William Wegg, M.D.; \*Charles Hewitt Moore. **Other Members of Council**—\*George Burrows, M.D. F.R.S.; \*Charles Hutton, M.D.; \*Thomas William Jones, M.D.; \*Joseph Ridge, M.D.; John Snow, M.D.; \*Henry Thomas Chapman; \*William White Cooper; \*John Fosse Harding; \*William Augustus Hillman; \*James Luke, F.R.S.—Those gentlemen to whose names an asterisk is prefixed were not on the Council last year.

**MEDICAL LIFE IN INDIA.**—The following is an extract from a letter from an Assistant Surgeon in the Company's service, dated Cawnpore, December 14:—"During the six days we were in the intrenchments I had tremendous work; all the wounded in the two previous battles outside were brought in. The first day I amputated eight limbs, dressed more than eighty wounded men, scarcely knowing night from day, eating beef and biscuit and drinking tea and water whenever I could get a chance. Three round shot passed through my hospital roof, bringing down plenty of tiles and dirt, but injuring no one. The bullocks and camels suffered most, several being killed. Bullets continually pattered against my hospital walls, but all high up, as the earthworks protected the lower part. The hospital has been again removed to what was formerly the Dragoon barracks, nearer the intrenchments than the place I told you of last; we have now 800 sick and wounded, with only one surgeon, dressers, and eight assistant surgeons. The work I have done lately no man would believe; during the time we were in the fort six days were but as one of incessant toil; it had one good effect, that I cared but little what the enemy did, though towards the end I was nearly done up. Jaffer's (his man-servant) expression was, 'Sir, the work has dried you up; if Mem Sahib saw you, she would indeed cry.' However, thank God, I am all right again. All my clothes are spoilt with blood. I went about in my shirt-sleeves, bareheaded; my hair was matted with blood; my arms and hands covered. Blood spirted from arteries into my mouth and eyes; I was indeed all blood. How many bullets I extracted, how many wounds I probed and stanchd and dressed, how many operations I performed or assisted at, I cannot say; but, certainly, one thing is true, that in one week I saw more surgery than most surgeons see in a lifetime, and I trust I have improved myself."

**THE LATE DR. ROLPH, OF PORTSMOUTH.**—It is hardly three months since we commented on an inquest held on a woman attended by Dr. Rolph, and exposed the injustice of the verdict. The deceased gentleman, according to a correspondent, "had practised his profession in Portsmouth, with honour to himself and unbounded usefulness to a large circle of patients, during a period of fourteen years. He was a gentleman of high professional and literary attainments, and much beloved and esteemed by all who knew him." But his persecutors, not content with the odium they had thrown upon him, made a subscription, and "inserted in the Port-

mouth papers an advertisement to the effect, that the 'Committee of Subscribers' had erected to the memory of Mary Berry a tombstone, with a suitable inscription. This 'suitable inscription' was a copy of the verdict of the Jury, viz. 'The Jury find that Mary Berry died of child-bed fever, but they express their condemnation of Dr. Rolph's treatment and conduct, as they consider him chargeable with great neglect during child-birth!!!' Dr. Rolph was induced to visit the churchyard and inspect the tombstone. He returned home, after having paid some few professional visits, and shortly after his arrival expressed to Mrs. Rolph, 'I am extremely ill; my heart is broken; my brains appear to be on fire; I never can live to bear up against such fiendish torture.' He then talked occasionally for two or three hours, after which his intellect became confused; he talked incoherently, and at half-past nine o'clock on Wednesday morning he expired, a victim of the most cruel persecution. Mr. Wiblin, of Southampton, and Mr. Garrington, J.P., were in attendance upon the deceased gentleman during his short illness."

**ACTION ON THE SALE OF A PRACTICE.**—The case *Lovegrove v. Matthews* was tried in the Court of Exchequer last week. Both the parties are Surgeons, the plaintiff suing the defendant on his bond for £500, given on the purchase of his business at Horsham for £900, of which £400 was paid down at the date of the agreement, and the residue secured by the bond of the defendant and his father-in-law, payable at the end of a year. The defence was that the plaintiff had fraudulently misrepresented the business to be worth £900 a-year, whereas it was of far less value, as testified by the business done during the six months after the agreement, at which time the defendant proposed to rescind the bargain. The Chief Baron, however, expressed it to be his opinion that, inasmuch as the defendant could not reinstate the plaintiff *in statu quo*, he having succeeded to certain appointments and having enjoyed the business, such as it was, according to his statement for six months, the alleged misrepresentation afforded no answer to this action. The remedy of the defendant was by a cross action, but on the bond he was liable. After much discussion, the learned Judge directed a verdict for the plaintiff for £528 2s. 6d., principal and interest.—**MATTHEWS v. LOVEGROVE.**—This case was the cross action alluded to by the Chief Baron in the last. The cause resolved itself into the question whether the defendant, when he represented that his business had produced on an average of the last five years a gross receipt of £600, had made a true or false representation; and, as that question could only be solved by the laborious process of dissecting his books, it was agreed on all hands that the case was a proper one to be "inquired into elsewhere." The cause was accordingly referred to Mr. Dasent.

**ROYAL LONDON OPHTHALMIC HOSPITAL.**—The annual meeting of the governors of this noble charity was held at the Hospital on the 23rd February last, Mr. Labouchere the Treasurer and Vice-President in the chair. A tribute of respect was paid to the memory of their late President the Earl Fitzwilliam. William Cotton, Esq., D.C.L., was chosen as the new President. The Bishop of London, Sir Charles Rugeley Price, Bart., J. G. Barclay, G. H. Barnett, and G. H. Foster, Esq., were chosen Vice-Presidents. The Report stated that 12,577 patients had been admitted during the past year, and that such was the pressure upon the Committee for more wards for in-patients, that they intend, when the funds will permit, to build a new wing in addition to the extensive accommodation for out-patients already recently effected. It appears, notwithstanding the increase of its supporters, that the expenditure had exceeded the income nearly £1200. Thanks were voted to the Medical Staff, and to several gentlemen who had made valuable contributions to the library. The usual resolutions having been agreed to, the meeting separated.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, February 20, 1858.

### BIRTHS.

Births of Boys, 1031; Girls, 942; Total, 1963.

Average of 10 corresponding weeks, 1843-57, 1903.

- The Nature of Inflammation, and the Principles on which it should be treated. By Thomas Inman, M.D. Liverpool: 1858.
- A Treatise on the Employment of the Speculum in the Diagnosis and Treatment of Uterine Diseases. By Robert Lee, M.D., F.R.S. London: 1858.

## TO CORRESPONDENTS.

DR. CONOLLY'S Fourth Paper will appear next week, with a Photographic Portrait as usual, and two Woodcuts.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have been excessively amused to read in your Notices to Correspondents of the 20th ult., lines "borrowed" from the Edinburgh Medical Journal, and I fancy the author of the lines so "borrowed," is as much

amused as I am to learn that he contributed them to your celebrated contemporary. Surely the editor of the northern light—which professes to lighten all our darkness—where his light falls, has not ventured to give them as "original." Pray enlighten your readers who do not read the "Edinburgh," upon this point. Every one will recognise the lines in question as "borrowed" from your own paper, who like me is

A CONSTANT READER.

[OUR MONTHLY CONTEMPORARY certainly had not the grace to acknowledge the source of his inspiration.—Ed.]

#### CHLORODYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In justice I beg you to insert these few lines in reply to Dr. Medlock on the analysis of chlorodyne, as published in your Journal of last week, the 20th inst.

I do so that the Profession may not be misled by so erroneous a statement, or overlook the evasive manner in which his analysis is dictated, "inasmuch" as his observations foreshadow certain constituents, reserving this most extraordinary condition to his analysis, that it is what he states, or something else.

I beg to assure your readers in all truth and sincerity, that Dr. Medlock's statement is untrue, and that it is the something else which his chemistry cannot detect, and moreover that it is what I have ever stated to the Profession to be, an alkaloid, which to my knowledge has never been used in medicine prior to the introduction of Chlorodyne. I have never disguised from the Profession that this alkaloid is compounded with other organic products, and for the expressed object of preventing detection, and misleading the analyser. Several analyses of Chlorodyne have appeared, each entirely differing from the other. In this case I am quite sure the good sense of the Profession will receive with considerable distrust a statement, arising as it does from the Assistant to a rival establishment of recent origin; if otherwise, it will only be necessary to prepare the compound suggested, to confirm how essentially it differs in its therapeutic action and physical appearance from Chlorodyne as introduced by Dr. J. Collis Brown, which is acknowledged throughout the Profession to differ entirely in its action from any Medicine ever used in this country. I leave the subject in the hands of the Profession to say how far it is justifiable on the part of any one to publish erroneous statements in so important a matter as where life is concerned.

I am, etc.

J. T. DAVENPORT.

Feb. 22, 1858, 33, Great Russell-street, Bloomsbury.

#### THE COLLEGE MUSEUM ASSISTANT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Though I am one of the rejected candidates for the appointment of Assistant in the Museum of the College of Surgeons, I should not have troubled you or the Profession on the subject, had it not been broached in your number of this day by Mr. George W. Lawrence. As it has been started, I will ask for space in your Journal to say a few words on the matter. Having devoted a very long period to the study of my Profession, having been engaged as House-Surgeon and as Assistant-Surgeon in several Hospitals, and having for years past devoted great attention to morbid anatomy in the dead-house and by the systematic examination of specimens in Museums, many of my professional friends considered that my qualifications rendered me very suitable for the office.

I was myself ignorant enough to suppose that holding the diploma of Fellowship of the College, I should be considered by the gentlemen in whom was vested the recommendation of a candidate to the Council of the College to have a prior claim, *ceteris paribus*, to any person not holding the same diploma. But although there is a tolerably searching preliminary examination in classics, mathematics, etc., and after that a professional examination lasting three days, and including dissections of the dead body, it does not appear that when obtained the testimonial is of much utility; and lest any one should hereafter think that it would avail him in the event of his applying for an appointment at the establishment in Lincoln's-in-fields, I desire to place my own case on record. Mr. George W. Lawrence complains of not having received official information; yet, judging from what he states, he is in possession of the opinions of the members of the Museum Committee to a much greater extent than has been vouchsafed to me.

With apologies for troubling you,

I am, &c.

JAMES J. RUDALL, F.R.C.S. (by exam.)

Rochester-square, Camden-town, Feb. 20.

*Students*.—See a paragraph on the subject in our leading columns.

*erratum*.—The important omission of the word NOT completely altered the sense of an answer to Mr. Brentwood last week. It should have read, "It is not usual for gentlemen who have passed the first M.B. examination of the University of London to use the letters M.B. after their names." It is neither usual nor right to do so.

Dr. Hamilton Roe's paper on Flourel Effusion shall appear in an early number.

Dr. Sylvester.—The letter shall appear next week, if possible.

Assistant might find his friend's address by writing to the office of the Army Medical Department.

F.T.H. can only obtain the information he requires from works on each Colony.

A Liverpool Correspondent.—The account given by John Corrin of the death of his wife, if correct, is calculated to throw great discredit on the Surgeons implicated, but we trust they will be able to offer some explanation of their conduct.

Dr. C.—We do not obtain a very clear idea of the case from the report sent, but it is evident that if a Medical man find the visits of a clergyman injurious to a patient he should not allow them to be continued without remonstrance.

Mr. Shillitoe's letter on the treatment of Boils shall appear next week.

Dr. Taylor.—Many thanks. The comments were most unfair.

Mr. Field's paper shall appear as soon as possible.

A Friend (Maldstone).—It was quite unnecessary to notice the remarks. The son's diploma does not make the father a qualified practitioner.

*Inquirer*.—The receipts of the Commissioners of Lunacy during 1857 were £14,137, of which £12,971 were expended for the purposes of the commission. The salaries of the Commissioners amount to £2970, and of the Secretary to £800 per annum.

#### COMMUNICATIONS have been received from—

Dr. ANDREW SMITH; Dr. CONOLLY; Mr. CESAR HAWKINS; Dr. G. JOHNSON; Dr. MARCET; Dr. ROBERT LEE; Mr. WHARTON JONES; Dr. PRINCE, Edinburgh; Dr. HALDANE; Dr. GRAILY HEWITT; Dr. IMMAN, Liverpool; Mr. H. SMITH; Mr. J. Z. LAURENCE; Mr. W. MARTIN; Mr. BROWNFIELD; Mr. F. HOLMAN; Mr. LEAK; Dr. WHITE; Mr. GODFREY; Mr. J. WILSON; Mr. R. TIFPEN; Mr. T. E. LANDER; Mr. J. BARROW; Mr. T. BLATHERWICK; Mr. IRVINE; Mr. WARWICK; Mr. R. TOMKINS; Mr. R. BRADSHAW; Dr. GRAY; Mr. FARR; Mr. J. PATTERSON; Mr. STRETTON; M.A.; Dr. HAMILTON ROE; REGISTRAR GENERAL; Dr. HALLFORD; Dr. BROWN-SQUARD; SECRETARY GENERAL, BOARD OF HEALTH; Mr. BARLOW; Mr. McDERMOTT; Mr. WHEATSTONE; Dr. ALLEN; Mr. SANSON; Dr. SYLVESTER; Mr. BAINBRIDGE; Mr. CORNISH; Mr. ADAMS; Mr. JONES; Mr. SHILLITOE; Dr. TAYLOR; Mr. FIELD, Brighton; Mr. GORDENIER; Dr. CROCKEN; Mr. VALE; Dr. McWILLIAM.

## APPOINTMENTS FOR THE WEEK.

### Feb. 27. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8 p.m.: Anniversary.  
ROYAL INSTITUTION, 3 p.m.: Professor Bloxam, "On the Chemistry of the Elements which circulate in Nature."  
MEDICAL SOCIETY, 8 p.m.: Dr. Rogers, "On some of the inflammatory and obstructive Diseases of the Cæcum, with remarks on the use of Violent Purgatives."

### March 1. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopædic Hospital, 3 p.m.  
ROYAL INSTITUTION, 2 p.m.: General Monthly Meeting.  
EPIDEMIOLOGICAL SOCIETY, 8 p.m.: Dr. Richardson, "On the Investigation of Epidemic Diseases by Experiment."  
ENTOMOLOGICAL SOCIETY, 8 p.m.

### 2. Tuesday.

Operations at Gny's, 1 p.m. Westminster, 2 p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Biology."  
PATHOLOGICAL SOCIETY, 8 p.m.

### 3. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Orthopædic Hospital, 3 p.m.  
ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Croonian Lectures—Dr. Sutherland: "The Pathology, the Morbid Anatomy, and the Treatment of Insanity."  
PHARMACEUTICAL SOCIETY, 8 p.m.

### 4. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL SOCIETY, 8½ p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."  
MEDICAL SOCIETY OF UNIVERSITY COLLEGE, 8 p.m.: Mr. Balmanno Squire: "Volcanos, Earthquakes, Hot Springs, etc., their causes and mode of action."  
HARVEIAN SOCIETY: Haity Lobb, Esq., "On Galvanism as a Therapeutic Agent."  
MEDICAL SOCIETY OF KING'S COLLEGE: Dr. H. Hyde Salter, V.P., "On Asthma."  
GROSVENOR PLACE SCHOOL MEDICAL SOCIETY, 7½ p.m.: General Meeting.  
LINNEAN SOCIETY, 8 p.m.  
CHEMICAL SOCIETY, 8 p.m.

### 5. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.  
ROYAL INSTITUTION, 8½ p.m.; Professor C. Piazzi Smyth: "Account of the Astronomical Experiments on the Peak of Tenerife in 1836, illustrated by Photographs."  
ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Croonian Lectures—Dr. Sutherland: "The Pathology, the Morbid Anatomy, and the Treatment of Insanity."  
WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m.: Mr. Martyn, "On Cases of Disease of the Oesophagus, one involving the operation of Tracheotomy."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations are expected at this Hospital to-day (Saturday) at 2 o'clock:—  
Amputation of foot (Perigord); removal of bursa patellæ; removal of growth from head; division of ham-string tendons; by Mr. Fergusson.  
Ligature of common carotid artery; by Mr. Bowman.

## ORIGINAL LECTURES.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

## LECTURE II.

IN Dr. Gull's (a) valuable contribution contained in the *Medico-Chirurgical Transactions*, we find a case in which there was tenderness over the mastoid process and down the neck, behind the ramus of the jaw, on the right side, with deafness on the same side; but the external auditory canal and the surface of the membrana tympani appeared to be free from disease. The patient stated that four years ago, when working in a coal-mine in Staffordshire, he had received a blow on the right side of the head, which was followed by deafness and discharge from the ear. At the time of his admission into Guy's Hospital, the prominent symptoms, which were reported to have existed about a week, after exposure to cold, were those of irritative fever, with severe rigors and pains in the head. In the course of three or four days came symptoms of pleurisy, and then of lobular pneumonia, with perforation of the pleura-pulmonalis, and the patient died in nine days. The right lateral sinus, at its commencement in the torcular Herophili, contained an adherent clot; further on in its course, the contents of this sinus were fibrin, partly softened into a greyish puriform fluid and pus. The internal jugular vein was filled with the same at the upper part, and obstructed by an adherent clot, as far down as its junction with the subclavian. Over the petrous portion of the temporal bone, and continuous with the descending portion of the lateral sinus, the dura-mater was sloughy. Pus lay between it and the bone, and was infiltrated along the coats, and into the sheath of the jugular vein. The external auditory canal was healthy; the membrana tympani intact, and the malleus *in situ* upon it; but the other portions of the chain of bones were loosened from their connexions. The lining membrane of the tympanum was thickened and vascular. There was caries of the posterior and superior wall of the tympanum, and of the adjacent mastoid cells, extending to the dura-mater at two points; in one, as this membrane lies upon the superior part of the petrous bone, and in the other, as it covers the floor of the lateral sinus. There was no change in texture of the brain substance, which was quite healthy, excepting a slight discolouration of the cerebellum in contact with the diseased dura-mater. There was extensive pleurisy, with lobular pneumonia on the right side, and perforation of the lung in two places. The left lung was universally affected with acute recent pneumonia, and a small amount of plastic exudation existed on the pleura. The other organs presented nothing remarkable.

There is, I think, but very little doubt that the disease, in this case, originated in the accident. The history and the appearances observed about the ossicula of the ear certainly tend to show that the blow on the head was a very severe one, and gave rise to disease in the petrous bone, which went on smouldering for years, and ultimately led to the inflammation of the sinus, and jugular vein, and thence to the secondary affections noticed in the chest.

In the three cases which I have just brought before your notice, we can trace, in its various stages and consequences, inflammation of the lateral sinus dependant upon an injury done to the bone. In the first, we find the sinus simply blocked up by fibrinous deposit; in the second, there is extensive suppuration of this sinus; and in the third, not only is there suppuration of this sinus, but there are also inflammation and suppuration spreading to the jugular vein, with a secondary affection of the lungs and pleurae.

And this leads me to refer once more to secondary deposits in connexion with injuries of the head. This I shall, however, do but very briefly, as I have already fully examined the subject when I spoke of scalp wounds and contusions of the bones. By some it may perhaps have been thought that it would have been better had I kept altogether this subject of purulent infection until after I had fully considered all the various injuries of head. Being anxious, however, to trace out uninterruptedly the numerous evils which might arise from a scalp wound or a contusion of the bone, purulent infection naturally fell in as one of the greatest evils of these accidents in hospital practice. And then again I was led to follow the plan which I did, having much more frequently met with purulent infection in connexion with these accidents, than with fractures or other injuries of the head.

Thus in twenty-three cases of simple scalp wound, or contusion of the bone, which ended fatally at St. George's Hospital within the space of ten years, purulent infection was noticed in fourteen instances; whereas, in seventy-eight cases of fracture terminating fatally within the same period, it was noticed in six cases only, and even of these, five were compound fractures. Such a statement as this may, at first sight, appear strange; but it is explained by the fact that, in far the greater number of fractures, the patient died long before the period at which purulent infection usually sets in. In the vast majority of these cases, it was an extensive extravasation of blood, or some serious lesion of the brain, which led to the death of the patient, and there was no suppuration either about the fracture, or other parts of the cranial region.

Purulent infection deserves, then, to be especially and most prominently noticed in connexion with the simpler forms of injuries of the head, that is, with scalp wounds and contusion of the bones.

I do not think it necessary to tabulate these six cases of purulent infection which occurred in connexion with fractures. These cases simply point out the same broad facts. The lungs were more or less affected in all the six cases; the liver once only; and in three cases the hip-joint contained large quantities of matter.

In speaking of operative interference, you will have observed that I have not, as yet, said a word about the fact that fractures with depression are not attended with so much danger in the child as in the adult. The well-known fact that a depressed piece of bone may be allowed to remain in a child without producing the serious results commonly noticed in an adult, must, however, be taken fairly into consideration whenever we have to deal with such injuries in children. In children, let us ever bear in mind that we may safely leave much more to nature, and consequently that we may, in a child, postpone the elevation or removal of the broken bone, which in an adult we should proceed to operate upon at once.

Again, in speaking of operative interference in fractures with depression, you will also, doubtless, have observed that I have not yet distinctly mentioned the different modes of proceeding in such cases. In operating for a fracture with depression, we must recollect that our only object is to elevate or remove the fragments which are driven down. Now, if the form of the fracture is such as to admit of our doing this solely by means of the elevator, so much the better; and most carefully ought we to examine every fracture with depression, to see if we cannot, by any possibility, get the bone up by means of the elevator before we resort to any other operation. If the elevator cannot be thus used, our next duty is to see if the fracture is such as to allow of our gaining sufficient room by the removal of a narrow piece of the sound bone overhanging the depressed fragment. This mode of operating, so strongly recommended by Hey of Leeds, is much more practised in this country than on the Continent; in fact, so much so that Hey's saw, as it is commonly called, is always used by English Surgeons in preference to the trephine when the case is a suitable one. The use of the trephine, as far as depressed bone is concerned, is then, in the present day, restricted to those cases in which the edge of the fracture is regular, and without corners. And in using this instrument it behoves us to remove as little bone as we possibly can with due safety to our patient; but, on the other hand, let us bear in mind that in being over-cautious as to the removal of bone, we may leave a piece of the inner plate driven down, and sticking into the brain, and thus lose the good which might have arisen from the operation, had it been

(a) Vol. xxxviii. p. 138.

well performed. In looking over the skulls in our different museums, it is curious and most instructive to observe how frequently a sharp edge of the inner plate of the bone has been left depressed. Such a fact as this ought certainly to teach us most carefully to examine the state of the inner plate at the margins of the trephine-hole; and, if need be, to proceed at once to apply another crown of the trephine; for, assuredly, if we operate at all, it would be better to run the risk of removing too much, than to leave a piece of bone driven down, and injuring the dura-mater.

After the removal of parts of the skull, it was the custom in former times to protect, by plates of silver or lead, or by some other means, the portion of brain thus left exposed. Of late years, however, this practice has been abandoned; and now the only protection one usually sees is that afforded by the thickened dura-mater and integuments, as it happens but very rarely that ossification takes place sufficiently to fill up the gap. It stands to reason that where the brain is thus exposed, there must always be some risk of its being injured; still we may not unfrequently meet with patients who, under such circumstances, have gone on unharmed for years and years. Now and then it happens that matters do not go on so prosperously. You will all doubtless recollect the oft-quoted case of the poor girl, who lost her life by the giving way of such a cicatrix during a violent fit of coughing: hernia cerebri followed; then paralysis of the limbs, and death within five days after the occurrence.

And this reminds me of a case which I saw some years back. It was that of a man who had adopted a singular mode of making good a deficiency in the bones of his skull, caused by the removal of some depressed fragments. When he came under my observation the depression, of the size and shape of the bowl of a common dessert-spoon was filled up by a very hard and yellowish-coloured substance, the margins of which were exactly fitted to those of the depressed surface. In fact, such were the appearances that I, at first, took the case to be one of necrosis of the skull. From the man's account it appeared, however, that many years back he had had several pieces of bone removed after a compound fracture of the skull with depression. Having recovered, and being fearful as to the consequences which might arise from a large portion of his brain being thus exposed, he ultimately bethought himself of allowing the secretions and the dirt to accumulate in this spot so as to form a mass, which gradually increasing, had in the course of years formed a hard cake exactly moulded, by a little management, to the depression, which it completely filled up. Such was the history of this hard yellowish-looking substance, of which this man appeared to be not a little proud.

It is time, however, that I should proceed to the subject of fractures of the base of the skull.

Fractures of the base of the skull are either direct or indirect. That is, the bones either give way at the spot which was actually struck, or at a point more or less remote from the original seat of the injury.

In the vault, we found that fractures were, for the most part, direct; in the base, direct fractures are, comparatively speaking, very rare.

Hidden and protected as the base of the skull is by all the parts which are placed around it, rarely do we find that any force can be brought to bear directly upon the bones of this region.

Let us bear in mind, however, that at certain parts of the base of the skull, the bones are remarkably thin and brittle, for instance, the orbital plates of the frontal bone, the upper part of the ethmoid, that part of the middle fossa immediately corresponding to the articulation of the lower jaw, the cerebellar fossæ of the occipital, in all these different regions you will find that the bones are so thin that they are all but diaphanous. These bones are well protected by the parts which surround them; but, if direct pressure should be brought to bear upon these fragile structures, they may readily give way. Thus, scissors, slate-pencils, tobacco-pipes, bayonets have been thrust into the skull through the orbits, the nostrils, and the occipital bone, and the condyle of the lower jaw has even been driven into the middle fossa of the skull.

Thrust wounds in these regions, and especially those of the orbits and of the nostrils, become then of great importance

from the readiness with which the brain may be injured, through these thin bones at the base. No class of cases demands more vigilance on the part of the Surgeon, and by no class of cases does he run a greater risk of being put off his guard. Oftentimes has it happened that the brain-symptoms have not made their appearance for several days, the wound itself, to all appearance of the most trifling nature, having been scarcely, or not at all, noticed.

Injuries of this kind occur most commonly about the orbit.

In a case mentioned by Morgagni, a man, 30 years old, who had been struck over the right eye with a sharp pointed instrument, passed three days without sensible symptoms. On the fourth day, however, he went, of his own accord, to the Hospital, and there he died, much to the surprise of the Medical men, as all that had happened was simply a contusion on the right eye. At the examination of the head, the instrument was found to have passed through the upper wall of the orbit, and into the brain, reaching to within a finger's breadth of the ventricle.

In Sir Astley Cooper's case, the upper eyelid of a girl, 12 years old, was wounded by her falling upon a pair of scissors. Nothing to cause alarm occurred until the fifth day, when she was seized with convulsions, and subsequently complained of intense head-ache. These symptoms continued at intervals, and she died on the seventh day. A hole, large enough to admit the point of the finger, was found in the upper wall of the orbit, and corresponding to this, there was a wound in the brain, the surrounding parts of which were inflamed.

Mr. Guthrie mentions two cases of a similar nature. One, that of a boy, who was struck by a playfellow with a thick iron-wire on the right eye. He was seen, for the first time, two days after the accident. No external wound could be detected; but, as there was some bloody chemosis at the upper part and inner side, there was a probability of the wire having penetrated deeply, although no opening could be discovered with the probe. Shortly after the accident, it appeared that he had vomited, had eaten but little since then, but did not think himself ill. On the fourth day he began to complain of sickness, headache, and pain over the brow. On the evening of the fifth day he became restless and delirious, with some convulsive twitches of the face and arms. He died during the sixth night. The iron wire was found to have passed under the upper eyelid, between it and the eye, through the back part of the orbital plate of the frontal, and into the anterior lobe of the brain, which was here softened, and bedewed with matter.

The other case was that of a woman who was struck on the left eye with a tobacco-pipe. She had pulled a piece of the pipe out which was sticking in the orbit; the eye itself was uninjured: the wound was under the lid, between it, and the upper and inner side of the eye. A probe was passed some distance along the course of the wound. She had no symptoms for a week, when nausea, headache, and shiverings made their appearance, with paralysis of the upper eyelid. That night she became delirious, and died two days afterwards. Half an inch of the red-waxed end of the pipe had gone through the sphenoid bone, by the side of the sella Turcica, and lodged in the brain, from which it was removed bedewed with pus, the brain around being yellow and softened.

Mr. Guthrie states also that he had seen two other cases in children, of a nearly similar nature, and terminating in the same way.

In the winter of 1814, (b) a lieutenant in a Highland Regiment, when running on a dark night to escape from a shower of rain, came rather violently in contact with an irritable old man, who made a thrust at him with an umbrella, the point of which struck him immediately beneath the left eyebrow. The injury was attended with so little pain, or shock to the system, that this gentleman was able to walk at least half a mile to Sir P. Crampton's house, to show him the eyelid. The wound was three-quarters of an inch in length; the conjunctiva was not injured, neither was the eyeball. Two points of suture were put into the wound, and the patient walked to his lodgings. When seen on the following morning, this gentleman was at breakfast, and made no complaint, save of some stiffness in the eyelid. The next morning, however, Sir P. Crampton was called to him in a hurry, and found

(b) Dublin Journal 1851, p. 352.

him in strong convulsions, so strong that two persons were with difficulty able to keep him in bed. The convulsions continued with short intervals of coma, until the evening, when he died. At the examination of the head, it was found that the brass ferule of the umbrella, nearly two inches in length, had penetrated through the orbital plate of the frontal bone, and was lodged in the substance of the left hemisphere of the brain: it was imbedded in a thin coagulum of blood, which extended into the left lateral ventricle. Both ventricles contained a small quantity of bloody serum.

A soldier of the 77th Regiment, (c) being drunk, was put in the guard room, and the following morning was sent to the Hospital with some slight complaint, but nothing which appeared to call for particular attention. He was in the Hospital one or two days, and was walking about, when on a sudden he was attacked with symptoms resembling apoplexy, and died in a few minutes. No external appearance had been observed to indicate that any injury had taken place. On raising up the brain a collection of puriform fluid was found in the left anterior lobe, where it rests upon the left orbital plate of the frontal, and into this abscess was seen penetrating a piece of a tobacco-pipe about two inches in length. The piece of clay-pipe was supported by the left eyeball, having also as a support a circular hole in the left orbital plate. On further examination an ecchymosed spot was detected in the upper eyelid, which proved to be a wound made by the piece of pipe, which having entered the orbit, had passed through the orbital plate of the frontal, and thence into the brain. The inference drawn from the post-mortem examination was that the man, going home drunk, with a pipe in his hand, must have fallen, and thrust the tobacco-pipe into the orbit.

The cases of thrust wounds into the orbit which we have just been considering, were all difficult of diagnosis, most insidious in their course, and fatal in their issue. Such unfortunate results do not, however, always follow these thrust-wounds, even when the brain itself is seriously injured.

A child, (d) four years old, fell, and a common cheese knife, with a blade about four inches and a quarter long, and three-quarters of an inch wide, entered the orbit nearly horizontally, to the depth of three inches and a quarter, immediately beneath the superciliary ridge, and wounded the brain, injuring in its course the optic nerve, and probably also the levator palpebre muscle or its nerve. The father of the child stated that it required all his force to dislodge the knife from its situation. The bleeding was very slight, but the protrusion of some brain-substance followed the removal of the knife, and about eight days afterwards some more came away; notwithstanding which the child gradually recovered, without any exfoliation of bone, and he was known to be alive and well seventeen years afterwards.

Again, Morgagni quotes from Nebelius another case of a young man, who, on being wounded through the left orbit, was immediately attacked with paralysis on the same side, and convulsive motions on the opposite side: he became speechless, and soon afterwards was delirious. Then came pain in the right ear, followed in about three weeks by a slight discharge, which went on for some days, and, in about six weeks from the receipt of the injury, the patient was quite well again.

And here let me call your attention to a case which, for many years past, has been quoted as one of extraordinary recovery after a severe thrust-wound through the orbit. The case is that of François de Lorraine, Duc de Guise, who was wounded before Boulogne by a lance, which, as quoted by Boyer and many other surgeons, from Ambroise Paré, is represented as having struck the Duke above the right eye, inclining towards the nose, and entering, passed through on the other side, between the neck and the ear, with such violence that the head of the lance and a great part of the wood were broken and remained in, and could not be removed without the aid of a farrier's pincers, and yet, notwithstanding all this violence, the patient recovered.

On referring to Boyer (e) you will, I say, find the case placed under the head of "*Lésions du cerveau et des membranes par des instrumens piquans*;" and such, no doubt, would have been the nature of the injury, had the wound really been above the eye; but, in truth, the wound was not

above, but below the eye, and the lance therefore never penetrated the skull, but merely passed under it. In M. Malgaigne's (f) edition of the works of Ambroise Paré, the case is given in the very words used by this celebrated Surgeon himself, who instead of "*au-dessus de l'œil*," states the wound to have been "*au-dessous de l'œil*." The mistake, you will perceive, is one which might readily occur in French, so nearly alike are the words "*au-dessus*" and "*au-dessous*." Hennen, I see, also mentions the wound in this case to have been above the eye.

The error into which Boyer has fallen is clearly pointed out by M. Vidal de Cassis.

A thrust wound through the nostrils may also easily reach the brain, and that too with little or no outward mark to indicate that any severe injury has been received; and here we shall again have the same difficulty as to diagnosis, and oftentimes the sudden appearance of severe brain-symptoms, with nothing to lead us even to guess at the cause of all the mischief.

A trumpeter (g) of the 12th Lancers, aged 30, was admitted into the Hospital in February 1851, and was seen by the Assistant-Surgeon at the morning visit, who found him in bed, and considered that his ideas were somewhat confused, but attributed this, in part, to indulgence in drink the previous night. The patient on being questioned as to what was the matter with him, stated that on the previous evening he had been fencing with a walking-cane with some of his companions, and that he had received a blow on the nose, or a thrust from the cane in the face; but the only appearance of anything like an injury was a small puncture on the left ala of the nose, which did not appear larger than the wound from a leech-bite. He was somewhat taciturn, but was perfectly sensible, and answered readily the questions put to him. On the following morning there were still no alarming head symptoms, and consequently no particular examination was made of the parts where the wound existed. It was evident, however, that the man was labouring under a considerable degree of stupor. Towards the afternoon he became violent, and struggled with the attendants, who were obliged to use force to keep him in bed; his breathing was stertorous, and he puffed with his lips; the right eye was staring, and its pupil greatly contracted; the left pupil was widely dilated, and there was ptosis of the lid. He had passed everything under him; still, on calling him sharply by name, he sat up, threw his arms about, and struck at, or took hold of, any object within reach. In the evening he was suddenly seized with violent convulsions, attended with great discoloration of the face, and he died. No suspicion ever arose in the minds of the Surgeons who attended this man, as to the brain having been injured by a foreign body penetrating through any of the thin bones at the base of the skull; but at the examination of the head, the scalpel suddenly struck against a metallic body, just as the optic nerves were being divided. This proved to be the brass ferule of a small walking-cane, which, projecting into the skull, upwards and backwards, was lying close to the left side of the sella Turcica, and pressing upon the left optic nerve. Further dissection showed that this brass point belonged to the broken end of a cane, which had pierced the left ala of the nose, at the junction of the cartilage with the bone; and, taking a direction upwards, backwards, and a little inwards, it had grazed the inferior and middle turbinated bones, passed through the sphenoidal sinus, and thence into the skull, breaking off, and carrying before it the posterior clinoid process, but not rupturing the visceral membranes, which were, however, extensively inflamed.

But, if we find so much difficulty in recognising these direct fractures of the base, even in cases where there is a history of a thrust-wound, which might at any rate awaken our suspicions, what are we to say about those cases of direct fracture of the base produced by the condyle of the lower jaw being forcibly driven against its fossa? Such an injury, it is true, occurs very rarely; but we must not forget that the almost diaphanous state of the middle fossa of the skull, at the spot corresponding to the articulation of the lower jaw, renders this bone liable to an accident of this kind.

A boy, aged 12, was admitted into St. George's Hospital in February 1853, having fallen from the top of a house into an area. He was perfectly insensible, never rallied, and died

(g) Dub. Jour. 1851, p. 347. Dr. G. Anderson, 12th Lancers.

about four hours after his admission into the Hospital. There was general contusion of the brain, but that to which I would more particularly draw your attention at present is the peculiar fracture of the middle fossa of the base of the skull, exhibited in this preparation, belonging to the museum of St. George's Hospital. In this preparation may be seen a hole in the base of the skull corresponding to the bottom of the left glenoid fossa, and through this hole you may perceive the condyle of the jaw, projecting slightly into the cavity of the skull. There were several other very severe injuries in various parts of the body, which I need not describe.

In this case we have then a direct fracture of the base produced by the condyle of the lower jaw being forcibly driven against its fossa.

There is, however, on record, a still more singular case, in which the condyle of the lower jaw was driven right into the skull, where it was found at the death of the patient, which took place six months after the accident.

A French sailor, Brochard by name (h), whilst drunk, was thrown out of a second-storey window, on the 22nd of December, 1833. He fell upon his chin, and was immediately conveyed to the Naval Hospital. The most prominent symptoms were those connected with the mouth, which it was all but impossible for the patient to open, the jaws being closely set, and the lower one driven backwards and to the left; the under part of the chin was bruised. The temporomaxillary region was painful, and particularly so on the right side, where there was a slight bruise. Antiphlogistic remedies were resorted to, and the condition of the patient soon began to improve; the motions of the lower jaw gradually became easier. He was discharged from the Hospital in January 1834, still feeling some difficulty in moving the jaw, and in swallowing. It had been noticed, however, that ever since his fall this man had been subject to head-aches, and that his disposition was very much altered—from active and light-hearted, he had become indolent and taciturn. Still complaining of his head, he was shortly afterwards re-admitted into the Hospital, whence he was soon discharged again. In this state poor Brochard was sent on board the Triton, where he was placed under the care of the Surgeon, and carefully watched, as it was thought that he was shamming in order that he might be dismissed from the service. Violent pain in the head was still complained of, and there was great difficulty in swallowing. In the month of May he was sent to the fever-ward, where he was bled, after which the pain in the head became less, and he was again discharged. On the following morning he was once more sent to the Hospital to have the state of his mind carefully inquired into. By some mistake or other he was unfortunately again passed on to the fever-ward, where the Surgeon, who had but just sent him out, not being able to detect anything materially wrong about him, again discharged him on the following day. He then returned on board, and there he remained until the 31st of May, when he was seized with violent convulsions. On the 1st of June he was once more sent to the Hospital, and there he created such a disturbance in the ward, that it was found necessary to put him under restraint. On the following day the convulsions had become more violent, with great congestion of the face; he was bled largely. Matters went on from bad to worse, and the poor fellow died on the morning of the 3rd. At the examination of the head, the right condyle of the lower jaw was found projecting into the middle fossa of the skull, into which it had been driven through a starred fracture of the glenoid cavity of the temporal bone. The neck of the condyloid process was partially destroyed. Some spicula of bone had wounded the dura-mater, which was extensively inflamed and thickened. There was also a large abscess at the under part of the middle lobe of the brain. The post-mortem was done in a hurry, and the condition of the lower jaw on the left side was not thought of.

This in-driving of the condyle of the lower jaw into the skull through the thin diaphanous plate of bone forming the bottom of the articular portion of the glenoid cavity, certainly reminds one very strongly of a somewhat similar accident which has been known to occur, now and then, about the hip-joint. I refer to those cases in which the head of the femur has been driven into the pelvis through the thin plate of bone at the bottom of the acetabulum.

## ORIGINAL COMMUNICATIONS.

### THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.

Consulting Physician to the Hanwell Asylum.

#### NO. 4.—MELANCHOLIA PASSING ON TO MANIA.

In the engraving from the photograph accompanying the present paper, there will be found certain modifications of action of the muscles of the face differing from those in the three preceding ones; as in the present instance the patient, after being insane some months, and then falling into utter despondency, and continuing in that state for a month, was in a transition state towards mania. Her story is but one in a large chapter of such which London furnishes. She gained a small livelihood by the occupation of a sorter and folder of paper, and lived but poorly. After a confinement she had an attack of puerperal mania, lasting about six months; her conversation was generally incoherent, and her actions were sometimes impulsive and violent. She repudiated her infant, declaring that it did not belong to her, and on one occasion she leaped out of a window fourteen feet from the ground. About a month after being received into the Surrey Asylum the excitement left her, and great despondency supervened. She then sat all day in one position, or else stood up covering her face with her hands. She never employed herself, and would not reply when spoken to. For many months she remained in this state, and then what at first appeared to be recovery took place, and her faculties seemed to revive. The melancholia, however, soon returned, and continued six months more. Then, a sudden renewal of bodily and mental energy occurred, and she became maniacal; began to dress herself fantastically, sung songs, and indulged in various ideas connected with wealth and pleasure, in which state she at present remains. The photograph, taken when the state of melancholy was passing into that of excitement, retains something of the fixedness of attitude and expression in the first state; as in the arms held close to the body, and the position of the lower extremities, and in the downward tension of the cheek. The body is thin, and the hair is lank and heavy. But the eyes are not lost in vacancy; they seem to discern some person or object which excites displeasure or suspicion. The forehead is wrinkled with some strong emotion, and the eyebrows, although corrugated, have not the tense contraction toward the nose which is observable in many cases of melancholia. The lips are not drawn down at the angles, but, although well shaped, are somewhat compressed, and the lower jaw indicates some half-formed determination. The maniacal condition of this patient has been accompanied with such an increase of stoutness that subsequent photographs are scarcely to be recognised as being likenesses of the same patient. Her face has become broad; the angles of the mouth are a little drawn up, giving it an expression of merriment; her forehead is smooth, the hair is well arranged, and the eyes and eyebrows are significant of animated observation, whilst the whole attitude is perfectly free from constraint.

These changes are not only curious and amusing, and highly characteristic of the various moods of disordered mind, but lead to reflections of wide extent on the profound relations even of facial expression with anatomical arrangements peculiar to man, and with some of his highest social endowments.

It is probable that among those who have honoured these fragmentary contributions to the science of Medical observation, as it relates to the facial expression of mental maladies, there are some whose attention to the subject of physiognomical peculiarities may previously have been merely occasional and very general, and to whom the relations discoverable by minuter observations will be as novel as they are interesting. In the papers and engravings already presented to the reader, the various facial character that is independent of conformation of the bony and immoveable parts of the face has been sufficiently dwelt upon, and shown to lead the reflection to the elaborate muscular arrangements, apparently designed by the Creator for the expression of all human emotions and passions.

Among the peculiarities of the melancholic face, the drawing down of the angles of the mouth has been seen to be constant; and the corrugation of the eyebrows, their traction especially toward the nose, has been shown to be almost general. In an exhilarated state of mind, and as we shall hereafter see, in maniacal excitement, the angles of the mouth are usually elevated, and the eyebrows assume a different character. But it might be forgotten that these peculiar facial changes, these peculiar depressions or elevations, and the frowning its opposites, are effected by muscles which man alone possesses; and that animals are incapable of the wide range of man's highest facial indications in consequence of their absence; the anatomical peculiarity being in accordance, doubtless, with their incapability of the higher emotions; all their expression being limited to the characteristic passions or emotions of animal existence; to which not only their nervous structure but their muscular arrangements are exactly adapted.

The extraordinary strength of expression in the human lips, arising not only from the action of the angular depressors and elevators, but of the orbicularis muscle, is never seen in the lower animals. These muscles are in them wanting; and their absence accords with their want, if it may so be called, of the various human emotions which are among the endowments of man, and to which the power of facial expression is accorded. The infinite variety of facial expression is, in fact, given by the anatomical relations of the numerous muscles of the human face with moveable integuments. In looking at an engraving of the muscles, the integuments being removed, their great number, and the circumstance that all of them, except the two which move the lower jaw, are cutaneous muscles, cannot but impress the observer with the extent of the provision made for facial expression. Some of the muscular fibres are even so delicate, and so interwoven with the fat and cellular membrane, as to make their demonstration by the anatomist very difficult. It curiously illustrates the relation between the minutest arrangements of the great Author of life and His higher designs, to find how intimate seems to be the connexion of these and other anatomical facts and the superiority of man over animals.

Some observations in relation to this subject may perhaps be ventured upon in subsequent papers.

After a somewhat careful examination of the few published illustrations of Insanity of former years, representing cases of several varieties of the malady, copied from patients then living in asylums, I am disappointed to find that, with some exceptions, I cannot confidently recommend them to the student who is desirous of becoming acquainted with the modifications of face now generally seen in instances of mental disorder, or with the wider impress of the malady on the gesture, attitude, figure, and dress of the patients; all of which combine to complete the external characters of disordered mind. It is observable that nearly every one of the subjects is represented, in former illustrated works on this malady, as being in some form of mechanical restraint. That mode of treatment excited irritable patients to violent muscular exertions, accompanied with ferocious distortion of the features, and plunged the melancholic into deeper woe, aggravating their delusive fears, and perpetuating the silence and immobility of sorrow or of dread. The figures which the artist or the physician could then select from the crowd of the mad, in the terrible abodes of such affliction, were but figures particularly representative of the general objects abounding in the wards, and of which the memory dwelt in the casual visitor's mind long after visiting them. I could yet point out galleries and wards at Hanwell where, on opening the door, the visitor's eyes and ears were at once subjected to the most distressing impressions, and where, after the abolition of the practice of mechanical restraint, any disturbance or outrage became rare and exceptional. When no terrific patient was seen walking up and down with hurried steps, his chest and arms bound up in leather and strong cloth; and none any longer were beheld fastened with leg-locks, or degraded by handcuffs, hobbling about helplessly, or sitting silent and sullen, or muttering and cursing, by the gloomy walls, to which some of them were chained,—a change came over the faces of all the rest of the patients; and the characters of terror, or of compassion mingled with anger, were seldom displayed by their companions. With the departure of these indications of helpless and indignant feeling, angry and hateful words ceased also. In some of the wards, which it was scarcely safe

to pass through before that time, except with some especial precautions, the change was so extraordinary that on looking back upon it, after the flight of nearly twenty years, it might seem as if some illusion had become entwined with the memory of those past days, if the change had not been recorded and printed at the time, and the story laid before those who had opportunities of witnessing it, and of verifying it themselves. The very descriptions of madness in the older writers, and even in Sir Charles Bell's work on the "Anatomy of Expression," with its beautiful illustrative drawings, would appear to the more modern observer as exaggerated.

Such transformations have followed wherever such modifications of treatment have been introduced. Among many gratifying proofs of it, in establishments from time to time visited by me when the changes were in progress, not quite without anxiety, an indelible impression remains of what I saw in two visits, made within an interval of two or more years, to the asylum for naval lunatics, attached to the fine hospital of Haslar. When first seen, that small asylum was a condensation of the worst parts of the old treatment. Close to the sea, where all the patients had served, and some of them had been distinguished, the view of it was entirely shut out by high walls. There were pleasant plots of grass here and there within those gloomy boundaries, but there were also strict injunctions that no patient, of whatever rank, should walk upon them. To a large proportion of beds some apparatus or other of restraint was affixed for nightly use; and assuredly calculated to keep sleep and rest and peace afar off. Every arrangement was, of course, conformable to the same system, then thought indispensable; and to reflect on which excited in official persons an evident suspicion of some disaffection to the Government itself, of which the official orders were solemnly quoted as sanctioning what long custom had almost sanctified in their eyes. I well remember the proud and morose expression then prevalent among the officers immured there; and the tumultuous actions and violence of the commoner sort of sailors—maniacs. One of them who was handcuffed exultingly told me that he had worn the handcuffs twenty years, because he had murdered a man. I saw no arrangements for the employment of the patients, nor any contrivances for their amusement; and every face wore the expression of listlessness and apathy, or of anger, or a ferocity only overmastered by fear.

At my second visit all was changed. Every instrument of restraint had disappeared. The high walls had been lowered, and pleasant seats placed in look-outs from which the eyes of the old sailors beheld the sea, and the harbour of Portsmouth, and ships innumerable, and the Isle of Wight; with the hourly changes of light and shadow on the fresh waters and the lovely land. Nor were the effects unreadable in the hardy faces of the veterans in the asylum. Several of them now conversed cheerfully, and were allowed to go out to sea on fishing excursions with their excellent physician, Dr. Anderson—now no more—but who had effected all this good. Among a variety of gratifying results from this change of influences on disordered minds, some patients began to speak after many years of obstinate silence; and my old acquaintance of the handcuffs, no longer handcuffed, had become a reasonable man; talked no more of murder, but chiefly devoted himself to making balls, covered with gay pieces of leather, for little children. Ferocious passions had died away; and endearing feelings, long buried, were resuscitated and flourished as they might have done in this poor man's boyhood.

The readers of these reminiscences will, I trust, pardon my too evident inability to dissociate from the subject of physiological indications the photographs, if they may be so called, left in the brain, and frequently recurring reflections on the circumstances which cause the modern portraits of insane persons to form so strong a contrast with those collected merely by vision in the olden time, but which are fixed indelibly in the recesses of the mind; repositing where nothing in reality seems quite to die, among the records of imperishable and mysterious memory.

We may still occasionally see, in all asylums, the recent maniac walking energetically, fiercely, perhaps, up and down whatever space is allotted to him, and defying gods and men; but we feel almost a certainty that, before even many weeks have elapsed, those fierce eyes will be more mitigated in expression, and the strained facial muscles will be nearer to a state of repose, and the violent movements of the arms and

legs will subside, and even the upstarting hair will be less wild and irritable-looking. In former times we should, perhaps, have found him, after many months, chained to a pillar, or a post, or the floor, or his bed; still frantic; pale; sinking into melancholy sullenness, or debility, and death; but still wasting his heart in morbid violence of words and manner, and, as far as his bonds permitted, in revengeful action. So also we may still see the victim of melancholia sitting motionless, and wrapped in gloom, the eyes fixed, the angles of the mouth drawn tensely downward, or laterally so as to make the mouth a line between the compressed lips; giving, with the unobservant dreamy eye, the general expression which we recognise as the *suicidal look*; and which look warns the experienced attendant that the most unremitting care continues necessary. But still, no unkind measures being resorted to, and no bonds superadded, and cheering and compassionate words being daily addressed to the desponding or terrified sufferer, sometimes the eyes become for a moment irradiated, as if with hope; the muscles of the cheeks relax into an encouraging or grateful smile, and the mouth re-assumes its natural expression. And such slight physiognomical changes, evanescent it may be, are still the precursors of coming recovery.

I must again refer the student interested in the general subject of physiognomy in relation to the various forms of insanity, to the plates already mentioned as having been published by Esquirol, and accompanying the last edition of his great work "*Des Maladies Mentales*," 1838. There are in the first volume of that valuable work (p. 408 et seq.) descriptions of two cases of melancholia which, with the portraits (No. II. and III., of which wood-cuts are

given with this paper), may well occupy careful perusal and inspection. The first of these relates to a young woman, twenty-three years of age, who is represented sitting on a bench which she always occupied when obliged to quit her bed. Her arms are crossed, and her feet. Her look is averted, and her eyes are fixed on the ground; her arched brows seem drawn strongly towards the top of the nose; her lower lip is depressed, and the upper appears elevated. Her dark hair is neglected. This young woman scarcely ever spoke or moved, and she took food with extreme reluctance; sometimes only overcome by a cold affusion. From that face all comfort and hope have fled, and from her figure all signs of activity or animation. Some single thought, or some train of torturing thoughts, or some fixed and fearful impression, would seem wholly to possess her mind. She had

lived in the country in the stirring years of the Imperial conquests, and had been terrified by the soldiers passing through retired villages, with little regard for the inhabitants. The portrait is evidently faithful; and it also curiously represents a large class of melancholy cases; so strongly do the fixed positions of the mind govern facial character and attitude, and exclusive expression.

In the next engraving in Esquirol's collection we find a different representation of a life-long melancholy; fixed and intense, but without the immobility represented in that just spoken of. A female figure is seated on a bed; the lower limbs drawn up, one hand grasping a knee, the other arm on the pillow, and the hand supporting the head. The features of the face are striking, and show that once that face must not only have been handsome, but characterised by forms usually associated in the mind with high birth, although by no means constant in that rank. The mouth and chin, after years of sorrow, or of hope deferred, retain much of their delicate beauty, and the well-formed nose may be pronounced as remarkably consonant with the firm and faithful affections of the original. The eyes, which were blue, are large, and widely opened; the eyebrows are arched, and, with the muscles of the forehead, strongly drawn downward and toward the nose. The hair, once beautiful, now whitened with grief more than years, is copious, and curls in wild disorder. The arms, although thin, retain much of their delicate and symmetrical outline. The body is wasted, and the lower limbs, rigidly drawn up to the trunk, have long lost their power. The whole countenance has an intense and grieved expression; and the eyes, yet expressive, seem intently to regard or to expect the appearance of some object ever present to the mind.

The history of this patient was, in truth, one long and melancholy grief,—a real romance in a woman of high rank. She was a princess of one of the noblest of the French families, and brought up in splendour, and in all childish happiness. She grew tall and strong, and all the illusions of youth, and beauty, and high station were gathering round her. The time had scarcely gone by when, in the careless days of childhood, the young Duke d'Enghien was often her playmate in the splendid gardens of the Château of Chantilly. Soon afterward, the great French Revolution shook at once from rank, and power and wealth all the princes and nobles of the land.

The young princess was transferred to the obscure care of a private governess. She became acquainted with poverty, and disappointment and fear agitated her daily existence. Her education was neglected. The Duke d'Enghien unhappily re-entered France, and his life was the immediate forfeit. His murder filled Europe with grief and horror. To the princess, then sixteen or seventeen years old, it brought despair. She fell by degrees into profound melancholy, and, young as she was, the springs of her life being poisoned, her hair became almost suddenly grey. She was taken to the Salpêtrière, of which asylum she remained an inmate until, after many years, death came to her relief. Long before that release her lower limbs, partly from inaction and partly from habitual position, had become contracted, so that when she moved about it was on the hands and ossa ischia, like a cripple. In all those years she seldom spoke, and then only in murmurs. Her usual position was that represented in the wood engraving. She sat on her bed, her head leaning on her hand, and her large eyes fixed all the day long, and every day, on a window opposite to her,—as if looking for some one on whom those eyes were never more to gaze, or listening for some loved voice, never more to be heard by mortal ears.

## NAVY MEDICAL REPORTS.

### TWO MEN POISONED BY THE HERB ENANTHE CROCATI OR WILD CELERY.

By ROBERT GRAHAME, M.D.

Surgeon, H.M.S. Wellington.

On the morning of Saturday, the 13th of February, the barge of H.M.S. Wellington was ordered ashore at Cambelltown at 8 a.m. for the purpose of being scrubbed and the gear cleaned by the boat's crew. Close to the spot selected for their operation ran a small stream or burn, as they term it hereabouts, and along its banks grew in abundance the plant in question. The men had strayed along the stream and some of them had pulled up the plant, washed the roots or tubers and eaten them, their example being quickly followed by the rest, as is usual in such cases. They afterwards collected a further quantity, washed it, and brought it on board for their messmates, to the amount of perhaps as much as would have filled a ship's wash-deck bucket. For some time after the arrival of the men with the boat (about 10 a.m.), nothing occurred to induce any suspicion of the danger their imprudence had subjected them to, and unhappily four of the ship's company had partaken of the root in the meantime, among whom was William Walsh, ship's corporal, who ate four good-sized tubers.

About 10.20 a.m. I was summoned to the aid of Owen Gaffney, who was labouring under severe epileptic accession on the lower deck, having just recovered from an attack of the same nature, Mr. Ironson, my assistant, having allayed its intensity by the cold affusion. On my arrival the man was in a state of almost immovable rigidity, insensible, moaning and breathing stertorously; countenance livid; eyes fixed, pupils dilated; sanguineous foam issuing from the mouth; intense action of the dorsal and lumbar muscles, or opisthotonos; the pulse very feeble, and the heart's action even scarcely perceptible; lower jaws firmly locked, the tongue much injured and slightly protruding. The cold douche to the head was freely administered. My instant impression was that he was labouring under the effects of some deleterious matter taken while on shore; and having given utterance to my suspicion, one of the men said, "Yes, Sir, he has been eating a good deal of this root," producing a mess basin half full of the plant and root. Having no doubt whatever of the nature of the case, I had him at once moved into the sick bay, and with some difficulty forced him to swallow a little brandy. This appeared to relieve him somewhat, or the violence of the spasms relaxed spontaneously, and I at once gave him an emetic of the sulphate of zinc, there was, however, not the slightest return of consciousness; he lay gasping and foaming at the mouth; the pulse, which had improved a little, becoming again imperceptible, I gave him a liberal dose of the sesquicarbonate of ammonia, but to no purpose, for in eight

or ten minutes from my first seeing him he expired gently and without a struggle.

By this time alarm had seized on the majority of those who had eaten, both ashore and on board, and more than sufficiently alive to the necessities of their case, they came rushing tumultuously into the sick bay for assistance, complaining of feeling uneasy, although, in some cases, without prominent symptoms. To all I administered the zinc emetic instantaneously, followed by copious draughts of tepid water, and, subsequently, brandy and ammonia, as seemed requisite; in most the stomach did not respond readily to the emetic, and in others not at all, although they used every effort to induce vomiting, by means of draughts of tepid water, tickling the fauces with feathers, and pushing the fingers into the pharynx. In five of the cases, including the man who died, the spasmodic accessions were severe and successive; in one the more prominent symptom was extreme restlessness, approaching to mania; in almost all there was semi-delirium and jactitation, if not convulsion; and in one or two prostration, requiring repeated small doses of brandy and ammonia. In two of the cases the men had said nothing, expecting I suppose to brave it out, when they suddenly fell down in convulsive fits on the fore-castle, and were carried into the sick bay.

William Walsh, ship's corporal, who had been assisting in bringing men into the sick-bay, and had actually reported Gaffney's death on deck, came back again to the bay to offer his assistance. He then smilingly, and seemingly without any fear of the consequences, told me that he had also eaten some of the root, but did not feel in the least unwell. I was preparing for him an emetic draught, when he said that he was beginning to feel giddy. I immediately gave him the draught, which proved most effective. He vomited copiously, and for some time kept up the action by feathers and warm water. His countenance improved, and in other respects he seemed to be much relieved; but, when about to be removed to his hammock, convulsions came on, and for two hours one fit followed another, until they terminated in his decease. He latterly required ammonia, brandy, sinapisms to the lower extremities, and assiduous friction.

In all the cases in which there were convulsions, opisthotonos was the form assumed. As we were hourly expecting to proceed to sea, the Procurator Fiscal came on board at once, and held a precognition, and Mr. Ironson opened the body of Gaffney. The surface was slightly livid; the stomach empty,—tough, viscid, tenacious mucus adhering to its mucous lining, which was highly congested. In the ileum small portions of the root were found. On opening the abdomen, and previous to examining the stomach, an overpowering and pungent odour of the plant at once became diffused, resembling that of celery seed; and in all the cases the patient complained of constant and continued eructations strongly flavoured by the plant, tendency to cramps in lower extremities; pain along the course of crural and sciatic nerves, commencing in the spinal column, more especially the lumbar region; vertigo, griping, or severe tormina; debility, and total loss of appetite for food.

### ON GUNSHOT WOUNDS OF THE EYE.

By W. WHITE COOPER, F.R.C.S.

Ophthalmic Surgeon to St. Mary's Hospital, &c.

Of the various injuries affecting the eye, wounds from shot and fragments of copper caps are among the most serious; the foreign body is driven with great force, and even if the elasticity of the tunics causes it to glance off, the concussion may seriously affect the globe. The destruction of eyes from accidents of this description is more common than is imagined; M. Boissonneau states that of 939 persons between the ages of 6 and 15 whom he fitted with artificial eyes, 341 had lost an eye either from the effect of firearms or the explosion of copper caps.

The immediate effect on the system of a shot striking the eye varies according to the idiosyncrasy of the individual; in some instances the person becomes sick and faint, though the injury may be trifling; others, whose nervous systems are less impressionable, treat the accident with indifference, though the eye may be seriously damaged. Our judgment as

to the severity of the injury must therefore be formed irrespective of the opinion of the patient.

A shot striking the eye may cause simple bruising and concussion; or it may glance off, cutting a groove without penetrating; it may pierce through the tunics and lodge in the globe; or, lastly, it may traverse the eye and bury itself in the orbit.

The first accident is usually the effect of a spent shot; in the others the shot retains its velocity. In the large majority of cases it has glanced from a stone or tree, and is flattened, angular, or jagged. It is remarkable how frequently, when one shot strikes a person, the eye is the seat of the injury.

*Concussion of the eye from spent shot.*—Major M., aged 42, consulted me in January 1856. The previous day, while shooting with a party, he was struck by a glancing shot on the left eye. He felt a smart stroke, and the sight was extinguished. No blood flowed, though much became effused under the conjunctiva. Six leeches were applied the same evening, and the eye was frequently bathed; during the journey to town, which occupied four hours, it had been covered with a handkerchief.

Its condition was as follows when examined by me:—Pupil dilated and motionless; the whole surface of the sclerótica covered with effused blood, but no breach of surface could be discovered; humours of the eye clear.

The treatment was, repose in bed in a darkened room, cold-water dressings to the eye, a brisk purgative, and strict abstinence.

On the third day large objects became visible to the injured eye, and day by day the sight improved; the severity of the discipline was gradually relaxed, and when the Major left town at the end of ten days, the eye, though still weak, had nearly recovered its power of vision.

*Wound from glancing shot.*—*Concussion.*—On February 16, 1854, Mr. M., aged 60, was rabbit-shooting with a friend in Hampshire, when a shot glanced and struck his right eye, the sensation being similar to that caused by a blow from a twig. The sight was not immediately extinguished, but speedily became so. He went home, and a surgeon happening to be in the house, attended to the eye; he washed it, cleansing away some blood, ordered a poultice, and advised Mr. M. to proceed at once to London. This he did, reaching town at 10 p.m., having suffered severe pain during his long journey. At 11 p.m. I saw him. The upper lid was red, and swelled at the margin; there was little congestion of the eye, but he could only discern light from darkness. As it was undesirable to expose the eye to candlelight, my full examination was deferred till the morrow, cold applications being ordered.

At 9 a.m. on the following day the condition of the eye was ascertained to be as follows:—The inner side of the cornea presented an abrasion, extending from an ecchymosed spot on the sclerotic just beyond the junction; beyond this there was no wound; there was little redness, and the pain had gradually subsided. The pupil was dilated and motionless—no sight. This gentleman was of spare frame, and very temperate. He was desired to keep perfectly quiet in a darkened room, on low diet, and to continue cold applications to the eye.

On the 20th, perception of large objects returned, and the eye was progressing favourably. On the 22nd, finding an increase of congestion, six ounces of blood were taken by cupping from the right temple, with marked benefit. By the 26th the eye was clear from inflammatory action, and the strict regimen which had hitherto been enforced was relaxed; the sight was greatly improved.

Mr. M. returned home on the 28th. The eye bore no trace of the accident, and the only difference between the sight of the two eyes was a slight haziness in that of the right.

*Eye lid pierced by shot.*—*Eye grazed.*—Lord C. was cover-shooting with a party, December 29, 1856. Two shots struck him: one just grazed the upper lid of the right eye; the second passed through the lower lid close to the outer canthus, and impinged upon the eye half a line below the cornea. There was free bleeding from the lid, and much ecchymosis of the eye; the sight was confused, but not seriously impaired. I saw him the following day. The ecchymosis was considerable, and an abrasion of the conjunctiva distinctly indicated the stroke of the shot on the eye. The sight was

still confused, and there were many *muscae volitantes*. Pupil sluggish. The treatment recommended was leeches, purging, abstinence, with cold applications to the eye; and at the expiration of a week the patient returned to his country seat with merely a little weakness of the eye remaining.

Considerable ecchymosis frequently attends bruising or grazing shot injuries, rendering it difficult to decide at the first glance whether the coats of the eye have been pierced or not. If the sclerotic be shot through, the wound will be indicated by its ragged edges, and by a dark mark showing the choroid; in some instances this appears as a distinct projection. If the anterior chamber has been opened, the aqueous humour will escape and the iris fall forward, obliterating the cavity and adhering to the wound. In one case I remember the cornea was just sufficiently ruptured to permit the fluid to escape; but there was no persistent gap, and the anterior chamber refilled in a few hours, the iris recovering its plane, and the pupil remaining circular. Nevertheless, as adhesion generally takes place, an irregular or elongated pupil is to be expected after gunshot wounds which have ruptured the cornea.

A shot or fragment of copper cap (for the observation is applicable to both) may lacerate the sclerotic, and yet by its elasticity be thrown off. The late Marquis of Anglesea had a fortunate escape of this sort. He was shooting from his pony in company with his private medical attendant, when, after a shot fired by the marquis, blood was seen on his eyelid and cheek. On examination the surgeon found that a piece of copper cap had cleanly cut through the outer side of the sclerotic of the right eye, the choroid projecting through the wound, resembling the head of a fly. Gentle pressure was made on this with a probe; it slipped back and did not reappear. Simple treatment only was used to the eye, and no ill effects followed.

After accidents to the eye from shot, the surgeon will be closely and anxiously questioned as to the probable result. A guarded answer is at all times proper. A slight graze may possibly by its concussion render the eye amaurotic, but when a shot has fairly penetrated the coats of the eye, the risk to sight is always most grave. In two cases within my knowledge (one in the practice of Mr. G. D. Fonnock, the other a patient of my own), the shot simply pierced the cornea and dropped into the anterior chamber, whence it was extracted without difficulty, the eyes receiving no permanent injury; but when the shot penetrates behind the iris, it either lodges in the interior of the globe, where it is sure to set up such irritation as to destroy sight—such, at least, has been my experience—or it tears its way through the eye, generally blinding, though not materially disfiguring it.

I regard the following as an instance of a shot passing through the eye:—

*Penetrating wound of eye.*—*Rapid recovery.*—In January 1856, Mr. V. S. aged 52, was woodcock-shooting in Ireland. He happened to be in a ravine when a shot from the gun of the keeper, who was above him on the opposite bank, struck his left eye, instantly extinguishing the sight. The following morning Mr. S. proceeded to Dublin, and placed himself under the care of Sir Philip Crampton. Singular to say, scarcely any inflammation arose, and though the eye was blinded, this gentleman speedily recovered from the wound.

He consulted me in November 1857, and the condition of the eye was then as follows:—Globe natural in size and consistence; iris natural in colour, but bulged forward by the lens, so that the black uvea at the margin of the pupil is strongly marked; the pupil is drawn upwards and slightly

outwards to a cicatrix at the margin of the cornea; the lens densely opaque, and the capsule slightly spotted with pigment, the conjunctiva somewhat vascular. With the exception of loss of sight, and some uneasiness at changes of weather, this gentleman suffers no inconvenience from his eye.

In determining the question as to whether a shot has penetrated or not, the following points have to be considered:—The weight of the shot, the distance from which it was dis-

charged, the position of the eye, and the direction whence the shot came. A heavy shot will plunge into the eye at a hundred yards, when a light shot would glance, or fail to enter at fifty. There is far more risk of a shot penetrating when it strikes the inner half of the eye than when the outer half is struck; and when the direction is very oblique, the angle of incidence will favour the escape of the eye. The elasticity of the tunics is such that a round pellet will be thrown off when an angular or jagged shot will pierce through them, and the laceration within the eye will depend on the size, shape, and force of the shot. An eye may present two wounds, marking the entrance and exit of a shot. The exit wound will be largest, the edges most ragged and everted, and will almost certainly be on the inner side of the eye.

If a small foreign body be driven with great force through the crystalline, it will make a minute opening in the anterior capsule, and a larger at its point of exit through the posterior. The first may be instantly closed by the elasticity of the membrane, in which case opacity will commence in the posterior layers of the lens, and gradually progress from behind forwards. The puncture, if in the pupil, may be recognised by a faint cloudiness in one spot; the rapidity with which the crystalline opacifies depends on the rent in the anterior capsule; if large, so that the aqueous humour be freely admitted, the lens soon becomes infiltrated and opaque. I have seen this occur one hour after injury.

When a heavy shot passes through the lens it ploughs it up; fragments may be thrown into the anterior chamber, and the whole body displaced, tilted against the iris or into the pupil; if, as is often the case, the iris is involved in the wound, a portion of it disappears altogether, the remainder being stretched by the opaque lens. As absorption of this progresses, more and more of the iris will appear, until there may ultimately be merely a displaced pear-shaped pupil, the extremity adhering to the wound as in the first woodcut. If the wound be at the margin of the cornea (as is singularly often the case), the aqueous humour may drain through it for some time, and the iris will lie against the cornea; but when the aperture has closed, the anterior chamber will refill, and the iris fall back to an extent depending on the adhesions which have formed, and the pressure caused by the lens.

When a shot passes completely through the eye, vision may be destroyed; but there is far less suffering than when it lodges. Considerable and protracted torture then attends its presence; yet in time this subsides, for nature does her best to relieve the irritation by enveloping the foreign body in lymph, and fixing it to one spot. Tolerant though the eye may be under such circumstances, a case is mentioned by Sir Charles Bell, in his "System of Operative Surgery" (a), which taxes our credulity. Speaking of the influence elastic tissues exert in arresting the progress of a ball, he says that a soldier received a musket-ball in the globe of the eye, where it remained. It was in that situation too valuable for him to consent to have it extracted! This man must have been much-enduring, or blessed with a singularly obtuse nervous system.

The amount and duration of suffering caused by a shot in the eyeball will much depend on its position. If it lodges in the firmer tunics, so as to be motionless, little suffering may arise; but when rolling about in the vitreous humour, it will be a source of great torment. If I were to name any special indication of the lodgement of a shot in the interior of the globe, it would be the colour of the iris. I have invariably found that this undergoes a striking change. A blue or grey iris will become olive, or even green; a hazel iris will assume a red hue. When the iris retains its natural colour and aspect, we may conclude that the shot is not in the eye; for the ultimate condition of an eye in which a shot has lodged is commonly as follows:—The globe will be soft, and diminished in size, from disorganization and absorption of the vitreous humour; the sclerotic puckered towards the wound, and of a brownish or yellowish tint; conjunctiva traversed by many dull red vessels; iris discoloured, and its fibres converging towards the distorted pupil, which is generally filled with tough whitish lymph. No perception of light, but occasional flashes are seen, and the eye is irritable at changes of weather.

(To be concluded.)

(a) Vol. ii. p. 452.

## ON THE MORTALITY OF THE METROPOLIS IN THE SUMMER OF 1857,

INCLUDING A NOTICE OF THE DIARRHŒA EPIDEMIC.

By J. J. FOX, Esq.  
Fellow of the Statistical Society.

### I. TOTAL MORTALITY OF THE SUMMER.

THE deaths registered in the thirteen weeks ending September 26 were 14,259. Making the usual assumption for increase of population, this amounts to a mortality of 534 to 100,000. But the average mortality of the past 17 summers (omitting those of 1849 and 1854 as exceptional) is 555. The summer that has just elapsed is therefore about 4 per cent. below the average, or may be said to have a "general salubrity" of 4 per cent. The summers of 1845, 50, 53, and 55, had a general salubrity greater than the present, i.e. their mortality was lower; in the other 13 summers of the series the mortality was greater.

### II. DISTRIBUTION OF THE MORTALITY AMONG VARIOUS DISEASES AND CLASSES OF DISEASE.

We may in the case of this summer divide the principal causes that together make up the total mortality into two heads, according as their mortality is above or below the average of former summers.

#### A. Causes of death *above* the average of former summers.

Diarrhœa . . . . .	41 per cent. above.
Whooping-cough . . . . .	18 " "
Croup . . . . .	6½ " "
Zymotic diseases (a) . . . . .	5 " "
Premature births and debility . . . . .	5 " "
Teething . . . . .	5 " "
Diseases of kidneys . . . . .	3½ " "

#### B. Causes of death *below* the average of former summers.

Bronchitis . . . . .	6 per cent. below.
Rheumatic diseases . . . . .	8½ " "
Typhus . . . . .	9 " "
Diseases of digestive organs . . . . .	9 " "
Phthisis . . . . .	10 " "
Paralysis . . . . .	11½ " "
Diseases of uncertain seat . . . . .	11½ " "
Apoplexy . . . . .	13 " "
Hydrocephalus, cephalitis, & convulsions . . . . .	14 " "
Diseases of the heart . . . . .	14½ " "
Diseases of respiratory organs . . . . .	14½ " "
Diseases of nervous system . . . . .	15 " "
Pneumonia . . . . .	19 " "
Measles . . . . .	20 " "
Erysipelas . . . . .	36 " "
Scarlatina . . . . .	44 " "
Small-pox . . . . .	82 " "

These numbers suggest the following remarks:—1. With regard to small-pox the per-centage below the average, though very great, is less than it was in the previous quarter (b), indicating, probably, that the disease has reached the minimum of its cycle, and is now beginning slowly to increase. The next one or two quarters will show whether this is really the case, or whether the slight increase may be only a minor fluctuation on the surface of the great wave, due, perhaps, to the excessive heat, or some other atmospheric peculiarity of the summer. It is remarkable that not a single death from small-pox is returned in the western division, and very few in the southern; the eastern division has little more than its share, proportioned to its population; while 36 per cent. of the deaths from small-pox occurred in the central division, the population of which forms only about 15 per cent. of the total metropolis. The proportion in the northern division was also high, but as it contains the Small-pox Hospital, no fair inference can be drawn.

2. A second striking feature in the morbid character of the season, as expressed in the above numbers, is the concurrence of a large number of important diseases, *considerably below* the

(a) The average with which the mortality from zymotic diseases is compared, is derived from the previous 12 summers, omitting the deaths from cholera in 1849 and 1854.

(b) The corresponding numbers for the six previous quarters, beginning with the commencement of 1856, are 18, 38, 52, 73, 78, and 89.

average, with some others as *greatly* above; in other words, there are few or none which are only *slightly* affected by the season, and but for the large prevalence of two causes, diarrhoea and hooping-cough, the quarter would have been a particularly healthy one. This may be shown by comparing the mortalities of the five largest causes of summer death, in this and former summers. The *usual* order is as follows; the numbers expressing the number of deaths per 100,000 of population, caused by each:—

Phthisis	.	.	.	.	.	68
Diarrhœa	.	.	.	.	.	62
Hydrocephalus	}	.	.	.	.	41
Cephalitis and						
Convulsions						
Typhus	.	.	.	.	.	23
Scarlatina	.	.	.	.	.	23

making a total (with omitted decimals) of 219, which is just 40 per cent. of the total mortality. Now the same five causes, arranged in their order of occurrence this summer, are—

Diarrhoea . . . . .	88	
Phthisis . . . . .	61	
Hydrocephalus	}	35
Cephalitis and		
Convulsions . . . . .		
Typhus . . . . .	21	
Scarlatina . . . . .	13	

These are still the five most important causes of death, except that bronchitis, hooping-cough, and pneumonia, all usually below scarlatina, have risen above it. It is curious that the sum of the 5 is still just 219, as it was in the average of former summers, but how differently is this large fraction of the total mortality constituted! Omitting diarrhoea, the four others, phthisis, hydrocephalus, etc., typhus and scarlatina, *generally* make a sum of 156 deaths in 100,000; *this year* they amount to 131, while diarrhoea has risen from 62 to 88 deaths, outtopping phthisis, and becoming the first cause in importance. We may therefore consider the inference substantiated, that but for the very large increase of diarrhoea, this might have been placed among the very healthy summers. It becomes an interesting problem to determine the character of this invasion of diarrhoea. Is it epidemic, in the sense of belonging to the cycle of former diarrhoea and cholera invasions, and coming perhaps from abroad, or is it an accidental increase of our regular summer disease, due to the very remarkable meteorological character of the season?

### III. METEOROLOGY OF THE SEASON.

The summer of 1857 was a peculiar one. Although the summing-up of meteorological elements, as registered by observers, is but a very imperfect expression of the "weather" of a period; yet it is the best we can get, and it is worth while to notice how the season we are considering stands, when compared with the same season of former years. June, July, and August are the three months, the character of which must have most influence on the deaths registered in the summer quarter.

1. The *mean temperature* was 64°, being 3½° above the average of the previous 16 summers, and only exceeded by that of 1846, which was three-tenths of a degree higher. June and July were each of them considerably above the average; August was higher than it has ever been during the 86 years of which we have trustworthy records.

Moreover, these three months are part of a warm period, extending from May to October; of the 26 weeks from the beginning of May to the end of October, only 4 were colder than the average of former years, while 22 were warmer.

2. The mean reading of the *barometer* was in each month above the average, but not to any great degree. Its range in the month was about the average in June and July, but much less than usual in August.

3. The amount of *rain* was slightly less than usual, being pretty much *above* the average in June, *below* it in July, and at its average value in August.

4. The *humidity* of the air was in each month less than usual, especially in July.

5. The amount of *wind*, as measured by Whewell's anemometer, was below the average in June, very much below in July, but in August rather greater than usual. As compared with the same months in 1856, the *distribution* of the wind is not very different in July and August, but June is marked by a much larger prevalence of east wind in this

year, which was also the character of the previous months, April and May.

### IV. THE DIARRHOEA EPIDEMIC.

So large a fraction of the mortality this summer was caused by diarrhoea, that it calls for a few remarks. Were speculation safe, one might be tempted to theorize as to the influence exerted by the various atmospheric circumstances with which it was attended. Facts, however, with all their fallacies, are safer than speculation, and I will present here the cycle of years, commencing with 1846, arranged in the order of their mortality from diarrhoea in the summer quarter. The number annexed to each represents the proportion of deaths to 100,000 of the population. These numbers, of course, have no pretension to be received as absolutely correct, but only as approximations. (a) I have also added to each year the mean temperature of the period, consisting of the four months from June to September:—

	Mortality from diarrhoea.	Mean temperature of June to Sept.
1849 . . . . .	108 . . . . .	60.4
1857 . . . . .	88 . . . . .	62.9
1854 . . . . .	82 . . . . .	58.7
1846 . . . . .	73 . . . . .	63.2
1856 . . . . .	62 . . . . .	59.6
1851 . . . . .	61 . . . . .	59.5
1852 . . . . .	59 . . . . .	60.4
1847 . . . . .	64 . . . . .	59.9
1850 . . . . .	60 . . . . .	60.9
1853 . . . . .	60 . . . . .	58.4
1855 . . . . .	49 . . . . .	59.5
1848 . . . . .	47 . . . . .	58.5

The average of these numbers, expressing the mortality, is 65, and only 4 out of the 12 summers are above the average, viz., the two cholera seasons, the present one and that of 1846. The cholera summers may be regarded as exceptional, though one of them is exceeded in its diarrhoea mortality by 1857. 1846 and 1857, therefore, stand out distinctly from the group as years in which the diarrhoea mortality was very considerable; and they are also remarkable and exceptional in the high temperature of their summer. It is worth noticing that 1849 was a summer above the average warmth; while 1854, in which the diarrhoea mortality was *less* than the present year, although cholera prevailed, had a summer of very low mean temperature.

The diarrhoea epidemic of this year may be regarded as having lasted 16 weeks, from the third week in June to the first in October, during which interval it caused 2490 deaths. Increasing slowly at first, it mounted rapidly in the early weeks of July, and reached its maximum at the end of that month, that is to say, in the week ending the 1st of August. From its maximum, the decline was gradual, taking nine weeks to subside into a quiescent state, while in ascending to the summit it had only occupied six weeks. A similar feature marks the curve formed by the averages of corresponding weeks in the previous 10 years, in which the course of the usual summer diarrhoea belonging to each year is blended with other years; the deaths increased slowly in June, rapidly in July, reach a maximum in the second week of August, and decline more gradually than they rose, until about the end of November they have sunk to about the same number that they were in the beginning of June. The maximum of the deaths from diarrhoea in 1857 was thus about two weeks earlier than the average maximum of former years; but it did not occur to the whole of the metropolis at the same time, for in the western division, taken alone, the week containing the maximum preceded, and in the southern succeeded the week which contained the maximum for the metropolis taken entire. It is probable that different parts of London differ not only in the relative amount of deaths caused by an epidemic, but also in its course, or the period during which it manifests its ravages. These and many other interesting points of like nature remain for future investigation. It should be noticed as bearing on the difficult subject of the connexion of meteorology with disease, that the maximum occurred in the week that followed the two hottest weeks of

(a) The error introduced by the estimate for population may be regarded as *nil* in 1851; whatever it be, it increases with each year after that epoch; yet its amount is always slight, and for the present year, 1857, does not probably exceed 1.7 per cent., or about a sixtieth part.

the season, when the mean weekly temperature reached the great height of 68°. For two consecutive weeks to present so high a mean temperature is a very unusual phenomenon in this country.

(To be continued.)

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### THE HOSPITAL FOR DISEASES OF THE SKIN.

#### REPORT ON THE NATURAL HISTORY, DIAGNOSIS, AND TREATMENT OF ALOPÆCIA CIRCUMSCRIPTA.

(Concluded from page 219.)

**PROPOSITION X.**—*That its anatomical characters are Wasting of the hair bulbs and Thinning of the affected parts of the scalp.*

If the scalp in a case of Alopecia circumscripta be shaved its thinned condition at the affected parts is remarkably well seen. Supposing the case a well marked one, the patches appear smooth, glossy, and somewhat tense, while the skin in other parts is much thicker and studded over with the cut ends of the hairs. If the hair be dark the healthy parts of the scalp look more or less blackened by the remaining portions of hairs within their follicles, while the diseased patches are of pale pink colour. To the finger the greater thickness of the healthy tracts is very perceptible. The thinning is no doubt due chiefly to the removal of the hair bulbs, but probably also in some measure to a general atrophy of the deeper layers of the skin itself with its secreting glands, and to the absorption of its adipose tissue. If a few hairs be drawn out from close to the border of the bald patch, it will generally be noticed that they come out much more easily than usual. The tapering condition of their extremities, which should be somewhat bulbous, is easily seen, without assistance, by a good eye. Under the microscope it is very apparent indeed. The extremity often tapers off to a mere point, and little or no pigment is seen near it. This tapering is often very gradual indeed, and extends to some length along the hair shaft after its escape from its follicle. It is thus clear that a certain amount of longitudinal growth proceeds subsequent to the commencement of the wasting process. The hairs are seldom brittle, and never show any tendency to split into filaments. Not unfrequently, however, they look as if broken off close to their bulbs, a result no doubt due to their extreme slenderness at that part. The writer has never in any single instance seen any appearances at all resembling those produced by fungoid developments, either within or upon the hair. On the contrary, the hairs have always seemed perfectly healthy, excepting the wasting of their bulbs. He believes that he has examined the hairs in nearly fifty cases.

The characters above described are for an obvious reason the best seen in cases in which the disease is advancing. The appended woodcuts show the condition of the hairs in Cases 2 and 3 in our series. For the sake of contrast, a hair with healthy bulb, pulled from an unaffected part of the same scalp, has in each instance been placed by the side of those which are wasted.

**PROPOSITION XI.**—*That it is not of parasitic origin, and that there is reason for believing that it generally acknowledges a constitutional cause.*

Our experience as to the absence of any parasite in the hairs is stated above. Dr. Jenner, in an excellent clinical lecture on the Diseases of the scalp having a parasitic origin, recently published in this Journal, includes in that class Alopecia circumscripta. He states, however, that he does so in deference to other writers (chiefly Continental), and avers that he has himself never once succeeded in finding the fungus in question. Now, supported as our own conclusion is by that of so careful an observer as Dr. Jenner, we are, we think, justified in asserting that the disease has no parasitic element. As far as we are aware, no English observer has ever been able to demonstrate it; and such is the confusion in the nomenclature of skin diseases on the Continent as well as here, that we cannot help suspecting that the cases in which German microscopists have noticed it, although styled by them by the same name, were not really cases which would have met our definition of Alopecia circumscripta. Very possibly they were cases of true ringworm in a stage much modified by treatment. M. Robin (a), adopting the statements of Gruby (b), has described two different fungi, the *Trychophyton tonsurans* and the *Microsporon Audouini*, as the causes respectively of *Tinea tonsurans* (true ringworm) and *Porrigio decalvans*, or, as he also terms it, *Alopecie idiopathique*. We believe that in English practice these two affections are but varieties of the same, and ought both of them to be classed as true ringworm (*Tinea tonsurans*). Whoever will read M. Gruby's description of them will at any rate feel certain that neither is the Alopecia circumscripta of this report. He describes (as rendered by Robin, page 428) the hairs as becoming brittle, breaking off, and leaving the affected portions of the scalp "d'un gris blanchâtre, à cause du cryptogame qui couvre ces surfaces." The great difference in the mode of attack between the two fungi is asserted by M. Gruby to be, that the one, *Trichoph. tons.*, develops itself only in the interior of the hair-bulbs, whilst the other, *Tric. Audouini*, eats into the hair-shaft after it has emerged from the scalp; yet the former only causes the hairs to break short off, whilst the latter makes them fall out—the very reverse of what might have been expected. The utter confusion of M. Robin's own ideas in the matter is evident from the fact that he endorses on one page the description of M. Gruby, who gives the exact measurement of the crust caused, and on the next that of M. Bazin, who asserts that the disease is "sans squames, sans croutes, sans décoloration des parties malades." The truth probably is, that whilst Bazin is describing the disease which is the subject of this report, Gruby was writing of a form of true ringworm. We need hardly point out that the proof we have afforded of the non-contagiousness of Alopecia circumscripta tends also to support the conclusion that it is non-parasitic. Most (but not all) phyto-parasitic affections are very contagious.

And now to turn to the evidence that the disease is one of constitutional origin. Out of the 42 cases in our series, the patients in 20 stated that they had experienced no indications of deranged health whatever prior to the occurrence of the baldness, and that they had also remained in good health during its advancement. In 10 instances a certain degree of languor had been noticed as a premonitory symptom, and in 6 there had been symptoms of indigestion. Eight had been getting thinner before the hair began to fall, and 4 had suffered from severe headaches. Two were just recovering from severe illnesses at the time. These statements are of course based upon the information given by the patients themselves as to their previous history. We have described the health at the time they first came under our notice as being in 13 cases excellent, in 15 good, in 8 moderate, in 2 the patients looked decidedly delicate, and in 2 a markedly cachectic state

B, healthy bulb.

A, wasted bulb.

(b) *Recherches sur la Nature et Développement du Porrigio decalvans en Phyto-alopœcia*. 1843.

existed. In 15 of the cases the patients appeared to have been well fed in every respect, in 9 moderately, and in 12 badly. We must leave these facts to the reader, as the best we have to offer. Although a considerable proportion of the patients showed one or other manifestation of disordered health, yet we must admit that in many they were as well as could have been wished, and that we are quite unable to connect this singular disease with any particular group of constitutional symptoms, or special form of cachexia. We do not recollect ever to have seen it in fat persons, and most of its subjects have certainly been lean beyond the average. Speaking from memory, we should have said that headache had been a common premonitory symptom, but our notes do not prove that it was so. It was certainly of very marked character in one or two of the cases, and had been particularly noticed by the patients themselves as a thing they were not accustomed to. M. Bazin, whose description of the disease is the fullest that we know, states only respecting constitutional symptoms, "Le malade éprouve parfois d'assez vives démangeaisons."

**PROPOSITION XII.**—*That it is not met with, however, sufficiently often in connexion with any particular group of constitutional symptoms to justify us in considering it as consequent on any peculiar form of cachexia.*

We have above discussed the evidence on this point at sufficient length.

**PROPOSITION XIII.**—*That it is occasionally liable to relapse after cure, but that the bald patches rarely show any disposition to change of place.*

All the facts respecting the tendency to relapse, to change its place, etc., are in close accordance with our assertion respecting its nature, namely, that it is not parasitic. Unlike those of ringworm, its patches rarely change the place on the scalp which they have once assumed (Case 22), and with the most extreme rarity is there seen any tendency for the hair to grow in the centre (Case 29). Usually the hair falls rather quickly, and bare surfaces having been produced, they either remain *in statu quo*, or gradually extend at their borders. From the junction of several patches a large, irregular, bald surface is often produced. It is not to be imagined probable, had the disease a cryptogamic origin, that it would ever get quite well for a time, and then, after a prolonged interval, rapidly relapse. Yet when once the reproduction of hair has commenced, it usually proceeds quickly, and on all the patches simultaneously, just as it ought, admitting the affection to be a constitutional one. In the case of William Blanshard (No. 2) we have seen that he had been liable to the disease for six years, but that out of that period he had been quite well for several successive ones. In that of George Smethwaite, aged 12 (Case 10), repeated relapses had taken place during a period of five years, the scalp having several times been well covered with hair. He had noticed that the hair usually fell in spring. This history is exactly that of a constitutional eruption such as eczema or psoriasis, but not at all that of favus, ringworm, or pityriasis versicolor. In Case 17, likewise, the boy had been cured at the Hospital two years before, and had remained well until within eight months of his second admission. The man who was the subject of Case 34 had likewise experienced a relapse after a complete cure. In Case 23 many relapses had occurred. With these exceptions, in almost the whole of the cases in our series, the disease had, up to the time of the note, either continued steadily to spread, or had remained at least without tendency to recovery.

**PROPOSITION XIV.**—*That it is of extremely chronic nature.*

To be convinced of this it is but necessary to run the eye down column 8 of the table. In almost all the disease had existed despite much treatment for many months, and in not a few its duration was measured by years. Thus in Case 5 it had existed three years; in Case 6, five years; in Case 10, five years; in Case 23, seven years; in Case 28, sixteen years; in Case 30, six years; and in Case 34, eight years.

#### TREATMENT AND PROGNOSIS.

We regret that we have not been able to add a column to the table of cases, stating in each the ultimate result, and the means of cure. This is owing to the great chronicity of the cases, and to the fact that most of the patients ceased attending as soon as improvement was well established. Mr. Startin's plan is to treat the disease by local stimulants, with constitutional alteratives, and tonics. Blistering the affected parts with Bullen's vesicating fluid was practised in all the

cases, usually at intervals of about a fortnight or three weeks for several months together. In all also a lotion, containing the tincture of cantharides, and some other irritants, was ordered for use when the blister had healed. A common formula was two ounces of the compound sulphur lotion, half an ounce of tincture of cantharides, and four of water. The mixture ordered for internal use usually contained small doses of bichloride and of arsenic. There does not appear any reason to place faith in mere tonics and good diet; alteratives, and remedies having specific influence over the cutaneous system, are evidently more requisite. Nearly all the patients had been under other treatment before coming to this Hospital, and many had taken cod-liver oil, tonics, etc., freely. Dorothy Quick, the patient in Case 22, had, for instance, been a whole year under treatment at the Children's Hospital, during five months of which she was an in-patient, having meat daily, and taking cod-liver oil, yet without, as her mother stated, any permanent benefit. We mention this merely as proof that liberal regimen will not always cure the disease. The case was a very obstinate one, and but little advantage was obtained while it remained under our observation.

The prognosis given in this troublesome affection may be fairly confident as to final result, but must be very cautious as to time. If the case have lasted already over several years, a much more guarded opinion must of course be offered; but even in these an ultimate recovery usually takes place. Those seen within a month or two of their origin, and treated by the blistering and alterative plan, usually get well in the course of a few months. The first appearance indicative of recovery is the growth of down over the patches, simultaneously with which the skin usually becomes thicker and more unctuous. The microscope is of the greatest use in arriving at an opinion as to the probable duration of the disease. If the hairs at the margins of the patches are found to have wasted bulbs, it is evident that the disease is spreading; whilst, on the contrary, if their bulbs are plump, and more especially if the bulbs of what down is found on the patches themselves are well developed, there is every hope of speedy improvement. The effect of blisters also furnishes another criterion. If very slight vesication is caused, but, on the contrary, much pain and irritation, the prognosis is much worse than if the blister rises well, since it indicates a more advanced state of atrophy of the integument. With the same view, the effect of scratching the bald patches should be tried. If a sharp scratch leaves only a whitish line, instead of causing a broadish streak of redness, it is evident that the vascularity, innervation, etc. of the part is very much below par.

JONATHAN HUTCHINSON.

#### POPLAR HOSPITAL.

##### COMPOUND FRACTURE OF THE SKULL WITH DEPRESSION.—OPERATION.—DEATH.

(Reported by Mr. BROWNFIELD, House Surgeon.)

Magnus —, aged 36, a seaman, tall and muscular, having fallen from his ship to the bottom of a dry dock, a distance of twenty feet, was brought to the Poplar Hospital, and admitted under the care of Mr. Webb, Jan. 5, 1858, 4 p.m.

He is profoundly insensible; pulse 60, small and weak; surface pale, cold, and wet, there having been a little water near to where he fell. Pupils act; breathing stertorous. There is a wound of the scalp on the anterior and lateral part of the left side of head, about four inches long crossing the coronal suture, and immediately beneath it can be felt a large piece of depressed bone, (about two square inches.) Mr. Webb, who saw the patient soon after his admission, determined to elevate the depressed portion immediately, to remove the pressure on the brain, and thus endeavour to relieve his most urgent symptom, the stertorous breathing. He, therefore, made another incision from the wound, which then represented an inverted  $\lambda$ , and by carefully dissecting forwards a little, laid bare the depressed portion and sufficient sound bone to pierce with the trephine, which was very carefully done, and then two triangular pieces elevated and removed, exposing a large clot of blood on the dura-mater. One piece of parietal bone, not wholly detached, was forcibly lifted into its place; the flaps were then adjusted and brought together with one suture, and the wound dressed with

MELANCHOLY PASSING INTO MANIA.

Engraved on Stone by W. Dugg

Printed by Tallman & Co.

water dressing. During the operation the patient did not evince the slightest sign of pain.

Ordered—Cal. c. jalap. ʒi. stat. sumend.; milk diet and beef tea.

7th, 3 a.m.—Breathing less stertorous; grunts when called to; lying quiet.

10 a.m.—Breathing quite natural; perfectly sensible; tells his name, where he belongs to, and answers any questions; and says he is quite free from pain; pulse 72, soft; tongue clean; skin cool and moist; wound looks well; has taken some bread and milk for breakfast; bowels not relieved, nor has he passed any water. Hyd. chlorid. gr. v. stat. sumend; Mist. salin. cath. 6tis horis, ʒi.

8 p.m.—Is rolling about in bed uneasily, but states quite free from pain; no symptoms of hemiplegia; passed urine, smelling very strongly; pulse 108, small. Haust. aperiens, stat. sumend.

January 8, 10 a.m.—Bowels freely relieved during the night, and he is now sleepy, answering questions, and then goes off again to sleep; pulse 100, soft and small; skin rather hotter; tongue clean; wound healing by the first intention, except the top, where it is opened a little.

10 p.m.—Has become much more restless, the last hour rolling about, passing his hands frequently up to his head; complains now of pain there, and talks about his ship.

9th, 10 a.m.—Not so restless, nor does he complain of so much pain this morning; quite sensible; not so sleepy; takes his food well; passed a large quantity of urine through the night; pulse 80, full; tongue coated with a thick whitish brown fur, but moist.

10th.—Much the same. Pulse 84.

11th.—Passed a restless night, and is now very uneasy. Wound more opened; discharge unhealthy, bloody, and offensive; head hot. Pulse 92, small. Haust. domest. ʒi. stat.

10 p.m.—Is now more quiet; has taken milk and bread only through the day.

12th.—Not so well. Signs of hemiplegia begin to manifest themselves this morning in the right arm and leg. Is not nearly so sensible; will not put out his tongue. Pulse 80, soft and small. Skin covered with perspiration; scalp puffy; bowels not relieved; respiration quickened.

10 p.m.—Scalp and right side of face swollen. Matter evidently burrowing. Made an opening into the most depending part of the scalp, and let out about ʒi. of very offensive pus. Respiration more quickened, and complete paralysis of the whole right side. C. c. j. gr. x. stat.

13th.—Lying perfectly helpless, and insensible to everything. Skin covered with a profuse offensive perspiration. Pulse 120, very small and weak; respiration 16. Discharge from wound abundant and unhealthy; scalp hotter; bowels not relieved. Enema tereb. stat.

This not relieving the bowels, ordered—Ol. croton. ʒj., lin. sapon. ʒj.: ft. lin. abdom. perfic.; dec. cinchon. ʒj., acid. sulph. dil. m.v.; ʒi. 6tis horis.

2 p.m.—Sinking fast; covered with a profuse and very offensive perspiration. Pulse very small, and so frequent that I cannot count it. Eye peculiarly bright; respiration hurried, short, and feeble; and in this state he continued till 4 p.m., when he expired.

No post-mortem.

## HOSPITAL NOTES.

### TREATMENT OF APHONIA BY ELECTRICITY.

A case of aphonia was observed at the Samaritan Free Hospital, under the care of Dr. Savage. A woman, aged 21, lost her voice a month ago; she thought it was brought on by her having caught a cold. The movements of the tongue were not in the least impaired. There were no signs of inflammation nor of ulceration of the larynx; very little cough, and some little pain in the larynx, as well as in the chest. No tubercular deposits in the lungs. She has always been regular. Purposely no medicine was given, but Dr. Savage asked Dr. Althaus to try what Faradisation might do for her. Dr. Althaus applied the current of the first order of his apparatus of induction by means of solid metallic excitors covered with wet fingers of gloves, localising the electric stimulus in the inferior laryngeal nerve, which animates all the muscles

of the larynx concurring to the formation of the voice. The day after the first sitting, which only lasted two minutes, the speech seemed to be not materially improved; but in the course of whispering sometimes the normal sound of voice returned. After the second sitting of the same duration as above, the improvement was striking; the day after the third *séance* the patient spoke almost quite naturally, and the treatment was discontinued after another sitting, as now the speech is going on perfectly well. We know of no other case of aphonia in which the effect of the electric treatment was so quick and manifest, without having been connected with any inconvenience whatever. Professor Sédillot applied electricity in a case of aphonia, one pole being placed alternately on different parts of the tongue, and the other one on the mastoid bone, the posterior and superior part of the neck and various points of the face. The application was useful, but could not be repeated until one week afterwards owing to severe headache, which had followed the application of electricity. By localising the electric stimulus in the inferior laryngeal nerve no such inconveniences were produced.

### INJECTION OF THE KNEE-JOINT WITH TINCTURE OF IODINE.

Mr. Erichsen adopted, in a case of chronic effusion into the knee-joint, under his care in University College Hospital, a few months ago, the treatment by injection of iodine. Although so highly praised by Velpeau and other French surgeons, this practice has not hitherto found many English Medical men bold enough to pursue it. Mr. Callaway, of Guy's, we know entertained, from what he had seen of it in Paris, a very favourable opinion of its merits; but he did not, we believe, ever actually do it. Mr. Erichsen's patient was very well suited for it, the hydrarthrosis having existed for a considerable period, and the general health being good. Much treatment had also been previously adopted, with only very transient benefit. The injection was performed on December 2, about six ounces of amber-coloured fluid having been previously withdrawn by the canula. Only a drachm of the compound tincture was thrown in, but the whole of it was allowed to remain. A certain degree of pain, etc., was present in the joint for about a week afterwards, but it was not at any time excessive. The man left the Hospital, very much benefited, six weeks after the injection.

### NEW INSTRUMENT.

### RUSSELL'S ELASTIC TRUSS.

This instrument, made by Mr. Russell, of Orchard-street, consists of a powerful elastic band, three inches deep, superseding the ordinary steel spring—an inflated pad—and an elastic understrap, as illustrated in the above engraving. By slight modifications it is adapted to inguinal, femoral, or scrotal hernia. It is a fact familiar to all who have had experience in the treatment of hernia, that while it is comparatively easy in most cases to obtain a truss that will prevent the protrusion of the viscera, it often proves very difficult to obtain one that can be worn without discomfort; consequently, many persons have put aside trusses and gone without rather than suffer the pain or annoyance they occasion. Mr. Russell states that the elastic truss above described is particularly adapted to cases of this class, and that it has been used in many such cases with the most satisfactory results.

## PROSTITUTION.

## THE VISIONS OF PHILANTHROPY.

THERE is nothing like letting enthusiastic philanthropists have their full swing at talking. They are certain before they finish their oration to furnish weapons for their own annihilation. The *reductio ad absurdum* is sure to crop out at some point or other of their argumentation. Such gentlemen spoil the very best of grievances, through their unfortunate manner of handling it. And this is just what some of them are now endeavouring to do in the matter of Prostitution. The subject is of course one upon which eloquence may disport itself with great satisfaction, about which indignation may effectively proclaim its justly excited anger, and pity breathe forth its gentle suppliant notes. And all this is very desirable and very good. Every one is most anxious to see the miseries of the world expelled from it, but unfortunately the enthusiast does not stop here. He is not contented with merely arousing the emotions of his auditory. He wants to do more than excite men to deeds of goodness. He would show them *how* to be good, and here it is that he so often consummates a failure. The listening crowd is delighted with his theoretical eloquence; but the moment he descends from the empyreal region of imaginary philanthropy into the beaten track of common sense, his wings fall off and down he comes, a sorry spectacle, shriveled up, like that unfortunate Icarus of old.

This is surely the case with some of the writers who have been trying their hand at tinkering up Prostitution. They have attacked the authorities right and left for their gross supineness, for their *laissez-faire* of the vice; and then, in order to leave the careless powers without excuse, they tell them what there is to do and how to do it. And their advice is the very justification of do-nothingism; its utter absurdity, without a word of refutation, becomes patent at once to every living soul except the concoctors of it. And then Authority sits placid, and smilingly suggests: "Now, really, gentlemen, if this is the only scheme your deep knowledge of the subject enables you to elaborate and propose for our acceptance, you have been sadly wasting your time and much fine eloquence; if this is the only remedy you can invent, you must excuse me for saying that I do not think there is much left for authority to do which it has not already done in this matter."

Let us now consider for a moment, as illustrative of the above remarks, one or two of the schemes for the suppression of the vice which have been propounded by the high apostles of philanthropy in reference to Prostitution.

One of our contemporaries has pleaded eloquently in the good cause where Virtue and Pity are pitted against Vice and Hard-heartedness, and all goes well with him until he comes to the most interesting point in his discourse, and lets out the nature of his succedaneum for the cure of the distemper.

When this is out, then, indeed, it is sad to see how he comes down with a run, as T. P. Cooke would say, from his sublime position!

"It now remains that we briefly indicate the plan which seems most fitted to cope with the evil in its every stage, with its causes and its effects. We propose that there shall be established in London a Board of Moral Health, whose object shall be the control, either directly or through local authorities, of all evils which are injurious to society, either by their existence, or by the excess to which they are carried." The moral duties of the Board, by the way, are here put rather in imbroglia: we would just remind the writer that an evil could not be an evil or anything else unless it had an existence, and that all evils which have an existence are injurious to society; evils, also, are *always* in excess, though some of them are excessively great. But to return. The duties of the Board, as thus defined, are tolerably extensive. "All evils which injure society." This is, indeed, a Board wherewith the most swelling breast of philanthropy may dilate without fear of exhausting its sympathies.

Its powers are to be unlimited. "Whatever is injurious to the moral welfare of society," one stroke of its pen shall instantly remove. So that if, by accident, Puritanism presided over its councils, at one stroke of the said pen down would go Drury Lane, Willis' Rooms, Epsom's gay Derby-day, Robson, Buckstone, and Punch, and every other exciter of merriment and laughter! Our Venuses and Erolo Farneses would have to put on chemises and inexpressibles! Milliners would have to learn from authority how high below and how low above their draperies were to mount and descend in accordance with "the moral welfare of society." But we would more particularly point to the Board's efficacy as controlling prostitution. And under this head our literary brother relates a variety of nuisances, which he would quickly have shoved out of the way. Now he will be greatly gratified to hear, that at this present moment, as regards the items he specifies, the police have all the requisite power to abate the nuisances. Our philanthropic schemer has evidently not studied the Metropolitan Police Act, or we should not have had occasion to tell him this. We cannot say anything about the "thousand things like them" which foment the evil, and which he tells us might be readily repressed, because we are not told what they are.

But this Board is to be more than a mere repressor and punisher. It shall not only put down "the harlot who solicits and takes possession of the *παρῆς*," but it shall also be a House of Call, where the outcast may make her appeal. It shall be a positive reformatory for our modern Magdalenes!

Let us see, again, what another philanthropist has to say on the matter—one, who as author, and orator, and healer, has made his name conspicuous in the modern annals of Prostitution. He has well studied the question in all its evil bearings, moral and physical, and will help us in our difficulties. His writings, moreover, as we see from the daily advertisements, have received the imprimatur and approbation of my Lord-ex-Chancellor Brougham. Here, at all events, we shall find good precepts to guide us to sensible views of this dark side of human nature. We have already reviewed the book, and found many a good old truth well told, and excellent advice in general administered. But the special succedaneum: Our readers shall hear it.

Special police, with powers of domiciliary visitation, or, in other words, legalization of Prostitution. We have already demonstrated the immorality and inutility of such a proceeding, and its utter incompatibility with the free spirit of this country's laws. Our author has, we fear, got rid of some of the more respectable of our insular prejudices—a love for liberty of the subject, for example—whilst imbibing a knowledge of his speciality as a Parisian Externe. Together with the science of his particular branch of the craft, he seems to have

acquired in foreign parts an admiration for Bureaucratic Autocracy, Sergens de ville, Inscriptions, and the perfected paraphernalia of Red Tapism. For instance, if Prostitution too flauntingly proclaims itself in open day in the midst of respectable fashion, he gives us a remedy, which never could have been invented in an English brain. Lay on "a service of constables, numerous, and not secret, but flagrant in their uniforms." Let them "follow industriously the *troupe* complained of up and down, until they (the *troupe*) extend their radius from 200 yards to two miles. I am convinced they would be soon starved into capitulation, because no customer at all likely to be profitable would accost them under such surveillance."

Now, in the name of common sense, how can we wonder if responsible legislators show a cold shoulder to the eagerness of gentlemen whose propositions involve such scheming as this, who would regulate prostitution by a system of low bullying and trickery worthy only of the lowest mouchards attached to the service of Sig. Pietri, Chef de Police de S. M. l'Empereur Napoleon III. We really, as public monitors, feel bound to hold up before the light these dreamy phantoms of philanthropic minds, that our readers may view their poor and threadbare character. Infinite mischief is done to the best of causes by the indiscretion of its supporters. Its warmest friends are thus often its worst enemies; when they seek for sympathy, they only bring down ridicule upon it.

Such, then, being the police supervision recommended by our author, let us look at one or two of his sanitary arrangements, and see if he is more successful. Syphilis being an infectious disease, demands unusual facilities for its cure; and our Hospital accommodation runs disgracefully short. Let us, therefore, he says, establish a "London Female Sanitary Society,"—a benefit-club for prostitutes. "Lay and professional persons of good repute" shall manage it, but district doctors are to be the mainstays of the work. They are to be the visiting agents in the scheme, bringing healing in the one hand, and moral good tidings in the other. All the machinery of this plan of course we cannot display, but we will give a sample or two of its nature:—"One of the most important of his duties in connexion with the Society would be the inculcation of prophylactics upon women in health." . . . "The value, proper times, and proper method of ablution should be first dwelt upon." "Most scrupulous use of soap and water immediately after connexion should be insisted upon, and micturition at the same time;" daily injections "of one ounce of solution of chlorinated soda to one pint of water, applied with a proper elastic syringe, the ordinary pewter ones being of little use." But we must stop, for our pen hesitates in describing these details of the "most important duties" of our sanitary confrères.

We have surely said enough. Principles which lead to such practices as these bear with them their own condemnation. Does the author of the scheme really believe that he will ever find a body of Medical men who will assist him in carrying out such things as these? Does he really think that he is diminishing vice by the fostering of such a system as this?

We feel compelled to ask attention to what we cannot help calling these aberrations of philanthropic intelligence; because we see how ridiculous they make us in the eyes of a moral, a common-sense, and practical community; and because the ridicule unfortunately involves alike, and so renders impotent, that which might be done effectively towards diminishing the evils of Prostitution, and assisting the victims of it to rise from their low and degraded estate.

#### THE WEEK.

THE following General Order, just issued from the Horse Guards, is one of the first-fruits of the labours of the Royal

Commissioners on the Sanitary Condition of the Army. It gives to the Medical officers the substantive rank they have so long demanded in vain:—

"His Royal Highness the General Commanding-in-Chief directs that when officers of the regimental staff or of the civil departments are called upon to attend as members of courts-martial, courts of inquiry, and boards of investigation or survey, they shall sit and vote by seniority according to their relative rank, as set forth in pages 6 and 7 of the 'Queen's Regulations' and Orders for the Army, except as presidents, which post will always be filled by the senior commanding officer."

"By command,  
"G. A. WITHERALL, Adjutant-General."

In a minute upon the reformation of the Indian army Medical service, written shortly before leaving India, the late Governor-General Lord Dalhousie makes the following remarks upon the most unmeaning and purposeless regulation, by which a sense of inferiority was imposed upon Medical officers, by the refusal to them of substantive rank.

"The surgeon and assistant-surgeon rank invariably with the captain and lieutenant, but the rank is only nominal wherever medical officers and others are brought together on public duty; the former has no rank at all, and the oldest surgeon on the list must, in such case, range himself below the youngest ensign last posted to a corps. It is impossible to conceive how such a system as this can have been maintained so long, on the strength of no better argument than that 'it has been,' therefore 'it ought to be.' It is impossible to imagine what serious justification can be offered for a system which in respect of external position postpones service to inexperience, cunning to ignorance, age to youth; a system which gives a subaltern who is hardly free from his drill precedence over his elder, who, perhaps, has served through every campaign for thirty years; a system which treats a member of a learned profession, a man of ability, skill, and experience, as inferior in position to a cornet of cavalry just entering on the study of the pay and audit regulations; a system, in fine, which thrusts down grey-headed veterans below beardless boys."

What Lord Dalhousie did for the Indian Medical Service, the Royal Commissioners have done for the Army. Army Medical officers have now the substantive rank so long denied them, and one of the most galling regulations as to their position is removed. The result upon the service must be most beneficial.

The *Morning Post* takes a curious view of the late appointment of Mr. Charles Hawkins as Inspector of Anatomy. In a leading article it is said:—

"We did not know anything for or against this gentleman, till, upon making inquiry in several quarters, we received the uniform reply that he is generally recommended by Sir Benjamin Brodie, an eminent surgeon, intimately acquainted with the Anatomy Act difficulties under the Somervillian reign. This is, doubtless, a good recommendation of Mr. Charles Hawkins, but it is not good enough to obliterate the history of his appointment as unfolded in the Medical Journals. He is, we are there told, appointed at the unanimous request of the anatomical teachers, and for their purposes. This, as a sequel to the disclosures regarding the transactions between Guy's Anatomical School and Newington Workhouse, is really too bad. How is it possible for Mr. Charles Hawkins, under such circumstances, to have the prestige of independence, without which the difficulties of a difficult office will be increased a thousandfold? The idea of the anatomists appointing the Government officer whose duty it is to inspect their establishments and watch their conduct is highly original. We may next expect to hear of landlords surrendering the nomination of their gamekeepers to the poachers of their neighbourhoods; or (to take a still more applicable example) of Government allowing each distiller to nominate the Exciseman to visit his premises for the purpose of checking infringements of the law."

Then follow quotations from our pages to prove that the teachers really made the appointment; and the article concludes thus:—

"It is very natural for the teachers to wish for a good purveyor, but the statute contemplates the appointment of an impartial inspector. Such an officer is urgently required. Under cover of the present very imperfect Anatomy Act it has been seen that great misdemeanours have been committed and connived at by officials. Our firm conviction is, that from the high price to which the undertakers have been allowed to raise bodies, there arise at the present moment dangerous temptations to much worse crimes than have yet been revealed. In former articles we have shown that the interests of science—which are truly the interests of humanity—and the cause of social order, imperatively demand that the law should be so amended as to reduce the commercial value of a dead body to zero. This reform might easily be accomplished; but our fear is that Parliament will not interfere till the schools are deserted from being without supplies, or till the public mind is shocked with the disclosure of horrible crimes."

Putting aside, as unworthy of reply, the insinuation that the teachers have any other object in view than the public good, we are very glad to see our own arguments as to the necessity of lowering the price of subjects so ably reproduced by our political contemporary.

The report of the Annual Meeting of the Medico-Chirurgical Society on Monday will be found in another column. Sir Charles Locock's address was earnest and effective, and his biographical notice of deceased Fellows, though brief, evinced intimate knowledge of, or careful inquiry into, the characters of our departed brethren. This part of the address will appear at length in the "Proceedings." The other portions will be found in our report.

The following extract from Dr. Gibbon's last weekly Report on the Sanitary Condition of the Holborn District, alludes to a fact which may not have been generally observed, but which may be observed, *if looked for*, in all badly-sewered streets.

"My attention has been called to the blackening of the newly-painted doors and houses in some of the streets of the district, especially in Hatton-garden. There can be no doubt that such discoloration is effected by the action of sulphuretted hydrogen gas on the lead paint, forming a sulphide of lead. This sulphuretted hydrogen gas escapes from the untrapped gullyholes of the sewers. When it is emitted in such large quantities, it is a clear indication that the sewers are defective in their construction, and therefore do not properly perform their office, which is to carry off not to contain decaying animal matter, and vegetable refuse."

Dr. Olympios, a Greek physician, has just made known a curious fact relating to the history of lithotripsy, showing that this operation was practised as early as the commencement of the ninth century. It appears that a certain Theophanes, once a monk, now a saint of the Greek Church, wrote under the title of "Chronography" a work which has since formed part of a collection of the works of Byzantine historians. The biography of Theophanes, by a contemporary Greek author, is prefixed to his work, and in this biography Dr. Olympios has found a remarkable passage. It is preceded by an account of the Emperor Leon the Armenian sending for Theophanes, "not by employing tyranny and violence, but attracting him by customary caresses and flatteries." Then it goes on, as will be seen by reference to the original which we quote below, to state that Theophanes reflected upon the habitual bad temper of the emperor, and seeing that he was tormented by dysuria and chronic disease of the kidneys, introduced instruments into the bladder by the natural passage, and after having crushed the stones, extracted them, and permitted the urine to flow as freely as possible. The emperor, although he kept his bed, then embarked for the capital. It should be noticed that the word *διαβρίσκοντα*, which we have rendered by *crush* (as has been well observed by Dr. René Brian, in the

*Gazette Hebdomadaire*), leads to the suggestion that the terms lithotripsy or lithotripsy are etymologically incorrect. The Greek word *τριβω* signifies, I rub, or rub away, while *θρόνω*, the verb used in the text, expresses the exact action of the crushing instruments. Thus, *lithothripsis* would be the true orthography, and this is that adopted by the modern Greeks. We merely allude to this as interesting to scholars, not with any wish to supersede the well-understood term lithotripsy. We now append the text:—

Ὁ δὲ (Θεοφάνης) τὸ τῶν τῶν κακὸν ἐπιστάμενος νεφρῶ πολυχρονίῃ καὶ δυσουρίᾳ τρυχόμενος· ὄργισα γὰρ διὰ τοῦ φυσικοῦ ὁνομήνῃ τῇ κύστῃ παραπεμπόμενος καὶ τοὺς ἐγκειμένους ἐν ταύτῃ διαβρίσκοντα λίθους τοῖς ἐκτὸς παρεπέμποντο, τὴν ἔξοδον τῇ ὑγρῇ περιττώματι, ὡς δυνατόν, ἀκόλυτον μηχανώμενα. Τοῖς οὖν τρυχόμενος καὶ κλιθήρης διὰ βίον ὑπάρχων, ἀκατίῃ περαιωθεὶς πρὸς τὴν βασιλίδαν πόλιν ἐγκαταβρίσκεται.

If the following statement in the *North American Medical-Chirurgical Review* be a correct representation of the facts in respect to the Jenner monument, it must be admitted that it is very humiliating to our country as the birthplace of this great benefactor of mankind:—"It will be remembered that several years ago subscriptions were made in this country for the purpose of erecting a monument to Jenner, the illustrious discoverer of vaccination. The history of the accumulation of funds wherewith to defray the expenses of this merited tribute is interesting to us as Americans. When it was proposed in England to erect a monument to this distinguished physician and philanthropist, it was suggested that, as it might be an object of universal interest, the people of all nations would gladly contribute. Aid was accordingly solicited from the United States, and the appeal was so much more cordially responded to in this country than in the one in which the movement originated, that it may be truly said that the Jenner monument in London is essentially an American tribute, which the English people have assisted in paying, to an English celebrity. Of the whole sum collected some time ago \$340 were transmitted from America—£112 from the Philadelphia Committee; while, in the country of his birth but \$196, including \$26 from the Prince-Consort, were subscribed."

A card, of which we now give an exact copy, has been forwarded to us from Liverpool this week:—

"PRIVATE MEDICAL ADVICE.

DR. EVERED, F.R.C.S.

Physician to the Portland Dispensary,  
17, UPPER PITT-STREET,

Two doors below Great George-square, Liverpool.  
Continues to be consulted on all cases of a private nature, comprising Gonorrhœa, Gleet, Strictures, Eruptions on the Body, Bubo, Secondary Symptoms, etc., and guarantees a perfect cure of slight cases in two or three days without the use of Mercury or hindrance from business. Those who are labouring under the effects of Early Excesses, causing Incapacity, Impotency, Trembling of the hands, Emissions during Sleep, Weakness in the Loins, Loss of Memory, Pimples on the Face, Depression of Spirits, Involuntary Blushing, Incapacity for Study or Business, Confusion, Dislike of Society, Giddiness, Fulness after Meals, Noises in the Head or Ears, should immediately apply for relief, as Dr. Evered's successful treatment is based on thirty-five years practical experience, which is a sufficient guarantee for his promptitude and skill.

Extract from the *Medical Times*, July 26, 1856.—"We should advise those of our medical friends who have serious, or what may be considered incurable, cases of the Venereal Disease to hand them over to Dr. Evered, as in no instance do they leave his treatment without a perfect Cure being effected."

The utmost secrecy may be relied on. Consulting hours from nine in the morning till nine in the evening. On Sundays till three o'clock.

Observe.—17, Upper Pitt-street, two doors below Great George-square."

It must be quite unnecessary for us to inform our readers that the pretended extract from our pages is an impudent forgery. Surely some amendment in the law is necessary to render punishment easy and severe in cases of such deceit practised on the public.

When Mr. Urquhart was lecturing last year in London on the Turkish bath, and endeavouring to teach the British people that 140° of Fahrenheit was the proper temperature for a warm bath, and that baths of this temperature might be taken with impunity, we ventured to hint that a layman was not the most fit apostle of hygiene, and that very sad results would probably follow should Mr. Urquhart's advice be generally adopted. We little thought that his own child would be one of the first sufferers under his system; yet his son, thirteen months old, has died, and a coroner's jury, while returning a verdict "that the evidence is unsatisfactory as to the cause of death," highly censured the treatment of the deceased. This treatment is thus described by a servant:—"Mr. Urquhart has a bath or room at River-side, heated with pipes, in which the deceased has been put, the temperature being from 100° to 140°. He has been in this bath some days as much as six or seven hours, being taken out at times to cool. Sometimes he had cold water poured on his head, and sometimes put under the pump and pumped on, which he seemed to enjoy. Sometimes he was laid out on the verandah on his cot-bed. He generally had on a light dress, which was the only clothes he was allowed to wear." Mr. Codd, the surgeon who made a post-mortem examination, deposed: "On the surface and cavity of the brain there was a quantity of serum, otherwise the brain was in a healthy state. This was of very recent date. The stomach was very healthy, and nearly full of food. I attributed the death to congestion of the brain, but I do not know how brought on. I cannot say if brought on by the treatment described. I consider the treatment might bring on congestion of the brain." This treatment of a feeble child by a combination of hot vapour baths and scanty clothing in an English winter certainly shows the extraordinary tenacity of life in our species, but we trust it will also teach the lesson so much needed just now to avoid the dangerous quackeries of half-educated enthusiasts, and to trust in all matters of life and health to those who can give some guarantee of their knowledge of the laws of physiology and pathology.

## REVIEWS.

*The Medical and Legal Relations of Madness; showing a Cellular Theory of Mind and of Nerve-force, and also of a Vegetative Vital-force.* By JOSHUA BURGESS, M.D. Pp. 283. London: 1858.

It is often far more easy to write a long book than a short one; because in the former case the author puts down at once all that comes into his own head, as well as much that is extracted from the works of others, without discrimination or selection; while in the latter case he weighs in his mind what he ought to insert and what to reject, whether of his own thoughts or the thoughts of other people. Now, although Dr. Burgess's book is not a very long one, we cannot avoid coming to the conclusion that he has adopted the easier alternative of giving us the somewhat crude outpourings of his own ideas, with very copious, and not always very apposite, quotations from the works of others. Although this tendency is very manifest in the whole of Dr. Burgess's volume, it is most especially remarkable in the section devoted to the treatment of Madness; for out of sixty-two pages appropriated to this part of the subject, no less than forty-five are filled with matters which have no relation at all to the therapeutics of insanity—such as the nature of physical and chemical forces, the treatment of cholera and typhus fever, the epidemics of the middle ages, miasm and hypermiasm, the siege of Sebastopol, the medical hypotheses of Cullen and Stahl, and a

multitude of other heterogeneous subjects, thrown together almost at random. The other seventeen pages contain all that the author has to tell us of the treatment of mental disorders, and this really does not amount to much; the chief novelties which have struck us being the recommendation of *the cobweb of the black spider* as an excellent sedative, and the laudation of good home-brewed ale combined with spices. As for the rest, insanity is considered as being generally a disease characterised by irritation and depression, and therefore to be combated by tonic and sedative treatment, together with such moral management and mild physical restraint as are practised at our modern asylums for the insane.

The cellular theory of mind and of nerve-force is expressed by Dr. Burgess in terms somewhat similar to the following:—The *apparatus or source of mental power* resides in the vesicular cells of the nerve-matrix. These cells are passive or dormant in early life, until they are excited by the senses, but the more the senses become used, the more ideas are generated, and the apparatus or source of power becomes increased both in volume and development, the more it is exercised and excited by the senses, and the force will be proportionate to the ratio of the excitants, which are the senses and ideas, and to the number and volume of the vesicular cells. The *conductors of mental power* are the medullary bundles of filamentous, or fibro-cellular tubes, ganglia or medullary coils; and the *excitants of mental power* are the senses and ideas which are derived from the impression of external objects. The senses commence the circle at one extremity of the fibro-filamentous tubes, which becoming impelled or passed through the vesicular cells, ideas are originated, and the circuit is completed at the other end by induction of will, memory, and understanding, in the cerebral mass or nerve-matrix.

After this exposition of the theory of mind, which, though ingeniously devised, is not very logically or clearly explained by the author, we come next to the pathology of the mind, or, in other words, to its morbid manifestations. Here we find a pretty good classification of the different forms of insanity, together with the details of several cases more or less illustrative of the principles and theories laid down; but we fail to discover any direct connexion between the cellular theory of mind and of nerve-force and the pathology of insanity. We gather, however, that Dr. Burgess agrees with Müller in considering the brain to act as a whole, although we are unable to determine the laws by which the different parts of the organ participate in the affections of each other; the results of pathological anatomy being often at variance with the phenomena presented by the living.

Some portion of Dr. Burgess's work is devoted to the exposition of the varying and often conflicting definitions of insanity and delusions, delivered at different periods by some of our greatest legal luminaries, as for instance, Hale, Lyttleton, Coke, Blackstone, Mansfield, Erskine, and, in later times, Lyndhurst, Brougham and Pollock; but these diversities of opinion are not to be wondered at, when we consider that however acute the mental powers of certain distinguished lawyers may be, they have no especial training in psychology.

*On Cough: its Causes, Varieties, and Treatment; with some Practical Remarks on the Use of the Stethoscope as an aid to Diagnosis.* By ROBERT HUNTER SEMPLE, M.D. Pp. 174. London: 1858.

To write well on a symptom of disease is more difficult than may be supposed. More especially is this the case when that symptom is common to a great number of pathological conditions. Dr. Semple, taking cough as his text, has traced it in connexion with the various affections of which it forms part, describing its various forms, its diagnostic value, and its appropriate treatment. In this we are bound to admit that our author has acquitted himself well. No speculative views are introduced, and in the style itself there is an earnestness which bespeaks attention.

Dr. Semple does battle valiantly with the Homœopaths, and his own practice is certainly anything but homœopathic. Speaking of the treatment of laryngitis, he says, p. 53:—

"I cannot help denouncing, with all the force which I possess, the inefficiency, and, I might add, the knavery of the so-called homœopathic system, in the management of such a disease as acute laryngitis, in which it may be said, 'Horrè

momento aut cita mors venit, aut victoria laeta, and in which the delay of efficient measures may entail the worst results.

"To mock the sufferings of a dying patient by the administration of inert and useless globules, while the adoption of a rational and vigorous plan of treatment might restore him to life, appears to me to be nothing less than to ridicule human misery, and to welcome the approach of the angel of death. I can only hope that if any honest homœopath (if there be such a person) should meet with a case of acute laryngitis, he would at least for the occasion renounce his creed, and prefer the sacrifice of a dogma to the destruction of a fellow-creature.

"Nor can I omit to observe, that I by no means coincide in the views of those who believe that, because diseases in the present day have changed their type, and because bleeding is not generally so well borne as it was formerly, *therefore* all bleeding and all depletion are injurious. I believe, on the contrary, that in certain cases the abstraction of blood is not only justifiable, but is imperatively demanded, and I believe that acute laryngitis is a case in point."

We find the following spoken of as the remedies in croup, p. 70:—

"After mentioning *tartar emetic*, *bloodletting* and *calomel* in the treatment of croup, there is not much more to be written on the subject; because these three powerful instruments in the hands of the Medical practitioner are sufficient to control the disease. The use of the warm bath, however, in the early stages may be recommended, as tending to divert vascular fulness to the extremities from the interior; and when the acute symptoms have subsided, the application of blisters to the upper part of the chest, or to the nape of the neck, *but not to the throat*, may be recommended."

There is another treatment not mentioned by the author, originally recommended by Dr. Lehman, highly praised by Graves, and one in which we have considerable faith in the first stage of the disease. It consists in the application of hot water to the throat, by means of a sponge squeezed half dry, and repeatedly applied, until a vivid redness of the skin is produced—the heat appears to be of much service topically—while a general perspiration, usually attended with amelioration of all the symptoms, occurs.

Although we have quoted Dr. Semple's views on the treatment of laryngitis and croup, as a specimen of the anti-phlogistic course which he advises in those diseases, we find that his remarks on blood-letting in other affections are particularly cautious, and even in pleurisy and pneumonia the abstraction of blood is recommended only in special circumstances and in the absence of diathetic complications. In all the convulsive diseases giving rise to cough he strongly denounces blood-letting and all other depletory measures. In laryngismus stridulus, for example, which may be, and often has been, mistaken for croup, he says:—"I cannot too strongly denounce the application of leeches, or any other measure having a lowering tendency;" and in the case of hooping-cough, "in the first place, it should be remarked, that as hooping-cough is not an inflammation it is useless, or worse than useless, to employ active depletory measures, either by blood-letting or purging."

We might take exception that the author has not dwelt on the diathesis productive of cough. There is a cough not alluded to, but which we have often met with. It seems to depend on the plethoric habit, associated with laxity of fibre. It is unattended by physical signs, and is peculiarly obstinate as regards treatment, but the mineral acids appear to be useful.

We repeat, in conclusion, that Dr. Semple's work will be found practical and useful, and as such we recommend it.

*The Principles and Practice of Obstetrics; including the Treatment of Chronic Inflammation of the Uterus considered as a frequent Cause of Abortion.* By HENRY MILLER, M.D. Professor of Obstetric Medicine in the Medical Department of the University of Louisville. Philadelphia: 1858.

"Of making many books there is no end."—Surely Dr. Miller might have found among the numerous text-books on Midwifery some one suitable to his alumni at Louisville. His book, as a class-book, is in many respects commendable, but in our judgment it most certainly was not wanted. One point upon which he insists, however, deserves attention—the alleged frequency of inflammation and ulceration of the "neck and body" of the uterus during pregnancy, which Dr. Miller says

he is persuaded "is among the most frequent causes of abortion;" thus supporting the views and practice made known here by Dr. Bennet.

*On Dislocations and Fractures.* By JOSEPH MACLISE, F.R.C.S. Fasciculus II. London: 1858.

Fractures of the ribs, humerus and clavicle, are represented in the four plates of this second fasciculus. They completely fulfil the expectations raised by the first, and justify the hope that the work will be a most successful one.

*Projectile Weapons of War and Explosive Compounds.* By J. SCOFFERN, M.B. Third Edition, revised. Pp. 306. London: 1858.

THIS work appears to have had considerable success, and to have attracted the attention of many persons connected with military affairs. The author tells us in one of his Prefaces that the brochure constituting the first edition was bought up wholesale by the agent of a foreign power. It is an amusing and readable book, and will no doubt prove useful to all military men, for whom, no doubt, it is chiefly intended; but civilians, to which class Dr. Scoffern himself belongs, will find much interesting information upon a subject which, in these warlike times forces itself upon the minds of the whole community.

*An Introduction to Practical Chemistry, including Analysis.* By JOHN E. BOYMAN, F.C.S., late Professor of Practical Chemistry in King's College, London. Edited by CHARLES L. BLOXHAM, Professor of Practical Chemistry in King's College, London. Third Edition. Pp. 288. London: 1853.

WE have on former occasions expressed our approbation of this useful work, and we find that it has lost none of its value under the hands of its present editor. It is exceedingly well calculated for the use of students, as the language is very perspicuous, and is rendered still more so by the introduction of a great number of well-executed wood-engravings, representing many of the ordinary operations of Chemistry and the apparatus employed.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON THE ARCUS SENILIS.

By M. CASTORINI.

M. Castorini, in a paper communicated to the Académie des Sciences, states that his experiments and researches upon the subject lead him to the conclusions:—1. That the arcus senilis is the result of an immediate imbibition of the circumference of the cornea by the more or less abundant secretions of the conjunctiva. 2. That the more or less permanent contact of the eyelids with the cornea is an indispensable condition of this imbibition. 3. That the process of imbibition is in inverse proportion to the resistance of the cornea and the density of the secreted fluids.

After detailing some of the experiments he has made in illustration of these points, he passes on to the arcus senilis as observed in man, remarking that aged persons combine the three conditions favourable to its production, viz., an increase of the conjunctival secretion, a less moveability of the eyelids, and a diminution of the resistance of the cornea. Every body must have observed that the secretions are increased as age advances. The eyelids also are contracted and less moveable. So also the fat of the orbit becomes absorbed, and the globe recedes; the eyelids being more closely applied to the eye, and covering the cornea more than ordinary, especially at its upper part. The arcus is oftenest found at the upper part of the cornea, because the corresponding eyelid being larger keeps this part constantly covered, and protected from evaporation. The form of the arcus is that of the edge of the eyelid, closely applied against the periphery of the cornea. The arcus is sometimes completed by the union of the superior and inferior semicircles. The resistance of the cornea in the aged becomes less through

the diminution of the current of the aqueous humour. The anterior chamber is in fact smaller, the iris having become slightly convex in front, while the cornea has lost somewhat of its convexity.

It has been said that the arcus senilis is a kind of atrophy of the cornea. This could only be brought about by a defect in its nutrition, in which case its opacity would commence in the centre rather than at the periphery, it being admitted by almost every one that the cornea derives its nutrition at the expense of the surrounding membranes.

*Gazette Méd.* 1857, No. 46.

## ON THE APPLICATION OF THE FORCEPS WITH ONE HAND.

By M. HATIN.

The author presented a memoir upon this subject to the Académie de Médecine in 1851, and in this second paper confirms by additional testimony the account he then gave of the advantages attendant upon this mode of applying the forceps, and replies to the objections which were made to his first paper.

His plan implies the introduction of the entire hand, when the object is to apply the forceps either at the superior aperture, or within the cavity of the pelvis; and this has been stigmatised as a both "useless and painful procedure." It however gives a facility and security during the application which is not to be attained by the ordinary procedure, in which the fingers scarcely reach the os uteri. There is then great danger of the blade guided by them slipping, and after it is fixed, when any obstacle presents itself to the delivery, all becomes doubt and hesitation in ascertaining the nature of the obstacle. When the entire hand is introduced the fingers are able to accurately fix or correct the position of the blade, and prevent the danger of an inefficient application leading to slipping and the perforation of the soft parts. The pain of the introduction of the entire hand is considerable, but it is only momentary, and the distension of the vulvar ring over is not reproduced during the various movements of the hand, which can be carried in all directions, without the employment of farther efforts to maintain its position. When the fingers only are introduced, the portion of the hand detained externally inflicts considerable contusion on the vulvar ring during the various efforts made to advance the fingers, or only to retain them *in situ*. The pain in the one case is momentary, but in the other may be extended over a very long period.

By the ordinary procedure, the left blade of the forceps is guided along the fingers of the right hand introduced into the vagina, while the right blade is guided by those of the left hand; so that after fixing one blade the fingers have to be withdrawn, and those of the other hand introduced. By M. Hatin's plan, after the fixing of one blade, guided by either hand, in place of withdrawing this hand it is carried round to the other side of the pelvis, and the other blade slid along it. The application can in this way be more certainly and more regularly made; and the second blade can be almost as easily fixed as the first. By the usual plan, after having fixed the first blade, and confided it to an assistant, the accoucheur, withdrawing his hand, possesses no means of controlling the relations of this blade with the head, nor of immediately re-establishing them when they become changed, either by the assistant or by some movement of the patient. The force he is obliged to use to pass the vulvar ring, already occupied by the first blade, while introducing the second, may readily lead to the displacement of the former, especially when conjoined with the movements of the patient, induced by the pain thus caused. The fixing the second blade is always difficult, and sometimes, when the head is at the upper orifice, may be impossible. In M. Hatin's procedure, the hand having fixed the first blade, does not abandon the head, but passes around it when free, or below it when fixed, and is enabled at once to ascertain and rectify any displacements that may occur, and is ready for the direction and application of the second blade. No agitation or movement of the patient need take place, as this is easily slipped in along the wrist and palmar surface. This is a much shorter process than when the hand is taken out and re-introduced. For the purpose of bringing the left hand, introduced in a state of semi-supination, from the right to the opposite side of the pelvis, it is only necessary to execute a simple movement of rotation, which causes it to pass into a state of almost complete supination. The movement is accompanied by no contortion of

the trunk or limbs; and at most an inclination of the hand towards the ulnar edge of the forearm would be required, if it were desired to carry it to the neighbouring cotyloidean region, which is rarely the case. The author's practice has been adopted by M. Chailly and other accoucheurs with success.—*Gazette Méd.* 1857, Nos. 48 and 51.

## EXCERPTA MINORA.

*Typhoid Fever in Algeria.*—M. Cordier states that in Algeria typhoid fever is never met with among the Arabs, nor among acclimatised Europeans, emigrants, indeed, only being liable to its attacks during the first year of their residence. According to M. Boudin's ideas this would be explained by the antagonism between typhoid fever and malarial diseases which are there prevalent. M. Cordier, however, believes that although some relation may exist between the two facts, no law on the subject can be laid down.—*Union Méd.* 1857, No. 105.

*Syphilitic Enteritis.*—M. Cullerier in 1854 called attention to this form of secondary syphilis, and recently one of his pupils, M. Pilon has published a thesis upon the subject. It manifests itself in the form of submucous gummy deposits, which do not go on to ulceration, but induce obstinate diarrhoea, and other symptoms of enteritis. It is by far most often observed in children, but it is also met with in the adult. It is a case that calls for delicate appreciation, as the mercurial treatment so far from being contraindicated constitutes the means of cure.—*Gaz. des Hôp.* 1857, No. 66.

*Laceration of the Lung without Injury to the Thorax.*—An example of this lesion, which has been well described by M. Gosselin at length in the *Mémoires de la Société de Chirurgie*, tome i. occurred recently to M. Dalmemesche, a provincial practitioner. A strong man, aged 24, was crushed between two railway waggons while in the act of coupling them, the compression taking place at the middle of the thorax. He died in a few hours, and at the autopsy considerable emphysema of the trunk and face was found, as well as a laceration of the middle lobe of the right lung, to the extent of about ten centimetres. There was no fracture whatever of the sternum, the ribs, or their cartilages; and the most minute examination failed to detect any laceration whatever in the pleura. No other organ was injured.—*Ibid.* No. 61.

*Diabetes in relation to Gangrene.*—As the conclusions of an interesting review of recent writings upon this subject, M. Fritz states:—1. That inflammatory and gangrenous affections of the skin and spontaneous gangrene are sometimes developed in persons who have suffered from diabetes for a greater or less time. An intimate relation exists between the two facts, but no theory at present satisfactorily explains such connexion. 2. By curing or palliating the diabetes, the cause of these affections, we may hope for the cure of the latter. 3. When these affections pursue their habitual course in non-diabetic subjects, they do not seem to be accompanied by sugar in the urine. 4. Nevertheless, in some rare cases diabetes seems sometimes to appear in the acute form, in persons to all appearance in previous good health, during the course of extensive anthracoid inflammations, having a rapid course, and accompanied by severe septic symptoms.—*Archives Gén.* Feb. p. 215.

*Facial Paralysis as a sign of Cerebral Hemorrhage.*—M. Trousseau observed that in facial paralysis properly so called, that in which the seventh pair is alone concerned, the loss of motor power is ordinarily complete and absolute, while when it depends upon cerebral hæmorrhage it is never complete. There may be some difficulty in the movements of the mouth, but nothing comparable to that seen in paralysis of the seventh pair; and we never find the paralysis of the orbicularis palpebrum carried to the same extent. The patient is always enabled to cover a portion of the eyeball, which is not the case in facial paralysis. M. Trousseau, in fact, has never once witnessed paralysis of the seventh pair which was not complete at least at its commencement, nor, on the other hand has he seen a single case of facial paralysis, dependent on cerebral lesion, and accompanied by general hemiplegia, in which the paralysis of the orbicularis was carried thus far. It is therefore a diagnostic sign of importance.—*Gaz. des Hôp.* 1857, No. 84.

*Treatment of Apoplexy.*—Regarding the cerebral hæmorrhage when once produced as a "fait accompli," M. Trousseau adopts no treatment, resolution of the effused blood taking place as well or better when nothing is done. In place

of bleeding such a patient, keeping him in bed and starving him, he makes him sit up, allows him to eat, and abstains from medication. Since he has adopted this plan of procedure he feels convinced that his patients have recovered better and more rapidly than when he was in the habit of keeping them in bed, and resorting to medicinal treatment.—*Ibid.*

## GENERAL CORRESPONDENCE.

### OPIMUM IN UTERINE HÆMORRHAGE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I quite coincide with the views expressed by Mr. Gabb in the *Medical Times* of February 13th, as to the value of opium in producing uterine contraction during labour in cases of deficient power from exhaustion or fatigue.

The stimulating effect of a moderate dose of this drug is well shown in a case which has recently occurred in my practice, and as one instance amongst others I relate it.

I was summoned, February 27th, at midnight to attend Mrs. P. I found that the liq. amnii had escaped without any pain, at 3 p.m., on the 25th; in about eight or ten hours she suffered considerably from spurious pain, which she recognised, and did not in consequence send for me. Owing to this pain she obtained very little sleep or rest from the time of the escape of the waters; and when I saw her she was much wearied from sleeplessness and fruitless pain. I found the os uteri dilated to the size of a five-shilling piece, and very dilatable, and the vagina in a favourable condition for a speedy termination of the labour. After waiting a time and finding the pains decrease in strength and frequency, I gave her a full dose of secale: the effect was *negative*. Another hour having elapsed, and the pains less satisfactory, I gave her twenty-five drops of laudanum in a little water. In ten minutes, a vigorous pain occurred; this was rapidly followed by three others, and the child was born. Another pain expelled the placenta, and the uterus contracted firmly. Mrs. P. has had no pain since; she is, in fact, quite well.

I am, &c.

R. F. SNARE.

Bolton-le-Moors, March 1st, 1888.

### TREATMENT OF BOILS AND CARBUNCLES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have lately, in common with every one else, had a great many cases of boils and carbuncles. I have tried almost all the ordinary methods of treatment, and find that if a carbuncle or boil be seen in its earliest stage, it may almost always be dispersed, or prevented from acquiring any great size. My plan is to order a thick solution of the aqueous extract of opium, of the consistence of treacle, to be painted on and around any suspicious spot that may arise. This soon dries, forming a coating, which requires renewing three or four times a day. Generally twenty-four hours' application is sufficient to arrest the further spread of the inflamed spot. I then order a plaster of equal parts of soap, mercury, and opium, spread on thick leather, to be placed on the spot. If there is a pustule, I evacuate it, and leave a small hole in the centre of the plaster to allow of the escape of any matter, or if painful, for the application of the opium and poultice. When it is desirable to poultice, I take care that the plaster is large enough to protect the surrounding skin, and I discontinue the poultice as early as possible. In this way, with early attention to small spots and a limited amount of poulticing, combined with ordinary care in diet, occasional aperients and tonics, of which last I prefer bark and nitric acid, I seldom find any difficulty in preventing the successive crops of boils now so common.

When called in at a later period, or if in spite of treatment a boil or carbuncle will have its course, I think strong nitric acid to be the best application, using it freely two or three times, removing the dead tough slough before each application, supporting the margins with the plaster, and poulticing freely. The beneficial action of the opium depends upon the local influence which it exerts upon the capillaries, small arteries and nerves, lessening pain, favouring exudation from the engorged vessels around the central spot, while nearer the

circumference it hinders the spread of the zone of active congestion, counteracting the stimulating effect of the inflamed spot upon the surrounding nerves and blood-vessels. This is shown by its lessening the throbbing, heat and redness, limiting it to the spot alone from which a small deep core has frequently to be removed, the surrounding parts soon recovering, if supported by the plaster.

The use of the plaster is obviously to give support to the inflamed vessels, and to protect the surface from the atmosphere, and is useful in all cases, and in all stages.

I am, &c.

BUXTON SHILLITON.

## REPORTS OF SOCIETIES.

### THE PATHOLOGICAL SOCIETY.

TUESDAY, MARCH 2.

Dr. WATSON, President, in the chair.

Dr. FULLER showed an

#### OVARIAN CYST OF UNUSUAL FORM.

The woman had been tapped four years before her death for ovarian dropsy, and the cyst had never afterwards refilled. She died of disease of the liver. At the autopsy a cyst of the left ovary was found, containing about a quart of fluid. The interest of the specimen consisted in its having a prolongation downwards, which passed upon the bladder and rectum. She had during life suffered much from irritation of those viscera. The ureters were much dilated, apparently from the pressure of the cyst upon them.

Dr. HARLEY next showed specimens of

#### DISEASED SUPRA-RENAL CAPSULES.

The subject of the case was a woman, aged 33, who had been treated by Dr. Sanderson for more than a year for dyspeptic symptoms, and anæmia. All treatment had been unavailing, and during the last six months a peculiar kind of "sallowiness" had been present and led to a diagnosis of supra-renal capsular disease. Both capsules were found disorganised. The bowels were matted together by adhesions. The liver was large and congested, and contained some miliary tubercles.

In answer to a question from the President as to the exact character of the change in colour of the skin, Dr. Harley stated he supposed it must have been more than mere sallowness to have led to a diagnosis of "bronzing." Dr. Mackenzie's notes, however, did not state more than that peculiar sallowness existed.

Dr. HARLEY next showed

#### DISEASED SUPRA-RENAL CAPSULES FROM A RAT.

The animal had seemed in good health when it was submitted to the operation of extirpation of the bodies in question. The capsule selected was found infiltrated with tubercle. The animal died two days after, and on examining afterwards the other capsule was also found diseased.

Mr. HENRY THOMPSON showed a

#### DISEASED SUPRA-RENAL CAPSULE, WITH BRONZED SKIN.

A woman, aged 81, had died of bronchitis in the Marylebone Infirmary, after having been an inmate of it for about a month. Her skin had been noticed to be remarkably bronzed during life, and she had stated that she had been getting darker for a year past. One supra-renal capsule was found disorganised, the other being healthy. The bronzing had been very marked in almost all parts of the body. The portion of skin shown to the Society was taken from beneath the axilla, and was a fair average specimen. It was very dark, and under the microscope showed a thick layer of pigment. Respecting the constitutional symptoms the history was imperfect.

Dr. HARLEY stated he did not feel certain on looking at the specimen that the destruction was so complete as Mr. Thompson thought. He had often seen the supra-renal bodies fatty and much changed in elderly people.

Mr. JOHNSON brought before the Society a specimen of  
**NECROSIS OF THE TIBIA IN AN INFANT.**

The infant was a twin. The other was born dead, and somewhat decomposed. The patient herself was a feeble, puny baby from the first. An abscess formed over one tibia at the age of three weeks and broke. Severe ulceration and stomatitis preceded death. Its father had had secondary syphilis before marriage. The mother was very delicate, but showed no specific symptoms. It was her first confinement. The specimen showed a loose portion of dead bone in the tibia.

Dr. LEARED showed

**THE HEART FROM A CASE OF DEATH FROM ANÆMIA.**

A girl, aged 11, had died in the "Great Northern" Hospital after a six months' illness. Her family all appeared healthy, and she had been well fed. She was emaciated, and very pale. The stomach was irritable, and frequent vomiting occurred. She sank the day after admission into the Hospital. At the autopsy all the organs were found bloodless, but no structural disease was discoverable on the most careful examination. Large fibrinous coagula were found in the heart and large vessels, but the blood, which was exceedingly poor, did not coagulate. Dr. Leared had visited the house in which the girl had lived, and had been unable to detect any unhealthy conditions. He was inclined to refer the fatal event to the coagula in the heart.

Dr. BRISTOWE could not but differ from Dr. Leared as to the connexion of the coagula with death. He thought it had been generally acknowledged that these coagula formed during the act of dying. They were very common indeed.

Mr. HOLMES showed a

**SOFT POLYPUS FROM THE RECTUM OF A CHILD.**

The patient was a little boy, the son of a surgeon. He had passed blood by the rectum, the cause of which for some time could not be explained. At length the polypus was detected extruded, but it passed out of sight again before it could be secured. At a subsequent time, however, it was ligatured, but broke down during the operation, and came away. All symptoms had since disappeared. Mr. Holmes remarked upon the rarity of this form of polypus, and stated that authorities differed as to whether it was more frequent in children or in adults.

Mr. CURLING thought they were not so rare as Mr. Holmes supposed. He had seen several, and removed one only three weeks ago. He thought there could be no doubt that they were more common in children than in grown-up persons.

Mr. CHALK next brought before the Society a specimen of  
**DISEASED HIP-JOINT FROM AN INFANT.**

There was an abscess at the upper and outer aspect of the thigh, communicating with the cavity of the joint through a small aperture in the capsular ligament. Caries of the head and neck of the femur existed, with total destruction of the ligamentum teres, and synovial appendages; incipient caries of the cotyloid cavity. The cerebral symptoms, which were occasioned by a slight contusion from a fall, and the infliction of a small wound on the side of the head by means of a steel fork which the child held in her hand at the time of the accident, terminated fatally in nine weeks, previous to which the hip disease had progressed favourably.

The case derived its interest principally from the comparatively rare occurrence of hip disease at such an early period of life, (as shown by the tabular results of 129 cases among females distributed over quinquennial periods, up to the age of 55, of which there were three cases only prior to the fifth year), and from the slight local injury by which the cerebral disorder was excited, a result, however, by no means uncommon among the scrofulous where, as in this instance, a pre-disposition to the disease had existed. The child was only three years old at the date of death, and the disease of the hip had then existed seventeen months.

Dr. OGLE showed a specimen of

**MELANOTIC CARCINOMA OF THE BRAIN.**

Preparation showed two large masses of reddish-brown solid material, occupying the superficial part of the cerebral hemisphere. These had much the appearance of masses of extravasated blood, except that in one place a small part of the growth was of a light colour, much like the appearance of

ordinary encephaloid growth. Examined microscopically, the mass showed multitudes of large nucleated cells, many of them containing pigment, mixed with much of the remains of extravasated blood. The preparation was removed from a man affected by hemiplegia, and from whom during life enlarged carcinomatous glands in the groin had been removed by Mr. P. Hewett and Mr. Lawrence. The chain of symptoms calling for special attention were during life as follows:—Loss of power and sensibility down the side of the body opposite to that in which the deposit in the brain existed; partial facial paralysis; vomiting; intense pain in the head, at times accompanied by double vision; peculiar grasping and clenching of the paralysed fingers on yawning, and a peculiar agitation of the affected limbs when the patient's mind was affected by emotion. There had been "no fit" and "no loss of consciousness." The patient died from sudden apnoea, apparently from affection of the pneumo-gastric nerves. Melanotic deposit also existed in several of the abdominal viscera.

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY.**

THE Annual Meeting was held at the rooms of the Society, Berners-street, on Monday evening, the 1st inst. Sir James Locock, President, in the chair.

The abstract of receipts and payments showed a balance of £93 15s. in the hands of the Society.

The report stated that during the past year, the admissions have been more numerous than in the preceding one, seventeen resident and four non-resident fellows having been elected. During the same period, one foreign honorary fellow, five resident, and nine non-resident fellows have been removed by death. The President and Council congratulated the Society upon having established their claim to the non-payment of parochial rates upon the premises. The sum of £73 had been incurred in prosecuting an appeal to the Court of Queen's Bench. The Librarians reported that 321 new works, exclusive of journals, had been added to the Library, of which 114 were donations, and 207 were purchased. They also reported the completion of the various alterations and improvements in the catalogue, which have been in progress during the last three years.

Dr. TODD moved that the report be adopted, and circulated among the fellows. The report, he need scarcely remark, showed that the Society was in a highly prosperous condition, perhaps the most prosperous condition it had ever been in. He was sure all would gladly join in wishing that the Society would continue for many years to flourish, and to be a sort of centre for the union of all branches of the Profession.

Mr. PAGE seconded the adoption of the report.

The motion was carried unanimously.

The PRESIDENT then delivered the annual address, in which he gave the customary biographical sketch of those Fellows who had been removed by death since the last annual meeting. During the thirty-five years, he said, that he had had the honour and the advantage of belonging to this Society, he had seen many a stronger and more likely man carried off before him; and year after year the circle of his professional brethren, amongst whom he formed his earliest friendships, had become narrower and narrower. The last year had witnessed the removal of many of them. Many of them were well known as fellows of this Society; but many of them were out of its pale, or it would have been grateful to his feelings to have borne his humble testimony to their merits and character. The list of deceased resident and non-resident fellows, whose careers were then sketched, comprised Dr. Robert Hume; Dr. Joseph Ager; Mr. Lonsdale; Mr. Keate; Mr. Taunton; Sir Robert Carswell; Dr. John Howe, of Edinburgh; Mr. Joseph Wickenden, of Birmingham; Dr. James Ogle, of Oxford; Dr. George Frederick Mühry, of Hanover; Dr. John Johnstone, formerly of Old Burlington-street, who died at Paraguay; Dr. Peter F. Luard, of Warwick, late of Florence; Mr. Robert Brown, of Preston; Dr. Hugh Bohn, Inspector of Army Hospitals, who died at the age of 81, on the 13th of February; and Dr. Conrad Jacob Temminck, of Leyden. The President concluded his address in these terms:—"Gentlemen, this portion of my task is done. But no

having been willing to interrupt our ordinary meetings with any intrusion of my personal feelings, this is literally the first public opportunity I have had of thanking you for the high honour you have conferred upon me, by placing me in this chair. No one is more ready to acknowledge that I owe this to the accident of my becoming one of the seniors, and amongst the oldest in standing of those who have not already attained this distinction. For many years I have been too much engrossed with the more active pursuits of my profession, to be able to devote myself to those labours which might have increased, if not enriched, our medical literature; and I felt I had neither health nor strength enough to have attempted both of these departments. Many a man of much higher talents, more deep research, more extensive acquirements, may be found amongst our members, who have not been so fortunate in life as I have been; but their names will live, and their works will be quoted, when my more ephemeral career has been long forgotten. But I trust, when a future President gives you a little sketch of my biography, amongst the list of those fellows who have died during his year of office, that he will not at least be able to say, that I have done anything to forfeit your good opinion, that I have not honoured and loved my Profession, or that I have not been grateful to the Almighty for the many undeserved blessings I have obtained."

Dr. WEBSTER proposed a vote of thanks to the President for his address, and requested that he would consent to its publication in the Proceedings of the Society.

Mr. ARNOTT seconded the motion.

The President, in returning thanks for the honour done him, said he must leave it in the hands of the Council to decide as to what should be done with the address.

As it now wanted a few minutes to the time for closing the ballot, a pause ensued, of which the President took advantage to call attention to the large number of new names proposed to be put upon the Council. It was true some of the former members, he said, did not wish to serve again; but the reason why others had been omitted was because they had been remiss in their attendance. He would remind gentlemen who might be elected, that it was a very important part of their duty to attend, because, by the rules of the Society, unless members of the Council attended a certain number of times in the course of the session, they could not be eligible for reelection.

The ballot closed at the expiration of an hour, and the Secretaries, Mr. Robert Taylor and Mr. Spencer Wells, reported that the gentlemen whose names appeared upon the printed list (given in our columns last week) had been unanimously elected to fill the various offices for the ensuing year.

The meeting then closed.

TUESDAY, Feb. 23, 1858.

Sir C. Locock, Bart., President, in the chair.

A paper, by Dr. F. W. MACKENZIE, was then read,  
ON THE ACTION OF GALVANISM UPON THE  
CONTRACTILE STRUCTURE OF THE GRAVID  
UTERUS,

AND ITS REMEDIAL POWERS IN OBSTETRIC PRACTICE.

The author in the introductory remarks drew the attention of the Society to the present state of professional opinion respecting the effective and remedial powers of galvanism upon the gravid uterus, and he pointed out the very different conclusions which different observers had arrived at. In this divided state of opinion, it had appeared to him that some further investigations might be usefully undertaken, and he submitted that two questions of a preliminary nature require to be decided before the agent could be satisfactorily employed in midwifery—1st, the nature of the influence exercised by it upon the contractile structure of the gravid uterus; and 2ndly, the best mode of applying it so as to obtain the full benefit of such influence. Believing that these questions could not be satisfactorily solved by observations made exclusively upon the human female, the author had planned and instituted some experiments upon the gravid uterus of the lower animals, in which the organ was exposed, and the exact influence exercised by it was observed. From these experiments it was shown that galvanism exercises a remark-

able and peculiar influence upon the uterine fibre, and it further appeared after many observations that this was most powerfully exercised when the galvanic current was directed longitudinally through the uterus from the upper portion of the spinal cord in a sustained and continuous manner. The local application of galvanism to the uterus was less effective; individual shocks produced no appreciable effect upon it, and a current directed transversely through the organ produced only a partial contraction of it in the direction of the current. Guided by the information thus obtained, the author had employed galvanism in the manner suggested by these inquiries in several very critical cases with remarkable success. The first referred to was that of a lady who had had repeated floodings in connexion with an early abortion, owing to an imperfect separation and expulsion of the ovum. In this every available means had been tried to stimulate the uterus and control hæmorrhage without success, and the patient's condition had at length become highly critical. In this emergency a sustained current of electricity was directed longitudinally through the uterus from the upper portion of the spinal cord, and under its influence the cervix uteri became relaxed, and expanded after the first application, and uterine action set in after the second, which was followed by the expulsion of an organised membrane, upon which the hæmorrhage ceased, and the patient rapidly recovered. The second was a case of placenta prævia, in which several alarming hæmorrhages had occurred before labour had commenced. In this a sustained current, applied in the manner stated for six hours, not only prevented any further hæmorrhage, but so accelerated the dilatation of the os uteri, that the hand was readily introduced, and delivery completed with safety to the patient, although the child, from the extensive separation of the placenta, was still-born. In a third, excessive hæmorrhage had occurred in a primipara in the last month of pregnancy, and, as the placenta was felt to be attached to the cervix uteri, it was thought desirable to bring on delivery. With this view a sustained current was applied for three hours; the hæmorrhage was almost immediately arrested, and the labour had advanced so rapidly, that in a few hours afterwards it was completed by the birth of a living child. The author referred to other cases, in which he had successfully employed galvanism in obstetric practice, and, with reference to those related, submitted that they appeared to him to warrant the three following conclusions—

1. That a sustained current of electricity of moderate intensity, passed through the gravid uterus in the manner described, exercises a remarkable influence in increasing the tonicity and contractility of the uterine fibre.

2. That in such increased tonicity or contractility of the uterine fibre, so excited and sustained, we have a powerful and reliable means of moderating and controlling uterine hæmorrhage, whether of the accidental or unavoidable variety, and of simultaneously accelerating the dilatation of the os uteri and the general progress of the labour.

3. That such sustained current of electricity may be continued for a lengthened period, when the object to be attained requires it, without any appreciable pain or inconvenience to the mother or danger to the child.

In conclusion, the author briefly considered the objections which had been raised to the employment of galvanism in obstetric practice, and pointed out some fallacies, as he believed, in the conclusions which had been arrived at by Dr. Simpson.

The President asked if Dr. Mackenzie had had the opportunity of trying, as a galvanic apparatus, the chains of Pulvermacher, because if they were found to produce sufficient effect, they would be very advantageous from their portability. That they were powerful re-agents he had not the slightest doubt, for within a few days he had seen a link of twenty-four chains decompose water as readily as a common galvanic apparatus would do it.

Dr. MACKENZIE said he had no experience of the chains mentioned by the President. They had, however, been recommended to him, and the hint thrown out by the chairman might, no doubt, be beneficially acted upon.

Mr. FOSTER said he was present at one of the cases referred to by the author, and went to it with a prejudice against the use of galvanism in the manner described, believing that it could have no effect over the contraction of the uterus, and in preventing hæmorrhage in placenta prævia. The result, however, satisfied him that Dr. Mackenzie's experiments de-

served the careful attention of all who followed obstetric practice. He had never seen anything that controlled the hæmorrhage of placenta prævia so perfectly.

Dr. GRAILEY HEWITT said that in cases of placenta prævia, the life of the child, as well as the life of the mother, should be considered, and it was well known that any circumstances which produced a strong, powerful, and continued contraction of the uterus, were injurious to the well-being of the child; this, in fact, was one of the chief objections to the use of the ergot. He wished to ask Dr. Mackenzie, if the child in the first case was born alive.

Dr. MACKENZIE said that in the first case, the placenta was so centrally attached that it was impossible the child could have lived. In the second case, the child was born alive, but died about three days afterwards, of disease of a natural character, there being no evidence of its having sustained any injury from the galvanism.

The PRESIDENT said the Society must feel deeply obliged for the interesting paper of Dr. Mackenzie, and he hoped that further experience in the matter would throw additional light on the subject. At present it was, perhaps, hardly fair to estimate it, on account of the many changes in the condition of the uterus, which were accidentally produced, and occurring without any explicable cause.

Dr. TYLER SMITH thought that Dr. Mackenzie had hit upon the right class of cases for the use of galvanism, namely, cases where the os uteri was not dilated, and where it was required to contract the uterus. Cases had occurred, however, in which similar changes to those described by Dr. Mackenzie had been produced, when galvanism had not been used; but he had had opportunities of using galvanism in cases of closed uterus containing a large polypus, where the uterus would remain quiet for days except when the galvanism was employed. He believed he had been able to remove polypi from the uterus by means of galvanism, when they could not be got out by other means. In the lower animals he had been able to induce labour entirely by the action of galvanism, and he remembered a case in which a patient was relieved from imminent danger by the use of galvanism in promoting the peristaltic action of the intestines.

Dr. MACKENZIE remarked that his practice was the result of induction, and not of casual observation. He had performed experiments upon the lower animals, and had arrived at precisely the conclusions which were subsequently established in his practice at the bedside, the results having precisely corresponded to what he had anticipated.

A paper, by Mr. COOPER FORSTER, was then read,

#### ON THE DIRECTION OF THE NUTRITIOUS FORAMINA OF THE LONG BONES.

In this brief communication, the author, after describing the sources of blood supply to the long bones, called attention to the following facts:—That the epiphyses of the various bones invariably join their respective shafts earliest at that extremity towards which the nutritious foramen is directed; that where there is only epiphysis, the nutritious artery always takes a course from that part; consequently that in early life the best nourished and most vascular end of any one of the long bones, and, therefore, that end at which union of the epiphysis with the shaft will first take place may be predicated from the direction of the various foramina; and the author concluded by remarking, that the direction of the nutritious foramina being in early life invariably towards certain joints, these are at that time most frequently the seat of disease, and that at adult age, as the epiphyses become united to the shaft of the bone, the joints away from the nutritious foramina are those most commonly affected.

The Society then adjourned.

### MEDICAL NEWS.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on February 25, 1858:—

ELLIS, HENRY, Bangor.

GREEN, CHRISTOPHER, Brixham, Devon.

HODGES, WILLIAM, Brecon, South Wales.

POULSEN, FREDERICK GEORGE, Bristol.

THOMAS, RICHARD, West Indies.

—As an Assistant, PHILIP COWEN, Harleyford-place, Kennington.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 19th inst.:—

BLACK, ALEXANDER OSMOND, Regent-square.

COOK, EDWARD, Hay, Breconshire.

CORBET, DAVID, Orsett, Essex.

DWYER, JAMES, Tuam, County of Galway.

HOOVER, JOHN HENRY, West-square, Southwark.

JACKSON, THOMAS, Penrith, Cumberland.

JOHNSON, BURDETT, Somersham, Hunts.

MERCER, ARTHUR WYATT, West Drayton, Middlesex.

MOORE, JAMES EMPY, Barbadoes, West Indies.

PEARSE, ROBERT EDMUND, Edmonton.

SHUTTLEWORTH, ROBERT, Army.

SKINNER, HORATIO GEO., Great Grimby, Lincolnshire.

SPRING, JOHN, Boston, United States.

#### DEATHS.

BLAKE.—On the 28th ult., at the Grove, Camberwell, B. Blake, M.D., R.N., aged 76.

ELLERY.—The *Ceylon Mail* says:—"We are sorry to have to announce the death of Dr. Ellery at the Mahatenne Estate on the 22nd inst. Dr. Ellery has been for several years established in Ceylon in the Medical Profession. He made many friends, who will deeply regret hearing of his death."

ROULSTON.—On the 22nd ult., at Albion House, Low Harrogate, John Roulston, M.D., late House Surgeon to the Leeds General Infirmary.

#### APPOINTMENTS.

LIVERPOOL ROYAL INFIRMARY SCHOOL OF MEDICINE, Chair of Botany.—Dr. Cuthbert Collingwood has been elected to this Chair, vacant by the resignation of Mr. Archer.

LIVERPOOL EYE AND EAR INFIRMARY.—Dr. Nevins has been elected to the office of Honorary Surgeon to this Infirmary, vacant by the resignation of Mr. Neill.

OVERCROWDED STATE OF HOLBORN-BUILDINGS.—The following are extracts from the weekly report of Dr. Letheby, the Medical Officer of Health:—"In eight of the houses there are 63 men, 90 women, and 89 children, in all 242 persons: and, in many cases, the overcrowding is not merely unwholesome and dangerous to public health, but it is also highly indecent. One room lodged three men and one woman, another three men and two women, another two men and three women, another one man and four women, and there are several instances where there are two men and two women, or one man and two women, besides a troop of children. All the rooms are small, their cubic space being from about 800 to 1,600 cubic feet, and in some of the smallest of the rooms there are from five to seven persons, giving an area of less than 160 cubic feet per head, a space that is barely sufficient to supply the requirements of respiration. The poverty of the inmates is extreme. They have little or no furniture. A heap of rags in most cases is all that they have to lie upon, and in their endeavours to maintain the warmth of the rooms they carefully shut out the external atmosphere by stopping every aperture that can give access to the cold and fresh air. Ventilation is in this way almost entirely checked, and the factor of the rooms is abominable." And this is the richest city in the world, where model lodging-houses pay a good dividend, to say nothing of higher motives!

KING'S COLLEGE HOSPITAL.—The Committee's 19th annual report states the number of in-patients for the past year at 1,461, and the out-patients at 26,156—total, 27,617. The average length of residence of the patients in the house, was 27 days, and the average cost of each patient £4 5s. The current income of the year 1857 was £5,577 4s. 6d., and the expenditure £6,851 16s. 2d.

A DEPUTATION from the Epidemiological Society had an interview with The Hon. W. Cowper, M.P., at the office of The General Board of Health, Whitehall, on Thursday, the 25th ultimo. The deputation consisted of Dr. Babington, F.R.S. (President); Dr. McWilliam, F.R.S.; Dr. Waller Lewis, F.G.S.; Dr. Camps; Mr. Morson; and Dr. Seaton. The object of the deputation was to draw the attention of the Public Health authorities to the importance of legislation in regard to vaccination and the prevention of small pox.

## TO CORRESPONDENTS.

## THE SALE OF MEDICINES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As the Medical Reform Bill is to be brought forward this session, and in all probability will become law, I would wish to suggest one clause that I think is imperative in raising the Profession to its proper status, which is, that Pharmacy should not be practised by Medical Practitioners, but that they should write prescriptions, charging a fair sum for visits, and that Druggists should compound the medicines, but that if they at any time attempted to prescribe, they should be punished by fine. Some may think that this would not work well in rural districts, but I am quite certain that any place that will support a Surgeon will support a Druggist also.

If we continue to combine trade with our Profession we must expect to rank lower than the other liberal Professions, and be behind the Continental nations, and even our own colonies. I am, &c.

MEDICUS.

DR. PEARSE OF NEWCASTLE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—After quoting an advertisement headed "Physician's Advice within reach of all," you inquire in the *Medical Times* of the 13th inst.: "Can this be the Dr. Pearse described in the Medical Directory, *inter alia*, as Lect. on Med. Jurisp. Newcastle Coll. of Med., etc. etc.?"

I send you in reply the following extract from a letter I have just received from Newcastle:—

"Dr. Pearse is no longer connected with this College. When the announcement first appeared in the *Express*, and was placarded on the walls of the town, the Students signed a protest against it, which was sent to Dr. Embleton for presentation to the Council: shortly after this Dr. Pearse resigned his lectureship." I am, &c. OBSERVER.

*Errata.*—In Mr. Jones's letter in our last number, in the fourth line of the third paragraph, for "ablation" read "whatever."—In Dr. Leared's paper in our last number, p. 213, second column, line 18 from the bottom has been transposed. It should have been placed immediately before the third line from the bottom.

Mr. Wilkinson.—No such recommendation can be found in our pages.

Mr. Paget's paper, "On some Affections of the Voluntary Muscles," will appear next week.

E.S.—There is no good comprehensive British work on Hygiene.

Mr. Hulke's paper on the "Surgical Treatment of Glaucoma," shall appear on the 27th inst.

Dr. Renton's letter arrived too late for insertion this week.

Dr. Robinson's case of "Fibrinous Impaction of the Pulmonary Artery" shall appear next week if possible.

*Aspirant.*—Mr. Gamgee and Mr. West are both Surgeons to the Queen's Hospital at Birmingham, but the controversy as to their seniority is still carried on.

*Chorley.*—No Physician, Surgeon, or Apothecary, actually practising, is liable to serve on a jury.

*A Student.*—The Apothecaries' Company do not recognise an apprenticeship to a Pharmaceutical Chemist.

*Critic.*—It is quite unnecessary to expose such obvious blunders. The writers, as Faraday says, are "ignorant of their own ignorance;" but readers are better informed.

Dr. Medlock's letter on Chlorodyne arrived too late for insertion this week.

Mr. Hiliard's wood-cut had not arrived in time for this week's impression.

Papers are in type by Mr. Muskett, Dr. Priestley, and Mr. Paget.

COMMUNICATIONS have been received from—

MR. PAGET; DR. CONOLLY; DR. SYMONDS, Clifton; DR. SIEVEKING; DR. BRYSON; MR. PRESOTT HEWITT; DR. M'WILLIAM; DR. MARCET; DR. GIBSON; DR. LEARED; DR. BIRKBECK NEVINE, Liverpool; DR. CAMPS; ROBERTSON-GENERAL, Edinburgh; DR. WILKS; DR. HASLEWOOD; SECRETARY, GENERAL BOARD OF HEALTH; DR. BAINES; MR. BARLOW; DR. TRASK and DR. WOOSTER, San Francisco; MR. SYMES; MR. KINGLAKE; MR. RIVERS; MR. M'DERMOTT; MR. JONES, Leamington; MR. DOUGLAS, New York; ROBERTSON-GENERAL; MR. PARNELL; MR. SNAPE; MR. HUGHES; MR. EVANS; DR. DEVENISH; MR. SANSON; MR. WALTERS; MR. ROULSTON; DR. RENTON, Edinburgh; DR. ROBINSON, Newcastle; DR. GEE; MR. FLETCHER; MR. JOHNSTONE; MR. DALRYMPLE; MR. BROWNE; MR. S. SMYTHE; MR. NICHOLL.

## APPOINTMENTS FOR THE WEEK.

March 6, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Bloxam, "On the Chemistry of the Elements which circulate in Nature."

MEDICAL SOCIETY, 7 p.m.: General Meeting. Mr. J. L. Milton, "On the Pathology and Treatment of Syphilis."

GUY'S PHYSICAL SOCIETY, 7 p.m.: Mr. Moxon, "On Injuries to the Head."

## 8. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopedic Hospital, 3 p.m.

MEDICAL SOCIETY OF LONDON, 8 p.m.: Anniversary; Oration.

NORTH LONDON MEDICAL SOCIETY, 8 p.m.

## 9. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Biology."

ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.: Mr. G. M. Humphrey, "On Excision of the Knee-joint;" and, if time, Dr. Tyler Smith's case of "Inversion of the Uterus."

ZOOLOGICAL SOCIETY, 9 p.m.

## 10. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Orthopedic Hospital, 3 p.m.

ROYAL COLLEGE OF PHYSICIANS, 4 p.m.: Croonian Lectures—Dr. Sutherland: "The Pathology, the Morbid Anatomy, and the Treatment of Insanity."

GEOLOGICAL SOCIETY, 8 p.m.

HUNTERIAN SOCIETY, 8 p.m.: Dr. Gull, "On some Cases of Apoplexy from Aneurism of the Cerebral Arteries."

## 11. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 12½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.

ROYAL SOCIETY, 8½ p.m.

ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."

MEDICAL SOCIETY OF KING'S COLLEGE: Mr. George Lawson, F.R.C.S. "On Gunshot Wounds of the Thorax; observed during the late Russian war."

## 12. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.

ROYAL INSTITUTION, 8½ p.m.: Dr. B. W. Carpenter, "On the lowest (Kleopod) Type of Animal Life, considered in its Relations to Physiology, Zoology, and Geology."

ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Lumsden Lectures—Dr. Tweedie, "On Fevers."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations are expected at this Hospital to-day (Saturday) at 2 o'clock:—Amputation of Foot (Perigoff); Trephining Tibia; Removal of Bursa Patella; by Mr. Fergusson.

## ORIGINAL LECTURES.

## A COURSE OF CLINICAL LECTURES

ON

## DISEASES OF THE KIDNEY.

By GEORGE JOHNSON, M.D. F.R.C.P.

Physician to King's College Hospital.

## LECTURE VI.

THE subject of my last lecture was a case of fatty degeneration of the kidney—a form of chronic Bright's disease in which the kidneys are usually found to be large, pale, soft, œdematous, and having throughout their cortical substance numerous small yellow fat-granulations. To-day I beg your attention to a form of disease which is characterised by a contracted, and a more or less hardened condition of the kidney. I shall show you that in several important particulars this disease differs from the other; differs from it not only in the morbid anatomy of the kidney, but in the physical and chemical characters of the urine secreted, and in the entire clinical history of the disease. The cases which you have lately seen in the wards will serve to illustrate the most important features of this form of chronic Bright's disease.

I will take as my first illustration the case of George N., aged 60, who was admitted into No. 4 Ward on the 1st December. I shall abridge Mr. Tonge's report of the case. The patient, who is a trunk-maker, has worked hard, lived well, and drunk pretty freely both beer and spirits, but he does not consider that he has been a hard drinker. He had scarlatina when a child; more than thirty years ago he had erysipelas of the head, and he has suffered from occasional attacks of what he calls rheumatic gout, affecting chiefly the small joints, since he was thirteen years old; he has also been ruptured since childhood; with these exceptions he has generally enjoyed good health until the commencement of his present illness, which occurred, as he believes, thirteen weeks ago. At that time he went from London to Brighton in an open third-class carriage; soon after this journey he was seized with shivering, and this was quickly followed by dropsical swelling of the legs. He returned from Brighton in about a week, and the dropsy continuing to increase he soon took to his bed, where he remained until his admission here on the 1st December.

The report of his condition then was as follows:—There is œdema of the feet and legs, the complexion is somewhat sallow, his mental faculties are dull and confused, the memory being impaired. He has a slight cough, but the pulmonary and cardiac sounds are normal. He complains of no pain, but there is some tenderness on pressure in the lumbar and in the right hypochondriac region. Percussion indicates that the liver extends some distance below the margin of the ribs on the right side. He has a good appetite, and sleeps well; the tongue is partially blackened by a steel mixture which he has been taking. The urine is passed in about the natural quantity; its colour is pale, its sp. gr. 1013; it is highly albuminous, the coagulated albumen occupying nearly one half the bulk of the liquid. On microscopical examination it was found to contain numerous small and large waxy-casts, and some granular casts, (see fig 7.) These granular casts are for the most part, composed of broken down and disintegrated gland-cells from the tubes of the kidney, and they usually indicate a chronic wasting form of renal disease.

Looking then to the history of this patient's illness, to his present symptoms, and to the appearances in the urine, we had no difficulty in arriving at the opinion that the chief disease was in the kidney, which was affected with that form of chronic Bright's disease which is characterised by atrophy and contraction of the kidney—a disease which we are in the habit of calling *chronic desquamative disease* of the kidney, because its most remarkable and characteristic feature is the crumbling down of the renal gland-cells which appear in the urine, partly in the form of scattered amorphous material, and partly in the form of those granular casts to which I have before alluded, (fig. 7, a. a.)

VOL. XXXVII. No. 963. NEW SERIES, No. 402.

Then, with respect to the question of prognosis, our opinion from the first was not only that the disease was incurable, but that it would very soon be fatal. It appeared highly probable that the renal disease had existed long before the first appearance of dropsy; the state of the patient's mental faculties showed that the brain was already suffering from urinæmia consequent on the failing function of the kidneys, and lastly, the copious sediment in the urine, composed, as I have before said, of granular and waxy casts, of various sizes, indicated that the disease was making rapid progress. You will find, as a rule, that in this form of renal disease the amount of sediment affords a pretty accurate measure of the rate at which the degeneration of the kidney is proceeding. The granular casts show disintegration and destruction of the renal gland-cells, and the large waxy casts, having the full diameter of the tubes of the kidney, indicate that the tubes in which they have been moulded have lost their epithelial lining, and are being filled with unorganised fibrin. The chief object of treatment was to ward off the apparent tendency to death by coma, and we considered that this might be most effectually done by moderate doses of purgative medicine, with counter-irritation over the kidneys, at the same time that the patient's strength was sustained by nourishing food. Accordingly, we gave him ten grains of the compound colocynth pill every night, and, with a view to counteract the anæmia, we prescribed the muriated tincture of iron, in doses of 15 drops with water three times a day.

FIG. 7.

a. a. Granular casts. b. Small waxy cast. c. Large waxy cast.

Many of you will remember to have seen that the drowsiness gradually increased until it passed into complete coma, the tongue became brown and dry, and he died, without the occurrence of convulsions or other important new symptoms, on the 13th December, that is, twelve days after his admission into the hospital.

On post-mortem examination we found, as we had anticipated, that the kidneys were in an advanced stage of atrophic Bright's disease, the left weighed three ounces and six drachms, the right, five ounces and two drachms. The greater weight of the right kidney was due to its containing three serous cysts, the larger of which was about the size of a small orange, and contained at least an ounce of liquid. The secreting structure of the two kidneys was equally wasted, each being reduced to about two-thirds of its natural size; the cortical portion was very thin, and the surface rough and granular.

The liver was large and congested, its weight being three and a half pounds, and its upper surface was connected with the diaphragm by old adhesions. You will remember that it had been noted that the liver extended some distance below the margin of the ribs at the time of the patient's admission.

In the chest we found the heart enlarged, its weight being seventeen and a half ounces. The left ventricle was much thickened. There was a slight ossific deposit at the base of two of the aortic valves, but not sufficient to interfere with their function, or to impede, in any appreciable degree, the

onward movement of the blood. The lining membrane of the aorta contained some atheromatous deposits.

The brain had an anæmic appearance, but in other respects seemed quite healthy.

We examined the kidney with the microscope, but of the result of that examination I will speak to you hereafter. I beg your attention now to one or two points in the pathology of this case. And first as to the cause of the drowsiness passing into coma. You saw that there was no appreciable structural change in the brain, and it can scarcely be doubted that the coma resulted from an accumulation of one or more of the constituents of urine in the blood consequent on degeneration of the kidney. The drowsiness was probably the result of a toxic influence of contaminated blood upon the brain, as much so as in the case of poisoning by opium. As to the precise nature of the toxic agent in cases of uræmic poisoning we are still in doubt. It has very generally been supposed that the symptoms in question are due to an accumulation of urea in the blood, but Frerichs has originated a theory that, not urea, but carbonate of ammonia which results from the decomposition of urea, is the immediate cause of the phenomena. (a) In support of this hypothesis Frerichs states that a large quantity of ammonia is exhaled from the lungs of patients who exhibit symptoms of uræmic poisoning, and he asserts that if such a patient be made to breathe upon a glass rod which has been dipped in hydrochloric acid, the presence of an abundance of ammonia is shown by the dense fumes which are thereby produced. Now we applied this test while our patient was in a state of half-consciousness, and we found that the fumes about the glass-rod were much less dense and copious than when the rod was breathed upon by one of ourselves. The explanation which suggests itself is, that the fumes are chiefly produced by the moisture of the aqueous vapour in the breath with the vapour of the acid, and the patient, with his brown dry tongue and lips, was evidently exhaling less moisture from the lungs than was contained in the breath of a healthy man. A short time since we tried the experiment upon another patient with precisely the same result. It is evident, therefore, that this test is quite insufficient for the purpose, and that it lends no support to the hypothesis of Frerichs.

One circumstance in this case to which I beg to direct your particular attention is the hypertrophy of the heart, and especially of the left ventricle, without the co-existence of any disease of the valves or of the large arteries, such as would impede the flow of blood, and so explain the increased bulk and strength of the muscular walls of the heart. In a very large proportion of cases of chronic Bright's disease, you will find this hypertrophy of the heart; sometimes associated with such disease of the valves or of the larger arteries as may be considered sufficient to explain the phenomenon; but not unfrequently, as was long since pointed out by Dr. Bright himself, there is no apparent organic cause for the marked hypertrophy generally affecting the left ventricle. The most probable explanation of this remarkable fact is that the blood, being contaminated by excrementitious materials in consequence of degeneration of the kidney, is impeded in its passage through the minute systemic vessels; the left ventricle, therefore, has to make unusual efforts to propel the blood, and in so doing it acquires an increase of bulk and strength.

That blood which has its qualities altered by an accumulation of excrementitious products, or by the introduction of foreign matters, is impeded in its passage through the minute subdivisions of the vascular system, has been proved by very numerous experiments and observations. I will not occupy your time by an account of these experiments, which you will find described in most works on physiology, but I wish now to remind you of one fact in the minute anatomy of Bright's kidney, which has a close relation to this subject. Some years since I first observed and described in the *Medico-Chirurgical Transactions* (vol. xxxiii.), a very remarkable thickening of the small renal arteries, and of the Malpighian capillaries, as occurring in all cases and in all forms of chronic Bright's disease. The thickening of the arterial coats is an instance of true hypertrophy of muscular tissue. It is often associated with a

dilated and tortuous condition of the vessels, particularly of the afferent arteries, (see ante, fig. 1, p. 1.) and the phenomena can be explained only by assuming that the blood is impeded in its passage through that portion of the vascular system of the kidney, which in the course of the circulation lies in front of the Malpighian vessels. This impediment to the flow of blood through the kidney, connected as it is with degeneration of the secreting tissue, and consequent imperfect excretion of urine is analogous to the obstruction of the pulmonary circulation which always occurs when, from any cause, the blood is insufficiently aerated. For instance, in cases of emphysema with chronic bronchitis, we have evidence of long continued obstruction to the flow of blood through the lungs in the dilated and hypertrophied condition of the right side of the heart.

Now one practical observation in connection with thickening of the renal blood-vessels in chronic Bright's disease. In cases of *acute* disease the urine often contains blood in variable quantity, while in *chronic* Bright's disease hæmaturia is of rare occurrence. The explanation of this fact is to be found in that thickened condition of the Malpighian capillaries, which I have described as occurring in all forms of chronic Bright's disease.

No rule of this kind is without exceptions, but dark-coloured, smoky, or decidedly blood-tinted urine, affords strong presumptive evidence that the renal disease is acute, and of recent origin. In the practical application of this rule you must be careful to ascertain that the kidney itself, and not the mucous membrane of the bladder, is the source of the blood. The most decisive evidence that the hæmorrhage is of renal origin is afforded by the fact of the blood, as seen on a microscopical examination of the urine, being moulded into casts of the uriniferous tubes.

In my next lecture I shall continue the subject of *contracted* Bright's kidney, and I shall then bring to your notice other examples of this form of disease.

## ORIGINAL COMMUNICATIONS.

### NOTES OF

## PRACTICE AMONG THE OUT-PATIENTS OF ST. BARTHOLOMEW'S HOSPITAL.

By JAMES PAGET, F.R.S.

Assistant-Surgeon to the Hospital.

### No. III.—ON SOME AFFECTIONS OF VOLUNTARY MUSCLES.

*Consequences of excessive exercise.*—The worst of these consequences has of late years been largely illustrated in essays on "Progressive Muscular Atrophy." Some of the cases of this affection seem clearly due to overwork of muscles, the atrophy beginning in those that are chiefly employed in the patient's daily labour, and gradually extending to the groups of muscles that are auxiliary to their actions. But it is of certain less serious and less considered consequences of excessive exercise that I now write.

Among these consequences the most frequent are muscular pains, which the patient usually describes as rheumatic. The shoulders, or the loins, or a limb, are complained of as the seats of constant, wearing, dull pains; they are weak and stiff, and unfit for work. The description is sufficiently like that of rheumatism; a history of exposure to cold is seldom wanting among out-patients; and the diagnosis and treatment of rheumatism are soon written down. Happily, the tired muscles, by their pain, generally secure their own repose, and their proper remedy.

One set of cases of this kind deserves especial mention, because they are, I think, very generally overlooked. I mean the cases of constant pain and weariness of the lower limbs associated with flat-foot. Among the numerous instances of this that I have seen in the out-patients' room, I do not remember one in which the patient was aware of his deformity, or did not give an account of himself that was calculated to

(a) The relation of urea to carbonate of ammonia is represented by the following formula, which shows that an equivalent of urea with two equivalents of water contains the elements of two equivalents of carbonate of ammonia— $N_2 H_4 C_2 O_2, 2H_2 O = 2N H_3, C O_2$ .

mislead. The common story is, that he has heavy aching pains in one or both of his ankles, or in his feet or soles; pains extending up the limbs, with weariness, and inability to go through his day's work. And all these or more he ascribes to cold or to some injury; he has no suspicion of a deformity, but his feet are *flat*. The soles are, perhaps, not everted; there may be no true valgus, but the feet look elongated, flat, and low, without insteps; the heels are too little prominent, the plantar arches sunken, the ankles thick, the astragalus, navicular, and inner cuneiform bones are below their right level. The pains complained of are those of the muscles and tendons, which are habitually overworked, in the task of keeping the body erect, when its proper bearings on its supports are disturbed; and the like pains may exist in any case in which the foot is habitually used awkwardly.

The treatment of such cases with orthopædic apparatus is generally sufficient for the relief of the pain; rarely so for the cure of the deformity. With such apparatus, and often without it, as the patients (who are generally between 16 and 20) grow older, the muscles and other structures become accustomed and more adapted to their undue action, and cease to be painful. Many men above 30 who are flat-footed make no complaint of it. The most flat-footed I have seen could walk thirty miles in the day without considerable fatigue.

In all these cases the pain is probably due to the impairment of composition, which ensues in the muscles during exercise, becoming, at last, greater than can be repaired in their ordinary repose, or when the general health is enfeebled. Pain of a much severer kind, but probably due to a similar condition of unrepaired change of composition, is sometimes consequent on excessive work continued for a comparatively short time.

A feeble lad, 17 years old, complained of pain in his right arm, especially in the lower part of the biceps, and in the flexors in the forearm. He held his arm bent at the elbow, and nearly straight at the wrist, and he said he could not move it; but he could do so, though feebly and slowly, as if the muscles, though not cramped, were stiff. All the joints could be moved in their full range, smoothly, and without pain. There was no swelling anywhere, but the biceps and flexor muscles felt unequally firm, and some parts of them felt nearly hard, like muscles with the cramp. There were no signs of constitutional disorder, and the only cause that could be assigned for his pain and other trouble was that he had been working for five months as a smith, hammering for ten hours a-day. Rest alone, I believe, cured him.

Sometimes a muscle after excessive exercise passes into a state of nearly fixed contraction, and abides long therein. Wry-neck may thus follow a great exertion of the muscles of the neck; and I have seen an elbow-joint stiff and motionless through rigidity of muscles ensuing in or quickly following a great effort. These cases are to be distinguished from those of rheumatism, which, in persons disposed to it, is often localised in a muscle shortly after it has been subjected to a too wide or violent action. And it would be very interesting to study the similarities between the stiffness and loss of power in exhausted muscles and the rigor mortis; they are much greater, I believe, than would be generally suspected.

*Some of the consequences of blows and the like injuries of muscles*—A blow on a muscle or on its nerve may be followed by complete wasting. For example:—I have seen a case of total atrophy of the abductor indicis and adductor minimi digiti, which followed a sharp and very severe blow in front of the anterior annular ligament.

After a severe injury to a joint, the muscles acting on it may pass into a state of fixed contraction, or may start into contraction at any effort to move them, whether actively or passively. The joint thus stiffened is likely to be regarded as one that has been wrongly treated; the fracture or the dislocation, if either have occurred, may be thought to have been left unredressed, and an incurable ankylosis may be talked of. But the stiffness of the joint is due to the muscles alone; and if, by giving the patient chloroform, they be relaxed and put beyond the influence of his will, the joint becomes at once naturally moveable, or nearly so. I have seen this condition at the elbow, the knee, and the hip; and I believe that I have known a similar affection of the muscles of the neck, causing temporary immobility of the head, after a blow on the vertex.

The patients are generally young persons, and the history of one may suffice; for all the cases were very similar in their results, however different in the accidents.

A boy, 10 years old, fell on his elbow and broke off the external condyle and adjacent portion of the articular end of his humerus. The arm was kept at rest on a well-padded angular splint, and union took place in the usual time, but the broken condyle remained prominent. He regained some power of movement of the elbow, but, apparently through neglect of the rules for using it which his Surgeon gave him, he gradually lost this; and when I saw him, five months after the accident, (a) the elbow was almost perfectly stiff at an angle of about 120°.

I took him into the Hospital, and he was put under chloroform, that the joint might be forcibly bent. But as soon as he was quite insensible the joint became easily moveable through an angle of fully 90°, and only just short of complete flexion and extension. As soon as he recovered from the chloroform the joint became as fixed as before in the extended position; it gradually became more stiff as he became more sensible and his muscles less relaxed.

The power of voluntary motion of the joint was gradually regained, with the help of frequent passive motion and the patient's own efforts.

The treatment here used will, I believe, usually be sufficient. Chloroform, which may first serve as a test of the state of the joint and muscles, may afterwards be used, to give opportunity for painless and free motion of the joint while the muscles are recovering. And their recovery may be accelerated by friction, warmth, passive motion to any extent that they will allow, and (which is far better) every possible effort of the patient's own will to move them.

*Enlargement of muscles.*—Inequality of size of limbs is far from rare, and in a large majority of cases it is due to defective nutrition of one limb, the other being of natural size. But in some instances the smaller limb is natural (judging by its proportion to all the rest of the body except its fellow), and the larger limb is overgrown. I have seen at least four such cases, and in all of them the enlargement of the limb appeared due to overgrowth of muscles, with, perhaps, a dilated or varicose state of their veins.

In the case of a lad 14 years old, who had been very active in running and jumping, the calf of the right leg was an inch and a half larger in circumference than that of the left, and had been so for more than a year when I first saw him. At times also during the year it had become yet larger, with painful swelling, and a sense of great tension in it, nearly disabling him from exercise. But when these severer symptoms (which appeared usually to follow over-use of the limb) had subsided, no change of shape or structure could be felt. The leg, especially at the calf, only looked more grown and older than the other, or at most its veins were larger after exercise than those of the other leg were.

Six months later, with the help of an elastic stocking and regulated exercise, all pain and discomfort had ceased to be felt, but the disproportion of the legs remained.

In other two cases the patients were respectively about 25 and 40 years old, and these also suffered occasional pain and weariness in the muscles of the large calf; but in neither of these was there any reason to regard over-exercise as the cause of the enlargement.

In another case, in a soldier 27 years old, there was great enlargement of all the muscles of the right arm and shoulder, and such fulness of all its subcutaneous veins, and such a feeling of weight and tightness when it hung down, that I supposed the axillary vein must be obstructed. However, with rest in the Hospital, and the occasional application of leeches, the muscles gradually diminished, and the veins became less filled; and finally, during an attack of scarlatina, they returned to nearly their natural state.

I have had no opportunity of dissecting a case similar to any of these, and can only guess that there is a real overgrowth of muscles, like that which occurs in cases of excessively large tongues. There has been no apparent enlargement of bones, or any other structures than the muscles and veins, in any of the cases I have seen; and in this respect they greatly differ from the cases of hypertrophy of one or more fingers or toes which Mr. Curling chiefly has described.

(a) In this alone the case was peculiar; in all the other instances that I have seen the stiffness of the joint occurred very soon after the accident, or was continuous with its immediate effects.

## ON A PECULIAR FORM OF LACERATION OF THE PERINÆUM DURING LABOUR.

By W. O. PRIESTLEY, M.D.

Physician-Accoucheur to the St. Marylebone Infirmary.

THE forms of laceration of the perinæum during labour usually described in obstetric works, are for the most part varieties of vertical tearing, the laceration taking a direction backwards, from vulva to anus, or outwards on either side. The only other described form of laceration which does not come under this category, is central laceration or perforation of the perinæum—the child passing directly through the centre or posterior portion of the perinæum. Instances of the last description are rare, but references are to be found to such cases in the works of Moreau, Simpson, Churchill, Ramsbotham, etc.

The object of this short communication is to call attention to the occasional occurrence of a horizontal or transverse form of laceration, not indeed necessarily extending to the cutaneous surface of the perinæum, or what has been called the "perinæum proper,"—but implicating the upper or mucous layer, which is situated internally, and yet constitutes an important element in the structure of the perinæum. Indeed the mucous membrane of the lower portion of the vagina, by its apposition to the upper surface of the cutaneous perinæum, so far adds to the thickness of the latter, that its capacity for dilatation is greatly increased, and the distension to which the perinæum is subject during labour is more adequately sustained. I may premise that before labour commences the vaginal orifice is situated less than half an inch anterior to the posterior fourchette or commissure, the fossa navicularis occupying the space between them. Thus, in first labours, as the head descends on, and lengthens the perinæum, two more or less well-defined ridges are found on its anterior free border. These ridges correspond respectively, the upper one to the usual attachment of the hymen or caruncula myrtiliformes, the lower to the fourchette or line of union between the mucous membrane and the skin. The fossa navicularis has then become effaced, the space between the vaginal orifice and fourchette lessened, and the free border of the perinæum bears some resemblance to a piece of thick felt cut obliquely, with the edge terminating its upper surface, projecting somewhat forward, and the edge of its under surface slightly receding. At the entrance to the vagina, where we find the upper or innermost ridge, the foetus encounters more resistance to its exit than in its subsequent progress when distending the posterior fourchette or commissure. Where the finger encounters the upper ridge, in fact, the strong fascial tube enclosing the contractile and mucous coats of the vagina terminates posteriorly, and is united to the superficial fascia of the perinæum by a less dense tissue. Thus at the orifice of the vagina, posteriorly, a circular resisting band presents itself, which ordinarily yields gradually before the pressure of the foetal head, but in exceptional cases, and especially if reinforced by an incompletely ruptured hymen, it offers considerable opposition to the completion of labour. In the usual course of events during first labours, the posterior margin of the vaginal outlet offers such resistance to the child's head, that the mucous membrane internal to it, is everted over it, and then the constriction gradually gives way, and labour is speedily terminated. As Dr. Churchill has observed, the mucous membrane while so everted is frequently fissured in a vertical direction, but the retraction after labour is over may cause it to be overlooked. Laceration to this extent may occur without passing round to the cutaneous surface of the perinæum, although some degree of external laceration seems to be far more common than has been formerly supposed.

In labours subsequent to the first, the two ridges I have described on the free border of the perinæum, are not nearly so distinct; the foetus encounters less resistance at the orifice of the vagina, and the perinæum becomes thinned out and stretched, so that it commonly presents a single sharp edge.

In the following case laceration of the mucous membrane, constituting the upper surface of the perinæum, took place horizontally along the resisting line indicating the orifice of the vagina, as if an incision had been made in a circular direction, severing the inferior extremity of the vagina from its usual junction with the perinæum.

Mrs. E., aged 20, a tall, slightly built person, with fair

complexion, and *nervo-sanguineous* temperament, who had previously enjoyed good health, was taken in labour of her first child on the morning of the 2nd of February, 1857. The pains occurred at regular intervals during the day, but no great progress was made until towards evening. Returning to her bedside about four o'clock, I found the pains much increased in severity, and the os uteri rapidly dilating. The foetal head passed without difficulty through a sufficiently roomy pelvis, and about seven o'clock began to press on the perinæum. As the external parts became subject to the pressure, I noticed that the ridge on the free border of the perinæum, corresponding to the termination of the vagina, was unusually firm, and had participated little in the general dilatation of the genital passages, while the vagina itself seemed to be narrower than usual, and tightly grasped the head of the child.

The pains being severe and constant I endeavoured to moderate somewhat the pressure of the child's head on the perinæum, and made copious use of unguents, hoping thereby to favour dilatation, but without much effect. The *anæsthesia*, which before had been imperfect, was deepened with no better result. The pains succeeded each other at short intervals with great expulsive power, and the head stretched the central portion of the perinæum to its utmost, without overcoming the resistance of its anterior edge. At last with a severe pain the mucous membrane gave way along the line of the constricting band, and a gush of blood followed. On the temporary recession of the head, I found a breach of continuity extending across the posterior wall of the vagina or floor of the perinæum, two inches or more in length, as if an incision had cut off the vagina posteriorly from the perinæum. The mucous lining was retracted upwards in a crescentic form, making a considerable wound, with blood oozing from its surfaces, and leaving the perinæum so denuded above, that it was reduced to one half its usual thickness.

My anxiety as to what further injury might follow was happily soon after terminated. With the next succeeding pain the constricting fascial band gave way, and the expulsion of the head and body of the child soon followed. The extrusion, however, was not effected without a partial vertical laceration of the weakened cutaneous perinæum, backwards towards the anus. Fortunately the patient was spared the agony she must otherwise have endured by being kept completely *anæsthetized*.

Convalescence afterwards was protracted beyond the usual time; the wound healed by granulation, and great pain was experienced during and some time after micturition from the urine trickling over the broken surface, until the plan was adopted of passing the urine through a sponge, which obviated this. Fully two months elapsed before all tenderness and induration of the perinæum were gone, and the patient was able to stand and walk with ease. She recovered at length perfectly.

In this case, the peculiar form of laceration was doubtless caused by the rigidity of the ring at the orifice of the vagina, the head stretching the somewhat narrow vaginal tube so far that its mucous membrane was fairly divided over the constricting fascia. It struck me, while watching with anxiety the events I have described, that had the resisting band not immediately given way, or some assistance been rendered after the internal laceration, the case would in all likelihood have been converted into one of the so-called central lacerations of the perinæum—the head and body of the child passing directly through the weakened perinæum, and posterior to the constricted vaginal opening. It seems no stretch of probability to suppose that in the instances where central laceration of the perinæum has occurred, it may have been preceded by events similar to those observed in this case. In some examples of central perforation, described by Dr. Ramsbotham, such a preliminary tearing seems actually to have taken place, and there can be no doubt that such an internal form of laceration previously occurring would strongly predispose to central perforation.

I have no sufficient experience of such cases as the one described above, to warrant me in drawing any general conclusions as to the frequency of their occurrence or their subsequent results. Slight transverse fissures in the mucous membrane at the line indicated I have noticed before in first labours, more especially when the head has been large or the vaginal canal somewhat narrow, but the case detailed is the only one I have met with in which this transverse form of laceration

was so extensive and so unmistakeable. From the silence of obstetric authors on the subject, one is disposed to think that its occurrence is not frequent, although, truly, from its internal situation, it may be readily overlooked, especially if the injury be of small extent. It is possible that in some of the cases of long convalescence in primipare occasionally met with, where there is tenderness and induration of the perinæum, pain in the upright position, and yet no external laceration observable, an injury of this kind may have been perpetrated unnoticed during labour. In my search after recorded parallel cases, I have been able to find only one which is analogous to that described. It occurs in Dr. Meigs's treatise on "Obstetrics," from which I extract the passage:—"I have recently seen a case of laceration, in which the wound commencing very near and within the inner third part of the left nymphæ, extended downwards and backwards, and then upwards in such a manner as to have cut the tube nearly half off, a very singular case, and which must have been near allowing the head to come through the perinæum." P. 83. Speaking of the above case with my venerable friend, Dr. Montgomery of Dublin, when lately in London on a visit, he informed me that this kind of laceration had occurred to him more than once in his practice, but he had not seen it frequently; and he further remarked that he had observed the internal laceration occur, without any injury whatever to the cutaneous perinæum. Mr. Baker Brown also informs me that he has seen a laceration similar to the one I have described, in which the hemorrhage was very considerable.

In the treatment of any future case where I have reason to suspect a transverse laceration probable, I should certainly deem it advisable to divide the constricting ring, rather than expose the patient to the risk of such an injury, followed, perhaps, by a vertical laceration, or, worse, by a perforation directly through the perinæum. In this instance the expulsion of the child speedily followed the laceration, and any further interference was unnecessary,

31, Somerset-street, Portman-square.

# ON THE MORTALITY OF THE METROPOLIS IN THE SUMMER OF 1857,

INCLUDING A NOTICE OF THE DIARRHŒA EPIDEMIC.

By J. J. FOX, Esq.  
Fellow of the Statistical Society.

(Concluded from page 245.)

THE weekly returns of the Board of Health, published under the careful supervision of Dr. Conway Evans, furnish some very interesting information, although far too incomplete to rely on in the absence of other data. We may, however, gather from them, what might not perhaps have been anticipated *a priori*, that the maximum of deaths does not correspond with the maximum of new cases. The first occurred, as we have seen, in the last week of July, or that ending on the 1st of August; whereas the greatest number of new cases of diarrhœa did not occur until two weeks later, or the week ending August 15, from which time they rapidly declined. This agrees with what has been observed in the epidemic invasions of cholera, that in their progress they become of a milder character, so that there is an interval during which the cases are actually increasing in number, while the deaths are becoming fewer. While, as we observed just now, the curve representing the deaths declines very gradually, compared with the abruptness of its rise, the same is not the case with the curve representing the new cases of diarrhœa. In it the branch of the curve succeeding the maximum corresponds tolerably with that which precedes it. The inference may perhaps be, that the slowness in the decline of the deaths, as compared both with their own rise and with the decline of new cases, is due to the numbers being kept up by deaths ensuing at longer distances from the attack.

That meteorological causes have had great influence on the epidemic it is impossible to deny, when we examine the character of that week which presented the maximum of new cases, and subsequently to which the epidemic declined. It was marked by rain almost every day of the week, and by

very heavy thunder-storms, with hail and large quantities of rain on the Thursday and Friday. As a consequence of this electric disturbance, the wind, which for seven weeks had been in the south-west, became north-east through the following week. Whatever be the mode of its action, there must have been a connexion between this great atmospheric change and the decline of the epidemic diarrhœa.

## V. LOCAL DISTRIBUTION OF DIARRHŒA.

An inquiry into the local distribution of the deaths from diarrhœa during the past summer leads to the conclusion that they were distributed among the five divisions of the Metropolis, in proportions not greatly differing from the proportions that the divisions bear to the whole in population. I subjoin an approximate estimate of the per-centage of total population resident in each division in the middle of 1857, and place by it the per-centage of deaths from diarrhœa:—

	Population.	Deaths from diarrhœa.
Western . . . .	16	18
Northern . . . .	22	19
Central . . . .	15	14
Eastern . . . .	21	23
Southern . . . .	26	25
	100	100

It will be seen that the eastern and western divisions had a larger share of the deaths than their population warranted, while the others had less; and also that the northern division is the one in which the share of diarrhœa deaths is the furthest from coming up to the proportion it bears in population.

If we attempt to go into further subdivisions, and estimate the prevalence of diarrhœa in the districts of the Metropolis, the difficulties that interfere with an accurate estimate of their comparative mortality become much augmented. The complication introduced by the presence of large Hospitals cannot be corrected, as it can when we treat of "deaths from all causes" in the aggregate. It is not probable that many enter our Hospitals to be treated for diarrhœa; and yet when a number of invalids, suffering under other diseases or from accidents, are collected together, many will doubtless fall victims to diarrhœa at a time when it is epidemic, and thus indirectly swell the returns of a district in which a large Hospital is situated. Besides this source of fallacy, our estimate of population, which at all times is only approximate, becomes far more uncertain where a smaller mass of population is concerned. Nevertheless, so great are the differences between the estimates of the mortality from diarrhœa in the different districts of London, that, allowing the largest possible margin for error, they indicate very striking differences between one district and another. In the City of London it was only 32 deaths to 100,000 of population, in Camberwell 51, and St. George's, Hanover-square (in spite of its Hospital), 59; these three being the only instances in which it was less than 60.

Five districts had a mortality between 60 and 70, viz.:—Holborn, Pancras (with a Hospital), Hampstead, Hackney, Clerkenwell.

Four, between 70 and 80, viz.:—St. James Westminster, Islington, Bermondsey, Newington.

Eight, between 80 and 90, viz.:—Lewisham, Lambeth, East London, Strand (with a Hospital), Bethnal-green, Greenwich (with a Hospital), Shoreditch, Wandsworth.

Five, between 90 and 100, viz.:—St. Martin-in-the-Fields, Marylebone (with a Hospital), Stepney, St. George South-west, St. George in the East.

A mortality from diarrhœa above 100 in 100,000, or 1 to every 1000 of population, is estimated to have occurred in

West London (with a Hospital), Rotherhithe, Chelsea, Kensington (with Hospitals), St. Giles Westminster, St. Saviour and St. Olave (with their Hospitals), St. Luke, Whitechapel (with a Hospital), Poplar.

In the last-mentioned district the mortality was highest, and reached 123, no small contrast to the 32 that died out of the same population in the City. If the population of any district has increased more slowly in the last six years than it did between 1841 and 51, then these numbers are lower than the correct mortality; if, however, the increase of population has been greater than that assumed, these numbers are too high. The second of these qualifications, doubtless, applies to several of the districts, but the limits of the error intro-

duced by it would form but a small fraction of the wide differences between the mortality of one district and another.

#### VI. COMPARATIVE MORTALITY OF THE DIVISIONS OF THE METROPOLIS.

If we estimated the mortality in the five divisions of the metropolis without any correction for outlying workhouses and for the deaths in hospitals, lunatic asylums, and prisons, we should not obtain results on which any reliance could be placed. Making these needful corrections, however, and assuming the population of each division or group of districts to have increased since 1851 in the same ratio as it did between 1841 and 51, we obtain the following numbers for the mortality of the summer of 1857:—

Western Division	. . . . .	496
Northern Division	. . . . .	500
Southern Division	. . . . .	506
Central Division	. . . . .	549
Eastern Division	. . . . .	614

The mortality of the whole metropolis having been, as stated in the beginning of this paper, 534, we find the same law subsist that I noticed in my last two papers, viz. that the Western, Northern, and Southern divisions are more healthy than the average of London, the Central and Eastern less so. With regard, however, to the Central division, it is well to remark, that while in the winter it had 72 deaths in 100,000 more than the average of London, and in the spring, 44, it has during the season we are considering an excess of only 15 deaths.

The difference between the mortalities of the most healthy and least healthy divisions of the metropolis has this summer been 118; in other words, to a population of 100,000, 118 more persons have died in three months in the Eastern districts than died in the Western. If we look only to those diseases, the local distribution of which is given in the Registrar-General's Reports, we find the same high mortality of the Eastern districts confirmed. They form, probably, about 21 per cent. of the population of London, and yet within their borders occurred 22 per cent. of the small-pox, 23 per cent. of the diarrhoea, 26 per cent. of the typhus, 29 per cent. of the scarlatina, 33 per cent. of the whooping-cough, and 40 per cent. of the measles. Who, indeed, can gainsay the need of sanitary action, and who can say that statistics do not furnish evidence of a case for the interference, guarded by wise precautions, of Government, whose duty it is to protect the lives and happiness of the masses?

Stoke Newington.

### ON GUNSHOT WOUNDS OF THE EYE.

By W. WHITE COOPER, F.R.C.S.

Ophthalmic Surgeon to St. Mary's Hospital, &c.

(Concluded from page 248).

*Penetrating wound of eye.—Atrophy of globe.*—Lord C. (whose case has been already mentioned) was shooting with a party in a turnip-field nine years ago, when one of the gentlemen pushed too much forward; at that moment Lord C. fired at a bird. There were many boulder stones in the field, and it is supposed that a shot glanced, for though the distance was full 150 yards, this gentleman was struck in the left eye, the sight being immediately lost. He underwent severe treatment to subdue the inflammation which followed, and was confined to his room two months, suffering great pain. This pain continued in the brow with greater or less severity for a year and a-half, and then gradually ceased. The eye diminished in size, but has been quiet for seven years, except at changes of weather. I saw this gentleman, November 17, 1857. Condition of the eye:—Globe soft and about one-third less than the other eye. Colour of sclerotic brownish, circumference of cornea one-fourth less than that of the right eye, and squared off towards the lower and inner corner. Nearly in the middle of the lower edge there is a white cicatrix, marking the seat of the wound, and to this all the fibres of the iris converge, there being no trace of pupil; anterior chamber obliterated; iris naturally grey, now greyish olive. The sclerotic presents two marked puckers or depressions tending towards the cicatrix. Many small dull red vessels ramify over the eye.

This gentleman mentioned that the neuralgia from which he suffered so long appeared to yield at length to repeated small blisters on the temple, recommended by Mr. Dalrymple.

We occasionally see unusual changes take place in eyes which have received injury from shot. The most remarkable that I have witnessed is the formation of a peculiar deposit in the anterior chamber, of precisely the tint of yellow ochre. I have always found in connexion with this a tendency to

spontaneous bleeding in the eye, fulness and hardness of the globe, and complete disorganisation of the iris. I have not yet had an opportunity of satisfying myself as to the precise character of this deposit, and in one case only has this condition presented itself; the particulars are as follow:—

*Gunshot wound.—Shot lodged in eye.—Yellow deposit.*—In May 1857 I was consulted by a gentleman under the following circumstances. In January 1854, he was one of a party woodcock shooting, when a glancing shot entered his left eye, and immediately extinguished sight. There was some bleeding from the eye, and considerable extravasation of blood under the conjunctiva. His eye was bound up with a handkerchief steeped in cold water, and on reaching home he was placed in bed feeling sick and faint with pain in the eye and brow; a cold poultice was applied to the eye, and active antiphlogistic treatment employed; nevertheless the eye remained in a state of inflammation for nine weeks, despite of an active mercurial course. The redness and intolerance of light gradually passed away, leaving the globe hard, tender, and subject to neuralgia, which has been a source of torment to him ever since.

The condition of the eye when I saw it was as follows:—The globe perfectly hard and tense, and traversed by dark vessels. The iris bulged forward so as to encroach considerably on the anterior chamber, and of a dark olive green; pupil contracted, and occupied by lymph; in the lower part of the anterior chamber a dark stain and small coagulum of blood. Around the inner circle of the cornea was a singular yellow line, as if the iris had been encircled with a frame; on the inner surface of the cornea there were towards the lower part several small spots of a similar colour; the cornea itself was very tense. The chief complaint made was of neuralgia, and of occasional sharp dartings, like needles being thrust into the eye.

The sight of the right eye was as yet unaffected, nevertheless I thought it proper to suggest excision of the damaged eye, as that alone would relieve the neuralgia. My proposition was not acceded to, and I did not see the patient till early last August; he then stated that his eye had remained in much the same state, except that two or three times after violent neuralgia, and a sense of bursting, blood had appeared in the eye, and it had of late become much more yellow. Such indeed was the case; the whole of the posterior surface of the cornea was covered with this yellow deposit; the circle was still visible, but little of the iris itself could be seen, and that little appeared to be marked with deposit also: it was irregularly scattered over the inner surface of the cornea, in some parts in distinct patches, in others as if lightly smeared, or as if the colour had run.

I have seen one other case in which a similar condition followed an operation with the needle, and I believe that it invariably indicates thorough disorganization of the eye.

A few words remain to be said on the management of gunshot wounds of the eye.

A Surgeon summoned to a case of this description may expect to find the patient, and those about him, in great alarm and distress, and may have some difficulty in obtaining a correct account of the accident.

The first thing to be done, having gently and carefully cleansed the eye, is to make a full and satisfactory examination to ascertain the precise nature and extent of the injury, and to obviate, as far as possible, the necessity for subsequent

disturbance of the eye; for as each day will increase the irritability of the organ and the intolerance of light, frequent elaborate examinations are most pernicious. If there be a sensation of a foreign body under the upper lid, it will be proper to ascertain whether anything has lodged there. Should there be a wound with fibres of the iris hanging out, they should be snipped off with fine scissors. The lids should then be closed and secured with a strip of soft adhesive plaster, (a) to render them as motionless as possible. The subsequent measures will of course depend on the symptoms which present themselves, but the surgeon should insist on the patient remaining absolutely quiet, and on the strictest antiphlogistic treatment being adhered to. In many cases three months, and even more, elapse before the eye becomes quiet, and it is often difficult to prevent a patient transgressing the rules laid down during such a long confinement; but a judicious surgeon will carefully watch the progress of the eye, handling it as little as possible and in the most gentle manner, and modifying his treatment according to the progress made towards convalescence. If there be reason to suspect that the shot is in the eye, railway travelling, and all vibrating or jolting should be avoided, lest the irritation in the eye should be lighted anew by the foreign body being displaced.

The question may present itself, What course should be pursued if the shot should lodge in the crystalline lens? I do not hesitate to recommend extraction of the lens; for sooner or later, if let alone, the shot will be loosened by the lens being absorbed, and will set up serious inflammation. A most instructive case, illustrating this point, has been mentioned by Dr. Jacob of Dublin, in a valuable paper on "Foreign Bodies in the Eye." (b) A fragment of a copper cap had passed through the pupil and lodged in the crystalline lens where it lay, retaining its brilliancy for two or three years, without causing pain or mischief. But after a further time the lad again applied to Dr. Jacob, and now the copper cap had disappeared, and the anterior and posterior chambers were filled with blood as if from recent injury. The metallic fragment was nowhere visible, and had probably fallen to the bottom of the eye. The inflammation excited, destroyed the organ.

The most tormenting and persistent symptom in many cases of gunshot wounds of the eye is neuralgic pain affecting the brow and side of the head; this remains long after active symptoms in the eye have subsided, and is very obstinate. The treatment which I have found most efficacious is counter-irritation on the temple, either by means of an issue, a seton, or repeated blisters.

Should an eye continue in a state of irritation, and weary the patient month after month with the miseries of neuralgia, we should be justified in recommending excision of the globe. This at once puts an end to the pain, and restores the sufferer to the enjoyment of health. I have taken some pains to ascertain if gunshot wounds of the eye often cause sympathetic irritation, threatening the sight of the other eye. An instance has recently presented itself at Moorfields, and the injured eye was removed by Mr. Wordsworth; but so far as my own experience goes, such cases are happily rare.

19, Berkeley-square.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### ST. BARTHOLOMEW'S HOSPITAL.

#### PECULIAR AND VERY RARE FORM OF DESTRUCTIVE INFLAMMATION OF THE CORNEA. —EXTIRPATION OF BOTH EYES.

(Under the care of Mr. LAWRENCE.)

Ann Price, aged 25, a domestic servant, was admitted on January 2. She had been sent to St. Bartholomew's from the Fever Hospital, where she had been an inmate for two days only, having been discharged because her disease presented no features of specific fever. She was a thin, pale,

very cachectic woman. Her left eye was very prominent, and the conjunctiva in a state of chemosis, much swollen and very florid. The cornea was opaque and yellow like wash leather, and beginning to slough. There was no purulent or other discharge. She complained of a most severe frontal headache. The account she gave was that her eye had been inflamed only about ten days, and that during this time she had suffered most severe pain in the temple. She had been out of health, she said, ever since the summer, when a severe diarrhoea had much reduced her. Her eyes had also, she thought both of them, been more prominent since that illness than formerly, and her friends had also remarked upon the same circumstance. She had, however, been able to remain at her place until the present attack in the eye, at the onset of which the febrile disturbance had been so peculiar that the case had, as observed above, been mistaken for one of fever, and she had consequently been sent to the Fever Hospital. There was nothing amiss with the right eye, excepting that it was noticed to be unduly prominent.

The destruction of the cornea in the left having rapidly become complete, and the eye being totally lost, Mr. Lawrence determined to remove the globe. This was done by the usual operation about three weeks after her admission. At the time the eye was very prominent, and surrounded by swollen and everted mucous membrane. The iris and pupil were covered by layers of tough yellow lymph. During the operation nothing was observed to account for the extreme prominence of the globe; there was no abscess or tumour behind it. The globe on examination appeared to be healthy as regards all its structures excepting the destroyed cornea. No suppuration had occurred within it. Much relief to the frontal headache, etc., was obtained by the operation, but the conjunctiva still remained cedematous, and much swollen, so as to evert the lids somewhat.

About a week after the operation the right eye was attacked by disease exactly similar to that which had destroyed the left. The conjunctiva became swollen and dry, and the cornea dull. The latter was rapidly covered by a thick crust. On taking off this scab, a few days after its formation, the cornea was seen to be still perfect in form, though wholly opaque, and roughened and dry on its surface. It ultimately sloughed, and came away, exposing the whole iris.

Extirpation of this globe also having been decided on, the woman was again brought into the theatre on Saturday last (March 6). A scab of yellow lymph occupied the centre of the much protruded eye, concealing the iris, etc., and all around was a roll of red, dry, very tumid conjunctiva. After removal, it was found, as had been observed in the other, that the vitreous, retina, choroid, etc., were all apparently healthy, the disease being confined to the anterior parts.

*Mr. Lawrence's Clinical Remarks.*—Mr. Lawrence stated after the operation that this case, as far as his experience went, was unique; at least such had been the fact until within the last few weeks. About a fortnight ago he had seen, in consultation with Mr. Alexander, a lady somewhat past middle age, whose eye presented an exactly similar condition, and had, like those of the poor girl just removed from the theatre, been wholly lost by destructive inflammation of the cornea, unattended by apparent cause. In both cases the peculiar thrusting out of the globe had been observed, and in neither was there anything to account for it beyond the swollen condition of the cellular tissue of the orbit. In neither had there been any purulent discharge whatever from the conjunctiva, and in neither had suppuration taken place either in the globe or the orbit. The difference in the age and circumstances of the two patients made it evident that the disease did not depend on any special habits of life or particular period of life. In the girl's case, it was also remarkable that the second eye had been attacked so long after the first. She had meanwhile been fed up, had acquired a good appetite, and was in greatly improved health. Mr. Alexander had agreed with him that he had never before witnessed an example of similar disease.

We may add with regard to the treatment pursued, that it had consisted, as far as medicines are concerned, in the endeavour to mitigate pain. The headache had been so severe that at one time it was necessary to keep ice in a bladder applied to the forehead. Morphia had also been prescribed, and on one occasion a few leeches had been resorted to. A liberal diet had been allowed throughout.

Should any be inclined to name these, happily, very rare

(a) I can strongly recommend that spread on soft kid leather prepared by Ewen, Jermyn-street, St. James's.

(b) Dublin Medical Press, December 9, 1846.

cases by the now so fashionable designation of "diphtheritic," we must ask them to bear in mind that the exudation spoken of covered the cornea only. The conjunctival surface was throughout almost dry, and destitute of secretion.

## THE ROYAL OPHTHALMIC HOSPITAL.

### CASES OF GONORRHOEA AND GONORRHOEAL OPHTHALMIA IN YOUNG CHILDREN.

(Under the care of Mr. Critchett.)

Two cases of gonorrhoeal ophthalmia in young children are now under care at the Moorfields Ophthalmic. The patients are sisters, the one aged 6 and the other 4. The eldest was brought to Mr. Critchett three weeks ago, on account of purulent ophthalmia of the left eye, and her mother at the same time asked attention to a severe inflammation of her genitals. The state of the eye was exactly that of gonorrhoeal disease, the chemosis being great, the discharge profuse, and of a greenish yellow colour, and the lids much swollen. The inflammation of the vulva was also more acute than is generally seen in the bastard disease of infants. The mother stated that a lodger who slept in the same room as the girl was known to have "the disease," and she feared the child had caught it by using a soiled cloth. The case was prescribed for, after a careful investigation of the facts, as one of true gonorrhoea of the eye. Alum water was ordered for hourly use, and nitrate of silver drops three times daily. To secure the full use of the latter, the child was to attend each morning, and have them put in by the House Surgeon. A day or two afterwards the other eye became affected; and three days later the younger sister was brought, suffering from exactly the same combination of symptoms. Both eyes were affected in her case also, and so severely, that for a time it was much feared that the cornea would slough. At present the four eyes are all recovering, danger to the sight being fairly past. Local measures have alone been employed. In both children the gonorrhoeal discharge still persists, though somewhat abated by treatment.

The younger child, there is little doubt, in this instance contracted the disease from her sister, as they slept together, and were much exposed. Respecting the elder one no suspicions have ever entered her mother's mind as to improper treatment, and it would of course, under circumstances in which the truth could scarcely by any possibility be arrived at, have been most ill-advised for the Surgeon to suggest them. It is impossible, however, that they should not be felt. We quote the case chiefly because it shows how liable young children having true gonorrhoea are to have the eyes infected. It is well known that the spurious disease often exists for months together; that it is common amongst the most neglected children, and yet how almost never do we find the eyes suffer! (a) This is doubtless because the discharge in these cases is non-contagious, and we have in the circumstance a means of diagnosis which will occasionally be very useful. In further corroboration of its value we may mention a case now under Mr. Hutchinson's care at the Metropolitan Free Hospital. A child of two has a discharge exactly resembling true gonorrhoea, and also suffers from commencing purulent ophthalmia of the left eye. The discharge is of a month's duration, but the eye was first affected only two days ago. The mother states that the child was subjected to ill-treatment by a young man, who has been convicted of the offence, and sentenced to a lengthened period of imprisonment.

### MEDICO-LEGAL QUESTIONS IN REFERENCE TO INFANTILE GONORRHOEA.

Cases of purulent discharge from the genitals of female children, occurring under circumstances more or less suspicious, constitute some of the most disagreeable and perplexing with which the surgeon has to deal. On the one hand, there is no doubt that the vast majority of such are

(a) In reference to the non-contagiousness of the common form of infantile leucorrhoea, the writer has, by running through his note-books of the out-patients' practice at the Metropolitan Free Hospital, obtained the following fragment of evidence. During the last three years he has treated sixteen cases of this affection in female children varying from the age of ten months to that of six years. In several the disease was very severe, and in most it had lasted a month or more. In none of these was there any suspicion of criminal contagion. In none did more than one child in a family suffer, and in no single instance did any inflammation of the eyes occur.

merely instances of an idiopathic non-specific affection, and on the other, it is perfectly certain that true gonorrhoea may be, and sometimes is, transferred by contagion to children of the most tender age. How to distinguish between the two is the question. Not a few innocent men, the victims of circumstantial evidence, and of mistaken diagnosis, have undoubtedly been sentenced to punishment for abominable offences of which they knew nothing; and notwithstanding the earnest labours of several modern surgeons to set the matter in a clearer light (amongst whom we must make honourable mention of Mr. Wilde, of Dublin) we cannot feel confident that similar mistakes may not again occur. On the other hand, care must be had that by a too sweeping denial of the specific nature of these cases, the ends of justice be not occasionally defeated. Even of the cases of true gonorrhoea in children, it is to be admitted that in most the disease has been conveyed accidentally by cloths, sponges, and the like, and not by any sexual contact. Not unfrequently, also, it is contracted from women with whom the children have slept. But when full allowance has been made for these cases, still there most undoubtedly remains a class in which the disease is due to voluntary and criminal acts. Nor does the admission that the fact is so, involve a charge against humanity of so black a dye as might at first sight appear. A certain most absurd, but very prevalent vulgar belief, transfers to the head of a debased selfishness, acts which would otherwise be attributable to yet more profound depravity, and at the same time explains why it is that, in a large majority of cases, the guilty person is found to have been at the time of the commission of the crime the subject of venereal disease.

Several cases of much importance in reference to these questions have recently come under notice in the Metropolitan Hospitals. In one, the evidence upon which a conviction was obtained, was supplied by the House-Surgeon to King's College Hospital, and consisted in the fact that spermatozoa had been found in the child's vulva. This was, of course, unanswerable, and, as it was established by the testimony of two observers, was very properly allowed to have its due weight. It is much to be desired that this test were more constantly resorted to at the time of the first examination of the child.

We have above mentioned the statement of the mother of Mr. Hutchinson's patient suffering from gonorrhoeal ophthalmia as to a criminal prosecution having been instituted.

This statement Mr. Hutchinson found, on subsequent inquiry, to be correct, and, as the case is of considerable medico-legal interest, we subjoin its main facts. On the evening on which the offence was alleged to have been committed, a woman with whom the prisoner cohabited was in her confinement. The mother of the child was attending to her, and left the child, with several others but little older, under the care of the prisoner in an adjoining room. These children, as well as the patient herself, were too young to give any evidence as to what took place. On the day following (a Tuesday) the mother noticed that the child was red and sore about the genitals. The appearance of irritation increased, and on the third day a discharge had set in, which on the fifth had become profuse. On the Saturday, for the first time, the child was shown to a druggist, who said she was suffering from "the disease," and, on account of the suspicions then excited, late in the evening of the same day an experienced Surgeon (Mr. Comley, of High-street, Whitechapel) was requested to examine her. The limitation of the disease to the vagina and labia, the severity of the inflammation, and the character of the discharge, induced Mr. Comley to give a confident opinion that the disease was true gonorrhoea. The man was now apprehended, and it was found that he was suffering from gonorrhoea, which he said was of a month's duration, the discharge being still copious. No microscopic examination of the discharge from the child was made, too long a time having elapsed to give any chance of spermatozoa being detected. At the trial Mr. Comley deposed on oath to the specific nature of the disease, and to his belief that it had been communicated by the voluntary act of the prisoner. The latter protested his innocence, and pleaded that the communication had probably been accidental, the child having used the same chamber utensil as himself. As has been stated, those present at the time could give no account of what had passed. The mother of the child, however, stated she had gone into the room on account of hearing her cry; she had not, however, noticed anything particular as to the condition of the prisoner

or his dress. A verdict of guilty was returned, and sentence of imprisonment, with hard labour for two years, was pronounced. The trial took place about three weeks ago, at the Clerkenwell Sessions House.

The subsequent occurrence of gonorrhoeal ophthalmia has fully substantiated the Medical evidence given in this case as to the specific nature of the child's disease, and there is scarcely room for a reasonable doubt that the contagion was in some way or other supplied by the prisoner; as to whether it were accidental, or the consequence of a criminal act, opinions will, however differ. Whoever is acquainted with the careless and filthy habits of many of the poor will find no difficulty in admitting that, after all, the prisoner's account might possibly have been true.

### HOSPITAL NOTES.

#### LARGE CALCULUS IMBEDDED IN THE PROSTATE GLAND.

We have mentioned recently several cases in which urinary calculi had become lodged in the prostate gland, and from their peculiar position occasioned symptoms somewhat different from those in which the stone remains free within the bladder. Among such symptoms, for reasons very apparent, is incontinence of urine. Another example is afforded by a patient on whom Mr. Stanley recently performed lithotomy. The poor fellow not only had incontinence, but several urinary fistulae had been left by abscesses which had formed in the perineum. He had suffered from symptoms since early childhood, his present age being 22. That the calculus was imbedded in the prostate was evident before the operation, because the sound grated over its surface before entering the bladder, and the finger introduced into the rectum readily detected the concretion. At the operation it was found to be of the size of a small chestnut, and to have been moulded in a cavity in the gland. In the bladder was a second stone which was quite free. The age of the patient at the time the symptoms commenced of course makes it all but certain that the original stone was a urinary one. No doubt it had at some time slipped into the prostatic urethra, and there being retained had gradually increased in size, and worked for itself a bed in the substance of the gland. Prostatic concretions are never met with before the age of puberty. The size, etc. of the stone itself also support the conclusion indicated. The man, we should add, has made a good recovery, and although he still remains in the Hospital, has for some time been out of all danger.

#### DIPHTHERITIC OPHTHALMIA.

We believe we may state that no cases deserving the specific designation of diphtheritic ophthalmia have as yet been met with at the Moorfields Hospital. Cases in which pustules are associated with the patchy exudation of flakes of adherent fibrin have, of course, been seen, but they are by no means new to the ophthalmic Surgeon, nor have they probably anything peculiar (as to kind) in their nature. A few cases of patches of fibrin on the surface of one or other palpebral conjunctiva have also been seen, but in none has the coating been extensive. Anything like an example of the formation of a cast of the ocular and palpebral mucous membrane, or even of any extensive tract of one, we have as yet neither seen nor heard of in London practice.

#### THE PHOSPHATE OF ZINC.

The phosphate of zinc has been for a considerable time employed as a nerve tonic by Dr. Barnes in his practice at the Metropolitan Free Hospital and on board the Dreadnought. It is generally prescribed in combination with free phosphoric acid, and Dr. Barnes is inclined to think that he has obtained from it better effects than could have been had from either of the components given alone. The dose is from two to five grains. The cases in which it is recommended are those of epilepsy, and other nervous disorders occurring in enfeebled persons, and it is thought to be especially useful after exhaustion of the nervous system from over-excitement. Although the merit of introducing the salt in question into notice belongs, we believe, to Dr. Barnes, yet probably many of us have long ago been in the habit of prescribing together sulphate of zinc and phosphoric acid, which would come to about the same thing.

#### WOUNDED ARTERY TREATED BY PRESSURE—EXTENSIVE SLOUGHING.

The case of a man now under the care of Mr. Cock, in Guy's, affords a striking illustration of the ill effects of the use of severe local pressure for the restraining of arterial hæmorrhage. He is a cow-doctor, and was bleeding a cow with the ordinary fleam, when the instrument slipped and entered his right hand near the wrist, at the back of the carpo-metacarpal joint of the thumb. The bleeding was very profuse at the time, but it was arrested by some tight dressings which were applied. As, however, it again returned whenever the dressings were removed, they were finally allowed to remain on for a week, and then, as the hand was greatly swollen, the man was sent to Guy's Hospital. When admitted, Mr. Poland at once removed the dressings, and the bleeding being again profuse, he enlarged the wound and secured the ends of the injured radial artery. Extensive sloughing of the wound however followed, and so unhealthy was its condition, and so severe the constitutional disturbance, that in spite of the freest support, it appeared for a time doubtful whether the man would live through it. His age, 69, has undoubtedly exercised some influence in favouring the morbid processes, but it is to be stated that, for his age, he is remarkably vigorous.

#### ANÆMIA FATAL WITHOUT ORGANIC DISEASE.

Two cases of much interest, as examples of fatal anæmia without any discoverable visceral disease, have recently been brought under our notice. The patient in the first was a young man under Dr. Bristowe's care in St. Thomas's Hospital, the second being a girl under that of Dr. Leared in the "Great Northern." The symptoms and course of the malady had in Dr. Bristowe's case borne a very close resemblance to those which existed in one which we published in detail two years ago from the Victoria-park Hospital. In the last the man was a Jew, and although all proper influences were used, consent to an autopsy could not be obtained. He had not displayed during life the slightest trace of pigmentary discoloration. In the two cases just referred to post-mortem examinations were had, but in neither were the supra-renal capsules found diseased. The form of cachexia present in these cases is often so much like that of "Addison's disease" that suspicions as to the state of the capsules in them has very naturally been excited. Further than this, however, there are clinical facts recorded, which make it very probable that in rapidly disorganising changes of those organs the patient first becomes sallow and anæmic. True bronzing is a subsequent change, and requiring a long period for its production. Dr. Habershon has at present an interesting case under his care in Guy's, in which a man, aged 21, is the subject of most severe and increasing anæmia. He has been four months an in-patient, well fed, and taking iron with tonics in various combinations, but the condition persists, and will probably end fatally. It must be noted that he had only been out of health a month when admitted, and there was at first a tendency to hæmorrhagic purpura. No pigmentary change in colour of any part of the skin has been noticed. It is of course exceedingly doubtful whether the capsules are diseased in this case. Many instances on record, in addition to the two just mentioned, prove that such a state may exist, and end fatally, while they are quite sound. In a case of this kind which died under Dr. Owen Rees's care about a year ago, and which we formerly mentioned, they were, however, found extensively diseased.

#### TRACHEOTOMY IN CHRONIC DISEASE OF THE LARYNX.

Dr. Peacock has at present under his care in St. Thomas's a young woman on whom tracheotomy was performed about six months ago, under urgent circumstances of laryngeal obstruction. The nature of the disease was not very evident, but it was suspected to be syphilitic. The relief to the breathing has been very great, and the patient is now in pretty good health. She is, however, as yet quite unable to do without the canula, which has been worn ever since. It is not easy in this, as in not a few others, to explain satisfactorily the cause of the continued obstruction, since there does not appear to be any progressive disease, nor was there any reason to think that extensive ulceration of the larynx had taken place. We have several times before had to advert to similar cases. One patient in particular still occasionally

presents himself at Guy's Hospital, on whom Mr. Birkett performed tracheotomy three years ago, and who, although now in good health, has never been able to dispense with the canula. Dr. Peacock's case adds another to the list in which life has been saved by the prompt performance of this operation.

## Medical Times & Gazette.

SATURDAY, MARCH 13.

### SELF-SUPPORTING DISPENSARIES.

In the first number of the present volume we drew attention to some of the existing abuses of Medical Charities, and to the proposal of providing a remedy by the establishment of Self-supporting Dispensaries. So much interest has arisen in the question, both on the part of the Profession and of the public, that it appears desirable to recur to the subject.

The idea of establishing institutions where those classes of the poor, not absolutely destitute, may receive competent Medical assistance on the payment of a small sum, is by no means a new one. Several Dispensaries founded upon this principle have met with most remarkable success. There are now lying before us a number of Reports presented at the successive annual meetings of the governors of the Coventry Provident Dispensary, an institution which appears to have been in flourishing circumstances for the last twenty-six years, and to continue still in a prosperous condition. At the last annual meeting held in May 1857, it is reported that the number of free members had nearly doubled since 1853, the funds having been benefited in the same proportion; and that 2654 persons had been under the care of the Medical officers during the past year. No less than £646 were received from the free members, which sum, together with about £100 more derived from subscriptions, was amply sufficient to defray the current expenses, including the payment of £80 to the Dispenser, and £431 to the Surgeons of the Institution.

Among the Resolutions adopted at the meeting is the following, which so completely describes the objects and tendencies of a well-regulated Self-supporting Dispensary, that we quote it entire:—

"That it is the opinion of this meeting that the Provident Dispensaries—the object of which is to provide Medical attendance in sickness from a fund supplied by the poor themselves—are calculated to save the poor from getting into debt, from resorting to the parish, and from injuriously delaying necessary Medical advice; and that they have a direct tendency to foster provident habits, self-reliance, and self-respect, and are therefore particularly deserving of the support of the public."

Now it certainly appears that these poor people of Coventry have set a very noble example to persons of like condition throughout the country; for by their voluntary contributions to the funds of the Dispensary they provide for themselves adequate and prompt Medical assistance in the hour of their

suffering, without being compelled to solicit Dispensary letters as a matter of charity, or to throw themselves upon the mercy of the Poor-law authorities. The Medical officers, too, appear to receive a fair remuneration for their services. They are paid in proportion to the number of cases they attend, and to the amount of surplus which may exist after paying the other current expenses of the establishment.

It is well known that in many parts of the provinces of England, and especially in the rural districts, voluntary associations are formed among poor people for the purpose of providing for themselves Medical attendance in case of sickness. As in the case of the Provident Dispensaries, they thus secure the benefits of Medical advice at a very moderate cost, and without begging for it as a matter of charity, while the Medical practitioners of the district are enabled to make some addition to their incomes by the contributions of the members. But there are many objections to these clubs: the meetings of the ruling Committee at public-houses, the constitution of this Committee confining the government of the clubs to uneducated men, and the calculations on which they are founded being so erroneous as to lead to frequent bankruptcy, are all objections which have proved very serious obstacles to their success, and their general encouragement by the educated classes.

As the experiment of a Self-supporting Dispensary has proved so successful at Coventry, as much so in other places, and more so at Northampton, where some £700 was divided last year among the Medical officers, and as the principle of these establishments has so long been recognised and acted upon in the Medical relief clubs scattered all over the country, it becomes a subject of wonder and disappointment that some similar plan has not been carried out in the Metropolis. Here, perhaps, as in too many other instances, the members of the Medical Profession have only themselves to blame. At the present moment the abuse of Medical charity is so great in London that it becomes a matter of the utmost difficulty to establish correct ideas as to the mode in which Medical relief ought to be administered with justice to the giver and to the recipient. Hospitals of every kind, general and special, open their portals to the victims of disease; while the out-patient departments of these establishments distribute advice and medicines in such a wholesale and indiscriminate manner as must tend to render the boon valueless in the eyes of the patients, while some of the General Practitioners in the vicinity are very materially injured. Many of these charities do not require any letter of recommendation from the governors, and administer assistance to all who demand it; although the multitudes who are reported to throng the doors of these buildings cannot possibly receive adequate attendance, even if the Physicians and the Surgeons were to attend upon them the whole of the day, or even if the present staff of officers were doubled. The Medical Profession, instead of denouncing these manifest abuses, actually encourages them; and whatever may be the toil and labour incurred in the discharge of the duties, enough Medical men and to spare are always found ready to compete for the unpaid and thankless posts, and even in many cases to expend their own private means in securing their elections for the offices. In no other Profession do science and humanity, or even more interested motives, lead to such suicidal policy.

The Dispensary system has tended largely to degrade the Medical Profession under the guise of administering relief to the sick. The patients who attend at these institutions may be divided into three classes: 1st. Those who are absolutely poor and destitute, and who are the proper objects for parochial Medical relief. 2nd. The servants of the governors, who thus procure advice and medicines for their dependants at a cheap rate; and, 3rd. The higher classes of artisans and labourers, and the lower classes of tradesmen and shopkeepers, who do not scruple to receive gratuitous relief, but who are

certainly able to pay a small sum in return for the benefits which they receive. Perhaps there may be a fourth class, consisting of the better order of people, who are mean enough to accept the gratuitous services of the Profession; but we hope that such instances of meanness are not so common as many suppose.

Now, with regard to the first class, or the actual paupers, it is clearly the duty of the State, or of the parishes, to provide them with Medical as well as other relief; and if the present staff of Poor-law Medical officers is inadequate in number, or badly paid (as indeed they are), additions should be made both to their number and to their emoluments. It is certainly no part of the duty of a Dispensary Physician or Surgeon to perform the functions of a Poor-law Medical officer. Still we would not altogether exclude this class from the benefits which they may derive from the Dispensaries, or compel every one to accept parish relief; but the case must be rare indeed in which any one above accepting parish relief could not become a member of a Self-supporting Dispensary.

The next class, or the servants of the governors, present many difficulties in their management; because, among the temptations held out to catch the contributions of the charitable, the boon of having their domestics attended during sickness occupies a prominent place in the advertisements. But surely this is indulging in charity at a cheap rate, if, by the moderate expenditure of a guinea per annum, a gentleman or lady can command the services of physicians and surgeons for his household, or for his neighbour's household, the Medical men so employed working for nothing.

The third class, consisting of the higher orders of artisans and labourers and the lower classes of tradesmen and shopkeepers, are the very persons for whom the Free Dispensaries are intended, but who at the same time ought to contribute something to the maintenance of those charities. These persons are quite sagacious enough to know that the labour of the head is as worthy of remuneration as the labour of the hand; and were it not for the indiscriminate manner in which Medical charity is lavished forth, and the general misapprehension existing upon the subject, there is no doubt that this section of the community would willingly contribute something towards the support of institutions from which they derive such solid advantages. It is surely only necessary to point out to such persons the justice and the honesty of rewarding Medical services to secure their frank and zealous co-operation.

In order to strike at the root of the existing evils it is necessary, in the first place, to convince the Governors of Hospitals and Dispensaries as to the propriety of reforming the present system. It is also necessary to impress upon the Profession the duty of defending their own interests. Our great Hospitals are justly the pride and boast of the British nation. Long may they fulfil the designs of their beneficent founders; but we do object most strongly to the indiscriminate Medical relief afforded to hosts of patients, both in the Hospitals and Dispensaries, to the utter destruction of the feeling of independence among the patients themselves, and to the great detriment of the interests of the Profession.

It is perfectly absurd to suppose that the establishment of Self-supporting Dispensaries would injure the General Practitioners; on the contrary, it is the present system of which the Profession has most to complain; a system which accepts Medical services, and gives nothing at all in return. A well-regulated Self-supporting Dispensary would, of course, exclude from participation in its benefits all those who are able to pay ordinary Medical charges, and the power given to the patients of choosing their own Medical attendant would obviate any objection which might be made as to thrusting upon them a practitioner whom they might not approve. In any given district all the Medical practitioners might join in a Dispensary if they chose to do so, and those patients who required

the services of any one in particular might be able to obtain them. Thus all favouritism would be avoided, the patients would be duly attended, and the Medical Practitioner would be fairly remunerated.

### THE WEEK.

THE meeting on Wednesday, of which a short report will be found in another column, to discuss the principle of Self-supporting Dispensaries, is a step in the right direction. The principle is one which certainly deserves discussion, and we trust that the Profession in the various postal districts of the metropolis, and in our principal large towns, will meet together, and give the scheme so long advocated by Mr. Smith a full and fair consideration. We have already expressed some of our own views on this subject, and we feel convinced that the more it is discussed the more it will become apparent that the time is come to reform the existing system of charitable medical relief, to make an effort to raise the tone of feeling and encourage provident habits among the poor, and to secure a fair remuneration for medical services.

It may be well to point out just now a few of the more prominent disadvantages of the Naval Medical Service, for the information of those gentlemen who contemplate entering it, and to contrast it with the Military Medical Service:—

#### ASSISTANT-SURGEON, R.N.

Pay—8s. 1d. per diem.  
No servant allowed.  
Full-pay service intermittent.  
Has a cabin only when the internal arrangements on board admit of it.

#### ARMY ASSISTANT-SURGEON.

Pay—10s. per diem.  
Servant allowed.  
Full-pay service continuous.  
Has a room allowed him.

One of the greatest grievances of the Naval Medical Officer is the intermitting character of his full-pay service, for whenever he is paid off (say every three years) he is placed on the half-pay list, and the interval between that and his re-employment, averaging from six to eighteen months, is lost to him, as it does not count as time served. After twenty-five years' full-pay service he can claim his retirement, but a very small per-centage only are enabled to complete this term, while it is a daily occurrence to meet Surgeons of from fifty to sixty years of age, serving in ships, who have scarce completed twenty years' service. There is no increase of pay between the tenth and twentieth year of service, so that the Surgeon of nineteen years' standing receives but the same remuneration as he did nine years previously. The East India Company is incomparably the most attractive of the public services, as, independently of superior pay, lucrative civil appointments are within the reach of Medical Officers who qualify themselves for them. Now that the Army and East India Company's services are open to public competition, it cannot be expected that Medical men will be so blind to their own interests as to enter the Navy until their present and future position is raised to an equality with that of the sister service. We must refer also to another act of injustice. By reference to the *Admiralty Gazette* of 26th February, it will be seen that twenty-nine naval officers of different grades have received promotion for the recent operations before Canton, but not a single Assistant-Surgeon has been advanced to the rank of Surgeon. Such unjust treatment should, I think, be brought before those students who are thinking of entering the Naval Medical Service. That one at least of our Medical brethren participated in the operations above alluded to, may be seen from the subjoined paragraph of Admiral Seymour's despatches, but even he as yet has received no reward:—

"Soon after seven o'clock Captain Bate, of the 'Actæon,'

and Captain Mann, R.E., were directed to reconnoitre the wall, and select a fitting place for planting our scaling-ladders. In the performance of this important duty Captain Bate was wounded in the chest by a gingall ball from the parapet. Dr. C. A. Anderson, Staff-Surgeon of the 'Calcutta,' at once proceeded, at great personal risk, under a heavy fire, to his assistance, but it was of no avail, as this gallant and highly-esteemed officer died within a few minutes of receiving his wound."

Mr. Gamgee and Mr. West are now doing duty on terms of equality as surgeons to the Queen's Hospital, Birmingham—yet a document is being circulated under the auspices of the Canon Miller, whose peculiar views of the duties of a Christian Pastor we have already commented on, the object of which is to damage the Institution on charges of mismanagement. Mr. Sands Cox has given the most conclusive refutation of these charges, and has shown that the Canon's threat of withdrawing the offertory contributions of his congregation is as unjust as it is uncharitable. Surely the people of Birmingham are not so mad as to allow their noble Institution to be destroyed because an arrogant churchman has found that he cannot do exactly as he pleases with their money or dictate to the governors of the Charity.

The *Northern Daily Express* contains the following advertisement immediately beneath that of Dr. Pearse, which we noticed a fortnight ago.

"MR. WILLIAM PRESTON,  
LATE HOUSE SURGEON TO GUY'S HOSPITAL,  
LONDON,  
4, ELSWICK WEST TERRACE, SCOTSWOOD ROAD,  
NEWCASTLE.

Fee—Consultation or Visit, One Shilling and Sixpence.  
Families Professionally attended at One Guinea per annum.  
All Medicines Supplied Free of Charge."

Such things as these are daily proving how necessary it is to give our Universities or Corporations—or the ruling bodies, whatever they may be, when the Medical Reform question is settled—full power to expel such members as do anything to lower their Profession in public estimation. What would be thought of a lawyer who acted as Dr. Pearse and Mr. Preston have done?

At a time when we are about to seek at the hands of the Legislature means for the abatement of illegal practice, it may not be amiss to observe how insufficiently they have hitherto operated in France, a country sometimes referred to as a model to imitate in these matters, and yet where repressive laws of considerable severity are found inefficient. Besides numerous instances that appear in the journals of complaints of individual practitioners, we may refer to the following petition, addressed by the conjoined Medical Societies of Paris to the Emperor:—

"Sire,—At an epoch in which the history of your beneficence is inscribed in ineffaceable characters on the soil of France, and when society, stimulated by your example, is endeavouring to ameliorate the position of the necessitous classes, the medical body regards it as a duty to direct your Majesty's attention to one of the social wounds which paralyze your generous intentions. Side by side with that medicine consecrated by the experience of ages, and which consoles and cures, a blind and sordid illegal medicine boldly stalks. If in the towns the information of the masses sometimes counterpoises its mischievous effects, this is not the case in the rural districts, where unfortunately ignorance still predominates, and where nevertheless an unlimited publicity is given to the most lying and scandalous promises. Here, sire, is a serious peril, and a barrier which unceasingly impedes the large impulse you give to morality and humanity. Allow us to hope that your Majesty, so solicitous for the infancy of the poor and so provident for their old age, will deign to prosecute your good work by protecting, by means of effectual repression, entire society against the illegal practice

of medicine. Such, Sire, is the prayer of the medical body, so often honoured with the carrying out the benefits conceived by your touching solicitude for suffering, but too often prevented by prejudice from accomplishing its humane mission."

His Majesty received the deputation with great cordiality, and promised to take the object of the petition into consideration. It is well worthy the attention of our own Legislature.

They manage some things well in France. The special correspondent of the *Morning Advertiser* says:—

The Court of Cassation has at last definitively decided that Homœopathists are quacks, and the sale of their harmless globules illegal. This decision has thrown the apostles of that hallucination into dismay. You may remember that in the course of last year the apothecaries of Angoulême (as stated at the time) caused Dr. Moreau, who practises the Homœopathic system of medicine in that city, to be prosecuted before the Tribunal of Correctional Police for having himself provided for his patients the globules which he prescribed, thereby violating the law of the 21 Germinal, An. XI., which accords to regularly licensed apothecaries the exclusive right of preparing and selling medicines. But the tribunal rejected the case. The apothecaries appealed to the Imperial Court of Bordeaux against that decision; but the Court confirmed it, on the ground that the Homœopathic system of medicine being entirely new, and employing infinitesimally small medicines which do not figure in ordinary pharmacopœias, does not fall within the operation of the law in question; and that, consequently, homœopathists can prepare and sell their own medicines. The Court of Cassation being appealed to, quashed this decision as bad in law, and sent the cause before the Court of Poitiers. That tribunal, however, for the reasons stated by the Court of Bordeaux, and for others of a more technical nature, gave judgment against the apothecaries. Under these circumstances a new appeal was presented to the Court of Cassation, and it was yesterday argued at great length. The Court once again decided that Homœopathists cannot make up and sell medicines, and quashed the judgment of the Court of Poitiers."

This opens up a new view of the Homœopathic delusion. No sane man doubts the quackery of the globulists. The question of legality is another matter.

## THE LATE BENJAMIN TRAVERS, F.R.S.

From time to time we have had to announce the decease of the friends and contemporaries of Sir Astley Cooper, that great surgeon whose name will ever be a beacon to successive generations of our Profession. It is now our painful duty to pen an obituary of his first pupil, a gentleman whose connexion with Sir Astley during many years was that of intimate friendship, and whose name will descend with his as co-writer of one of his most practical works.

Benjamin Travers, the second of ten children, was born in April, 1783. He was the son of a wealthy sugar baker in Queen-street, Cheapside, whose descendants in the second generation now form the well-known firm in St. Swin's-lane. After receiving a classical education at the grammar school of the Rev. E. Cogan, at Cheshunt, he became a private pupil of Mr. Friend, formerly of Cambridge, and evidently availed himself of the opportunities thus afforded him for acquiring a sound knowledge of ancient literature. At the age of sixteen he was placed in his father's counting-house, but his father being at that time a frequent attendant on the lectures of Mr. Cline and Mr. Astley Cooper, to which he was accompanied by his son, was induced to yield to the persuasions of the youth, and to permit him to enter the medical profession. Just at this juncture, Astley Cooper was elected surgeon to Guy's Hospital, and young Travers became his first articulated pupil in 1800—not 1809, as stated in the daily papers. Mr. Travers used to relate his *début* in that capacity with much humour: "In the summer of 1800 I accompanied Mr. Cooper in his gig to Newington-green, on the evening of the second day of my residence with him. It was to examine the body of an elderly lady who had died of cancer of the

stomach. The operation was concluded by candle-light, and though I had never before seen a corpse, I was chief assistant on this occasion. I made a strong effort to appear *à fait*, and give all the aid in my power, undressing, and in part sewing up the body, and bringing away a precious, though not over fragrant relic of the old lady's interior on my person. The second part of this adventure was a narrow escape from foot-pads in driving home through a bye-lane. The night being pitch dark, and the neighbourhood not being over built, a low significant whistle from behind the hedge, and the glimpse of a man in a white coat, caused my master to turn his horse abruptly, and gallop back to the first public-house. There the landlord confirmed our belief that we had escaped a notorious gang then infesting those parts; and arming himself with a blunderbuss, accompanied by two pot-valiant customers with other destructive weapons, he marched in front of our horse till we reached the high road. Mr. Cooper's pocket would have afforded booty, no doubt; the valued spoils in my possession would have been less appreciated."

A private dissecting-room at Guy's Hospital furnished the dressers of that establishment with a quiet apartment, and here during the last year of his apprenticeship Mr. Travers gave demonstrations to his fellow-pupils, among whom he also established a Clinical Society. During his apprenticeship he had the advantage of being an inmate of Mr. Cooper's family, and the valuable privilege of his special instruction and example. He says, "I often dined and spent the evening alone with him, and we used to discuss points of physiology together; he would suggest experiments, or direct my attention to cases in the Hospital, with the intention of animating my zeal and industry." With what excellent effect is well known!

Mr. Travers became a member of the College of Surgeons in 1806, and then proceeded to Edinburgh, where he passed a session actively employed in repeating the experiments of Bichat upon the effects of unarterialized blood on the heart and nervous system, and enjoying the society of Dr. Barclay, Dr. Hamilton, Dr. John Thomson, Dugald Stewart, and Professors Playfair and Leslie.

He then made a pedestrian tour to the Scotch and English lakes, and, returning to London, married the daughter of William Morgan, Esq., a gentleman said, but erroneously, to be the founder of the Equitable Assurance Company. This company was really projected by the uncle of Mr. Morgan, Dr. Richard Price.

Mr. Travers now fairly settled down to work, and was immediately appointed Demonstrator of Anatomy at Guy's, which office he filled for many years; and soon after had the additional good fortune to be appointed Surgeon to the East India Company's Volunteer Brigade, after a sharp contest, which he only gained by a single vote. When we consider that he was opposed by Mr. Ramsden of St. Bartholomew's, and Mr. Lucas of Guy's, this success was a feather in his cap. In 1809 his son, Mr. B. Travers, was born.

In 1810, Mr. Saunders, founder of the Eye Infirmary, now the Royal London Ophthalmic Hospital, died, and Mr. Henry Cline was applied to, to fill the office of Surgeon to that institution. He declined, and the proposition being made to Mr. Travers, was accepted by him. For four years Mr. Travers held the appointment singly, and was the first to stand boldly forward as the champion for ophthalmic science, which at that time was at a low ebb. In the preface to his "Synopsis," Mr. Travers says: "In this country, I believe no one before myself, who designed to practise general surgery, ventured to give more than a cursory attention to the diseases of the eye. A fear of being disqualified in public opinion by a reputation acquired in these for the treatment of other diseases, was a motive, however groundless, sufficient to deter surgeons from the cultivation of a large and legitimate field of observation and practice. It was with a public avowal of the sentiments so well expressed by the writers just quoted (Mr. Samuel Cooper and M. Louis), that I accepted the situation of Surgeon to the Eye Infirmary in the year 1810; and from these I have never swerved. At the commencement of the following year the students of Surgery were first invited to attend the practice of the Infirmary, an opportunity eagerly embraced, and which many hundreds have since enjoyed." In 1817 the appointment in question was resigned by Mr. Travers, who in the previous year had taken possession of the residence of Mr. Astley Cooper, in Broad-street, on the removal of the latter to Spring-Gardens, and the opportune retirement of Mr.

Thomas Blizard threw much practice into his hands. He commenced practice in New-court, St. Swithin's-lane. He then removed to 30, New Broad-street, and, as we have just stated, took Sir Astley Cooper's house, 3, New Broad-street, in 1816. In 1811 Mr. Travers communicated to the Royal Society a paper, which was accepted by them, but withdrawn by the author for publication in the volume of "Surgical Essays." In 1813 he was elected a Fellow of that Society. On the death of Mr. Birch, in March 1815, Mr. Travers was elected without opposition Surgeon to St. Thomas's Hospital.

The "Surgical Essays," published in conjunction with Sir Astley Cooper, tended to enlarge the fame of Mr. Travers. The proposition that he should participate in the undertaking originated with Sir Astley, not only from motives of friendship, but from the high opinion he entertained of his old pupil's literary acquirements. It is known that on several occasions he submitted papers, in the compilation of which he wished to be particularly careful, to Mr. Travers's revision. The first part of the "Surgical Essays" was published in 1818, and the demand became so considerable that the book went rapidly through three editions in this country, was republished in America, and translated into the French and German languages. Three articles were contributed by Mr. Travers, one being that "On Wounds and Ligatures of the Veins," which had been withdrawn from the Royal Society; the others were "On Iritis," and "On Phymosis and Paraphymosis."

A second volume appeared in 1819, but circumstances prevented the appearance of the article prepared by Mr. Travers for that portion of the work.

The reputation already acquired by the subject of this notice for ophthalmic skill was greatly enhanced by the publication in 1820 of his "Synopsis of the Diseases of the Eye." This volume is elegantly written, and the illustrations are of a superior order, far better indeed than those which have appeared in many more recent works.

In 1824 Mr. Travers published "An Inquiry into that Disturbed State of the Vital Functions usually denominated Constitutional Irritation," following it in 1834 by "A Further Inquiry respecting Constitutional Irritation and the Pathology of the Nervous System." It is by these works, perhaps, that his reputation as a philosophic writer of a high order was most firmly established. The intention and spirit of the work was to arouse the minds of the Profession to a scientific study of the laws which regulate the vital functions in health, and their derangement in disease; and on this foundation to build a rational system of Surgical pathology. It is but justice to Mr. Travers's memory to state, that when the first of these volumes appeared it was received both at home and abroad as the most important contribution to the science of Surgery which had appeared since the death of John Hunter.

These volumes possess, in an eminent degree, the features which characterized the writings of Mr. Travers; a happy combination of philosophic reasoning, lucid argument, and extensive research mark every page; while the language in which his ideas are clothed is elegant and classical. A happy illustration of this command of language was afforded by the Hunterian Oration delivered by him in 1838, which ranks among the very best ever delivered within the walls of the Hunterian theatre. It was listened to with profound attention by a crowded audience, many of whom retain a vivid recollection of the intellectual treat that day enjoyed.

Mr. Travers from time to time addressed the Societies of which he was a member, and ever spoke with a ready command of words and a precision of style, relieved by a tinge of humour which always told happily. The following is a specimen of the neatness of his composition:—

"Nations, like individuals, are distinguished by a peculiar character of mind, to whatever causes attributable, evinced in their respective modes of observing, reflecting, and acting; and the sentiment of Phædrus is as strictly applicable to the one as to the other:—

*"Sua cuique quum sit animi cognitatio  
Colorque prius."*

I should be sorry to see the sober sense of my countrymen perverted by a taste for fastidious distinctions. Simplicity is the characteristic feature of English Surgery, which is neither more nor less than the application of the principles of inflammation as illustrated by the genius of John Hunter." (a)

(a) Preface to Synopsis.

By no one were the characteristics mentioned, better displayed than by him who penned that sentence!

Mr. Travers was twice President of the Royal College of Surgeons, namely, in 1847 and in 1856-57. He had been a member of the Council since 1833.

Mr. Travers had been fifty years a Fellow of the Royal Medical and Chirurgical Society, having been elected in 1808. In 1827 he filled the office of President of the Society, with distinguished credit to himself. He was a liberal contributor to the Transactions of the Society, as will be seen by the following list of papers:

Case of Aneurism by Anastomosis in the Orbit cured by Ligature of the common Carotid Artery, Vol. ii.

Observations on the Cataract, Vol. iv.

Observations upon the Ligature of Arteries, and the causes of Secondary Hæmorrhage, with a Suggestion of a New Method of employing the Ligature in cases of Aneurism, Vol. iv.

Further Observations on the Cataract, Vol. v.

Further Observations on the Ligature of Arteries, Vol. vi.

Observations on the Rupture of the Stomach from Ulceration, Vol. viii.

Two cases of Aneurism, in which the Temporary Ligature was employed, Vol. ix.

Observations on the local diseases termed Malignant, Vol. xvii.

Removal of the Clavicle, with a Tumour situated in that bone, Vol. xxi.

Case of Strangulated Hernia, in which the Bowel was ruptured by the Patient in his efforts to reduce it, Vol. xxii.

It should be remembered that Mr. Travers mainly helped to set at rest the still "moot" points in his early days concerning the final operation of the ligature upon the trunks of large arteries, and the causes of secondary hæmorrhage after such application; and we believe he is entitled to the merit of having been the first to prove by direct experiment, that a single ligature tied tightly round the intestine of a dog, so as perfectly to strangle and obstruct the bowel, is a *recoverable* mode or form of injury. Mr. Abernethy was charmed with Mr. Travers's work on the Intestines, making mention of its author to his class, and elsewhere, in the handsomest terms. It may interest our readers to know that Mr. Travers always laid claim to the merit of originality, both as regards the experiments concerning temporary application of the ligature to arteries, also in the affair of strangulating the intestine, before alluded to.

As an operator, Mr. Travers was safe, rather than showy; and preferred a neat and careful performance of the operation to any clap-trap display of manual dexterity; whatever he did he did well, and the success which attended his operative practice tended materially to raise him early to that high position which he so long and so honourably maintained.

Besides the great professional skill and knowledge which he had acquired, there were combined in Mr. Travers that intuitive sagacity, that delicate consideration for the feelings of others, and that natural grace of thought and expression which are rarely met with, but when found are the finest characteristics of an English gentleman.

During the most active part of his career, Mr. Travers resided in the City, whence he removed to Bruton-street in 1825. A move of this description is generally attended with some loss, and we believe that Mr. Travers was no exception to the rule. His income in the City exceeded £6000 per annum, but was gained at the expense of health; and we have heard Mr. Travers say that, although he lost fully a third of his income by his removal westward, yet the loss was more than made up in health. He believed that his life was prolonged many years by the removal.

As he advanced in years his practice naturally diminished, and for some time past he resided in Green-street, Park-lane, where his opinion as a consultant was much sought. For many years he had lost the sight of one eye, and had for some time before his death abandoned operating, for which he had become unfitted by the infirmities of age. It is only a few months since the honourable distinction of Serjeant-Surgeon to the Queen was conferred upon him on the death of Mr. Keate.

We ought not to omit to notice that which was at the time thought to be a dishonour done to the Profession at large which Mr. Travers so much adorned in his own person, and towards which he ever evinced a steady loyalty and unswerving

rectitude of purpose; penetrated and humbled as he was by an abiding sense of its grave responsibilities and value to mankind at large. We allude to the fact that when he retired from St. Thomas's Hospital (now some eighteen years ago), where he served faithfully and with the utmost distinction, both in and out of the Profession, for twenty-five years, he was not made or declared Consulting Surgeon to the hospital; an omission the less excusable because the office has since been recognised by the appointment of Mr. Travers's junior colleague, Mr. Green. Mr. Travers was thought by some to be a great Tory and very conservative in professional matters. As regards the administration of our endowed hospitals, this was by no means the case. He considered, in common with the bulk of the Profession, that whenever legislative interference should take effect, these institutions ought not to escape a strict scrutiny. To the abuses of the out-patient system, and many other evils, he was feelingly alive, and never sought to conceal his opinion that reform was greatly needed in the management of the large hospitals.

During many years of his life Mr. Travers had suffered from occasional attacks of palpitation of the heart, and though there might not have been direct relation between the two, his death was caused by pericarditis. For the last two months he had been confined to his room by pain in the leg, and other symptoms indicative of disease of the blood-vessels. His Medical attendants, Sir B. Brodie and Dr. Bright, entertained no doubt of the character of his disorder, and anticipated the usual result, though the immediate cause of death was somewhat unexpected. We may add since learning the result of the *post-mortem* examination, that the immediate cause of death was pericarditis, accompanied by dilatation of the auricles, together with a general softening of the muscular structure of the heart. The serous membrane was firmly adherent to the surface of that organ in many places, showing that this change was chronic or of long standing. One of Mr. Travers's earliest and most distressing symptoms was intense pain in the sole of the left foot, extending upwards in the direction of the posterior tibial vessels. After death the arteries half-way up the leg were found filled with a false membrane or lymph layer, and it is stated that in one place the posterior tibial artery was thickened to obliteration, or nearly so. Several gall-stones were found in the gall-bladder. The other great organs did not appear to have undergone any diseased change of importance. Mr. Travers died suddenly, being at the moment in bed, where he had lain for many weeks in a semi-erect posture.

Mr. Travers was tall, large-framed, and well-proportioned, with a highly intelligent and pleasing countenance; his manners were prepossessing, and in consultation with his professional brethren he showed a highbred courtesy which marked the refinement of his mind. He was ever popular, whether in the Profession or out of it, and the announcement of his death will be received with heartfelt regret, both at home and abroad.

## REVIEWS.

*Ergebnisse und Studien aus der medizinischen Klinik zu Bonn.*  
Von Professor NAUMANN. Pp. 408. Leipzig: 1858.

*Experiments and Researches made in the University Hospital at Bonn.* By Professor NAUMANN.

THE bulk of this work contains observations on pneumonia and phthisis, drawn up from a very considerable number of cases treated in the University Hospital at Bonn. There is nothing new nor very peculiar in this part of the work; but it is well written, and shows the diligence of a careful observer. In the treatment of pneumonia Professor Naumann generally rejects phlebotomy, because, according to his experience, very little relief can be afforded thereby, and the mass of fibrin in the blood is always considerably increased. He concedes, however, that in some cases bloodletting may save life, especially in plethoric persons, where there is disposition to apoplexy, and in cases of pneumonia which have come on after a sudden suppression of the catamenia. As to the internal treatment of the complaint, Professor Naumann is a strong advocate of the tartarised antimony, which is given by him sometimes with the nitrate of potash, sometimes with calomel; but he has observed that its employment is of

little or no use when it is soon followed by diarrhoea. In the treatment of phthisis the author highly praises the beneficial effects of iron, particularly of the sulphate of iron.

We think our readers will be somewhat puzzled by Professor Naumann's thoughts on the physiology of the nervous system as derived from his clinical observations. It is certainly gratifying to see physicians taking up the course of drawing conclusions respecting physiology from the morbid states of the system; but we doubt if Professor Naumann's very peculiar views, into which want of space does not allow us to enter, will be generally received by the Profession.

*The Cause of the Coagulation of the Blood; being the Astley Cooper Prize Essay for 1856, with additional Observations and Experiments.* By B. W. RICHARDSON, M.D. 8vo, pp. 466. London: 1856.

SINCE HARVEY'S great discovery of the circulation of the blood, there is scarcely a physiological problem which has led to so much inquiry as the cause of the coagulation of the blood. Various theories and hypotheses have been advanced as the supposed causes of the coagulation, such as temperature, exposure to air, rest and motion, vital force, chemical hypotheses, electricity, physical interchanges of constituents, and others equally unsatisfactory. The vital, the physical, and the chemical theories were alike defective when the Astley Cooper prize of 300 guineas was offered to the competition of Medical men of all countries; and it is known that among the competitors there was at least one highly distinguished foreigner. The prize was awarded to Dr. Richardson in 1856, and in the work before us he has published the prize essay precisely as it was sent in for competition, with a number of additional experiments and observations, marked off by brackets to distinguish them from the original, and an Appendix, showing the bearings of the subject on practical medicine and pathology.

We are not about to attempt anything like a critical analysis of a work so unusually full, in this book-making age, of the records of original experiments, and the evidences of keen intelligence and profound thought. We shall merely give a faint outline, a mere popular sketch, of what we may justly call Dr. Richardson's great discovery, feeling certain that all who desire to keep themselves up to the professional science of the day will study the work for themselves.

Dr. Richardson then has shown, by experiments which we feel to be conclusive, that ammonia exists in blood as the true blood alkali, and that it is a constituent of the secretions—breath, perspiration, urine, etc. He has proved that the fluidity of the blood during life is due to the presence of ammonia—ammonia being the solvent of the fibrin, and possessing the power, when mixed with the newly drawn blood in certain definite proportions, of retaining the blood fluid so long as it is subjected to the same conditions as in the living body. He has further proved, by a number of simple but ingenious experiments, how the rapidity of coagulation varies with the rate at which ammonia is evolved.

The line of research followed by Dr. Richardson was exceedingly simple, and one purely of induction. Having ascertained that the vapour passing off from the blood contained some principle which had the power of holding blood fluid, each constituent of the blood was examined one by one. Chloride of ammonium is one of these constituents. The effects of this salt on blood were first examined, then its elementary parts, and upon newly drawn blood being subjected to the influence of the base of this salt, the results just enumerated were made out. But this alkaline base is volatile, therefore it was possible that it passed off in blood vapour. The next step was naturally to look for it in the blood vapour, and so looked for it was found. As it existed in the blood, the inference was fair that it existed in the breath and other secretions. Here again it was looked for and found, not as an abnormal product, for as such it had been detected before, but as a normal constituent of the body, and an all-important agent in the acts of vitality.

How much we may learn from one new fact! We now see the last link in the chain of connexion between the animal and vegetable kingdom. Plants require as steady a supply of ammonia as they do of carbonic acid. We know how they take up the carbonic acid we excrete, and restore us the oxygen we require. But how is the balance of nitrogen kept up in the atmosphere for the supply of plants? Dr. Richardson

tells us. By the emanations from animal bodies. We can now see how three or four hundred tons of bicarbonate of ammonia evolved every year by the inhabitants of this metropolis are converted by that wonderful process of vital chemistry into the nitrogenized compounds of our vegetable food. We can see how the putrid emanations from the dung-heap and the cesspool are rendered innocuous in the neighbourhood of luxuriant vegetation. And we can see what an important part ammonia plays in disease. Dr. Richardson has detected it already in abnormal quantity in the breaths of patients suffering from various diseases of a low or adynamic type—purpura, typhoid fever, infantile cholera, and phthisis in its last stages. He shows how the fluid state of the blood in low fevers may be precisely imitated by adding large quantities of ammonia to newly-drawn blood. And this is no small matter. We see how it bears on the cause and prevention of fever. In close, unventilated, filthy places, where ammonia is generated in large quantities and finds no free escape, it, in combination with carbonic acid, diffuses itself freely through the atmosphere. If it is not at once made use of by the vegetable world, or freely dispersed by currents of air, it is re-inspired by the inhabitants of those districts, and may bring their blood into the condition observed in those affected by the low fevers so peculiarly prevalent in such places. It would seem that even one person may so adulterate the air of a room that no indication can be obtained of the presence of ozone, although it may be detected immediately outside the window of the room. We need not say how active an agent ammonia is in preventing the indications of the ozonometer, nor point out the extremely important practical results of such researches, or of the more recent which Dr. Richardson has now given us in his Appendix. Suffice it to say, that the Appendix contains most interesting and suggestive chapters on the super-alkaline conditions of the blood in relation to disease, on ammonia as an exhalation from the body, on the effect of lactic acid on animal bodies, on the deposition of fibrin in the heart and blood-vessels during life, on the alkalies and acids as remedial agents, on the application of ammonia to the operation of transfusion of blood, and on some conditions of the blood after death in relation to medico-legal inquiries. The demonstration of the truth of the long suspected relation between lactic acid, rheumatism, and endocarditis, would alone serve to place the author high in the rank of scientific physicians.

It is with extreme pride and satisfaction that we congratulate our countryman upon the appearance of his great work; and looking to the early age at which it has been produced, we very confidently express the hope that it will prove to be the forerunner of a long career of honour and success.

*Researches on Epilepsy: its Artificial Production in Animals, and its Etiology, Nature, and Treatment in Man.* By E. BROWN-SÉQUARD, M.D. Republished from the *Boston Medical and Surgical Journal*, Nov. 1856 to Nov. 1857. Pp. 82. Boston: 1857.

THE thin volume of which the above is the title, affords much matter for study and reflection, while its contents are well suited for controversial discussion more extensive than we are able to devote to it. There is scarcely a page in the book to which we could unhesitatingly subscribe, while there is scarcely a page which has not proof of the shrewdness of the author as an observer, or of his critical acumen as a student of the history of his subject. Our readers can scarcely fail to have heard of the experiments which form the basis of Dr. Brown-Séquard's views on the nature of epilepsy; experiments made for the purpose of determining the physiological properties of the spinal cord. From them he concludes that section of certain portions of this organ induces convulsions not only resembling, but identical with epilepsy. The injuries which Dr. Séquard has found to cause epilepsy in rabbits are:—1. A complete transversal section of a lateral half of the organ. 2. A transversal section of its two posterior columns, of its posterior cornua of grey matter, and of a part of the lateral columns. 3. A transversal section of either of the posterior columns, or the lateral or the anterior alone. 4. A complete transversal section of the whole organ. 5. A simple puncture. This list comprises a great variety of injuries that may be inflicted upon the cord, and the very fact that they are all followed by similar symptoms seems to us to

impair very much the value of the inference that these symptoms are identical with epilepsy. The author himself has clearly had misgivings on the subject, for he has ransacked other authors to find cases bearing an interpretation analogous to his experiments, and he is, necessarily, not very successful in his search. Necessarily, because however great the analogy between the symptoms resulting from the lesions of the cord in guinea-pigs to the symptoms of human epilepsy, anybody who has carefully watched the sequence of symptoms in man must arrive at the conclusion that the brain is the organ primarily involved. The eccentric aura is a rare symptom; the insensibility, the vertigo, the cephalalgia, and other cerebral affections, pre-eminently belong to epilepsy; while there is ample evidence to show that even the aura affecting the extremities may be referable to an affection of the brain itself. The author's scepticism regarding his own inferences becomes manifest as we proceed in the book. For after discussing the various theories held in regard to the *causa proxima* of epilepsy, we find it stated, that "it is very probable that the seat of epilepsy is in the upper part of the spinal cord, in the medulla oblongata, and the pons varolii, where the roots of the trigeminal and of the first spinal nerves have their origin." Again, after perusing some very interesting observations on the cause of the pallor that generally prevails in the first stage of an epileptic paroxysm, and of the flushed appearance that succeeds, we come to a passage conveying that the contraction of the cerebral vessels causes loss of consciousness, while the stimulus of the venous blood to the base of the brain and the spinal cord causes convulsions. Here, then, it is distinctly enunciated, that the first disorder takes place in the cerebrum; but though we willingly subscribe to this doctrine, we cannot but think that it tallies little with the views of the author regarding the relation of the spinal cord to epilepsy, as given above.

If we sum up our impression of the book, we should say that the distinguished author has been too anxious to reconcile certain results that he has obtained in vivisections with the records of disease given by practical, or rather practising physicians. We do not know what his own experience of the disease may be, but we cannot but conclude, both from his constant reference to the cases of disease detailed by other neurologists, and from the very brief allusions to the methods of treatment which he himself suggests, that his clinical acquaintance with epilepsy is extremely limited. Still the book is one that deserves to be studied; it contains many valuable and suggestive remarks, and, as a record of Dr. Brown-Séquard's experiments and conclusions on a most important topic, should find a place in every medical library.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON EMBOLI.

By Professor SCHUTZENBERGER.

THE following are the principal conclusions of an elaborate series of papers, published by Professor Schutzenberger of Strasburg upon the obstruction of arteries by fibrinous clots detached from the heart or large vessels.

1. Fibrinous concretions or solid bodies formed in the heart or large arteries may become detached from their primary seat, be carried into the torrent of the circulation and obstruct different secondary branches of the arterial tree. The circumstance is neither absolutely rare or exceptional, and it constitutes a special and very remarkable affection of arteries to which Virchow has given the name of arterial emboli. 2. The existence of the affection is proved, (a.) By scientific induction, which demonstrates the possibility of the formation of solid bodies in the heart and large vessels, and the probability that such bodies may become free and floating; and by experiment, which proves that the sanguineous current may carry them to a distance. (b.) By numerous and conclusive clinical and microscopical observations, agreeing among themselves and admitting of no other interpretation. (c.) By microscopic researches, which have shown in some cases the speciality and identity of certain of these bodies simultane-

ously observed in the heart and in the plugs obstructing the arteries. 3. Arterial emboli is then a real and very serious disease, not of infrequent occurrence, but long misunderstood. It should be admitted into the nosological scheme, and deserves all the attention of the clinical observer and the pathological anatomist. 4. It has been observed as a consequence of (1.) Gangrenous phlebitis of the pulmonary veins. (2.) Of organic affections of the left side of the heart; and of (3.) The atheromatous degeneration of the large arterial trunks. Its most frequently observed cause is found in the fibrinous, or calcareous concretions, or the polypiform excrescences developed on the mitral valve, and carried away by the circulating torrent. 5. The form, size, consistence, colour, and nature of these obstruating bodies are variable and notably differ, according to whether the obstruction examined be old or recent. In the former case they may have undergone transformations, which may render them unrecognisable; while in the latter, their fibrinous, calcareous, verrucous nature may be shown. 6. When the patient does not succumb to a first arterial obstruction, generally others are produced, the multiplicity and succession of the arterial lesions being one of the characters of the disease. Multiple obturation may be successively produced from the periphery towards the heart, either in various points of the same arterial branch or in different arterial divisions. 7. The arteries which have been most frequently found obstructed are the sylvian, the internal carotid, the arteries of the lower and upper extremities, the splenic and renal arteries, the external carotid, the mesenterics, etc. 8. The obturation is ordinarily produced at the point of narrowing of an arterial branch immediately below the bifurcation, or the point of departure from a large branch, in the points where the artery incurvates or traverses aponeurotic or bony canals. 9. At first the arterial coats are healthy, and the plug is surrounded by a recent coagulum, which extends upwards to the next collateral. Below, the artery may be empty or may contain recent coagula. The plugs differ from secondary coagula by their colour, consistence, and composition. As a consequence of arterial obturation the outer coat may inflame consecutively. The plug contracts adhesions with the inner coats, and the whole is transformed into a ligament-like tissue. 10. If, after the obstruction, a sufficient collateral circulation be set up, the lesion remains localized, and only gives rise to temporary functional disturbance. But if such collateral circulation be not set up, or only imperfectly, consecutive changes are produced in the organs to which the artery is distributed. In the case of obturation of the arteries of the extremities, in the absence of collateral circulation, mortification, or gangrene, general or partial, dry or humid, may be produced. In parenchymatous organs very exactly circumscribed sanguineous or fibrinous infarctus are produced. In the brain this infarctus usually gives rise to yellow ramollissement, and it is highly probable that certain circumscribed indurations are due to obturation of the arterial ramuscles. In the spleen and the kidneys the infarctus constitutes an entirely special lesion, generally of a conical form, exactly limited, of different colour according to its age, and frequently more dense than the remainder of the parenchyma. It is probable that emboli of the small arteries may give rise to other, as yet little known, lesions of the parenchymatous organs. 11. The symptoms vary according to the arteries obstructed. Obturation of the cerebral arteries gives rise to disturbance of function analogous to an attack of apoplexy. The symptoms do not differ from those attendant upon cerebral hemorrhage or acute ramollissement. Emboli of the arteries of the limbs is indicated by feelings of numbness, pricking, painful shootings in the limbs, and cessation of the beating of the arteries. These symptoms may disappear if a collateral circulation becomes established, but when this is not the case the ulterior symptoms are those of gangrene. 12. The treatment of the affection is at present only palliative and symptomatic.—*Gaz. des Hôp.* 1857. No. 80.

#### EXCERPTA MINORA.

**Black Cataract.**—M. Sichel had long laid down that the colour of this cataract is due to its great density, and not to the presence of any pigmentary element. He recently submitted a specimen of this form of cataract to M. Robin for examination, who, after describing the microscopical appearance, says, "The alteration which causes this colour is thus very simple. It is in nowise due to the formation of new

microscopic particles, resembling pigments or anything else; but consists solely in a change in the molecular constitution of the tubes, rendering their transparency notably less, a change consequent upon the disturbance set up in the intimate phenomena of the nutrition of these elements."—*Gaz. Méd.* 1857, No. 61.

**Chlorine Fumigations in Cholera.**—M. Nonat draws attention to the remarkable effects which during the epidemic of 1844 the extrication of chlorine seemed to exert in preventing the propagation of cholera by patients admitted with that disease into his ward in La Pitié. He contrasts this result with what was observed in the same wards in 1849, and in those of his colleagues, in which chlorine was not employed. He employs the chloride of lime, distributing it in several smallish vessels through the ward, in preference to one or two large ones. Some of these vessels should be especially placed near the patients who are emitting the cholera miasmata in abundance. The fumes should not be disengaged in quantity sufficient to be perceived.—*Moniteur des Hôp.* 1857, No. 81.

**Medication of the Uterine Douche.**—M. Devilliers relates a case in exemplification of the modification he has introduced in Kiwisch's mode of employing the uterine douche for the induction of premature labour. In this case the ordinary douche had been employed several times in vain, when the author induced labour pains rapidly by propelling the water with some force between the membranes and the uterine parietes by means of an injection pump, to which a long curved metallic canula was attached.—*Moniteur des Hôp.* 1857, No. 91.

**Injection of Carbonic Acid Gas into the Bladder.**—M. Paul Broca has endeavoured to extend the anæsthetic application of this substance to painful affections of the bladder, introducing and letting it remain in contact with the organ. As a means of palliating pain, and relieving vesical tenesmus, some very remarkable results have been obtained. The bladder is distended with the gas, which becomes so slowly absorbed, that some still remains at the next miction, though this may not take place for three or four hours. The anæsthetic effect produced lasts for many hours.—*Moniteur des Hôp.* 1857, No. 93.

**Purulent Absorption in the Crimea.**—In a recent discussion upon this subject, M. Mounier observed that there is in the atmosphere *quid ignotum*, which, according to the medical constitution, renders operations innocent or dangerous, favouring or preventing purulent resorption. During the campaign in the Crimea he performed "two thousand amputations," in a hospital containing 600 wounded, between 15th Sept. and 20th Jan., without a single case of purulent resorption occurring. After that period this accident became of quite ordinary occurrence, gangrene, scorbutus, and typhoid fever, it is true, raging with violence. The wards were encumbered with soldiers having their mouths bleeding, and their limbs frozen, and passing numerous stools. "My position then was a terrible one."—*Moniteur des Hôp.* 1857, No. 148.

**Malva moschata in Idiopathic Constipation.**—This substance, employed as a laxative by the Greeks and Romans, according to the investigations of M. Duvignac, forms the best substitute for castor-oil, being as mild and as certain in its operation, without possessing its nauseous qualities. He administers it in the form of a *bon-bon*.—*Moniteur des Hôp.* 1857, No. 154.

## GENERAL CORRESPONDENCE.

### TYPHUS AND TYPHOID FEVER.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have never had much relish for questions of priority, and had this been the only point raised in my friend Dr. Murchison's very flattering notice (a) of my paper, (b) I should not have been tempted to break the silence I have maintained for more than seventeen years. But having at length taken pen in hand, I wish, with your kind permission, and craving the indulgence of your readers, to dispose of a variety of details, which, though somewhat of a personal

nature, bear more or less directly on the subject in hand. And now, in order to prevent all misapprehension, let me preface this explanatory statement by frankly avowing that, while I have much cause for dissatisfaction with myself, I have no cause of complaint against any one of the many who, either long ago or very recently, either parenthetically or at great length, have done me the honour of mentioning my name and labours in connexion with this important and deeply interesting subject; nor yet against those who have passed me over in silence. On the contrary, while deeply grateful for the highly eulogistic terms in which some have noticed my humble endeavours to throw light on one of the dark places of pathology, I can but applaud the sense of justice which has prompted others at least to name me, and the caution of others still, who have judiciously avoided any allusion to what they have probably never seen. I am well aware that many, who are reasonably well acquainted with what has been written on the subject, have never seen my paper, and I should be much surprised to learn that even one in ten of my personal friends had ever set eyes on it, much more, that half the number had read it through. Such is the natural fate of most "papers." The late distinguished Dr. Bartlett, at p. 283 of his admirable work on "The History, Diagnosis, and Treatment, of the Fevers of the United States," says, "I cannot help remarking that it is somewhat singular that among the many observers whom he quotes in support of the views which it is the object of his paper to establish and to illustrate, he should have wholly overlooked the researches of our countryman, Dr. Gerhard, who, by his history of the epidemic typhus of Philadelphia in 1836, had done more than any other observer towards determining the very questions which constitute the subject of Dr. Stewart's essay." My apology for this omission is that I did not obtain access to Dr. Gerhard's very able papers till long after the publication of my own. Had they been published separately, as they so well deserved, it is not probable that I should have been subjected to this great disadvantage. I suppose I may attribute to the same cause the absence of any allusion to my labours in the classic work of Dr. Wood of Philadelphia. In following Dr. Gerhard's example, and inditing a paper instead of a book, I was mainly influenced by the feeling, which I shared with many wiser men, that redundant authorship was one of the sore evils under which Medical science was groaning; so I strove to condense the numerous facts which I possessed, and the inferences to be deduced from them, into the narrowest possible compass. But I have been long convinced that my much-valued friend, Dr. Jenner, has followed a course far more conducive to the interests of science, though to himself more irksome, in sending forth, with ample details and through a variety of channels, his most accurate and instructive observations.

A few words as to the origin of my paper, and my object in writing it. My attention was first specially directed to the study of fever by my friend, Dr. Peebles, who, during his long residence in Rome, had observed the maculæ, now so familiar to us, as a constant concomitant of the contagious fever of Italy, and who, early in 1835, first pointed out to Dr. Perry (then Physician of the Glasgow Fever Hospital), the almost constant presence of the very same maculæ in the typhus of the West of Scotland. I was present on that occasion, and from that day forward the eruption, the very existence of which had been overlooked, was observed and noted in the overwhelming majority of the cases admitted. I was a frequent visitor of the wards of the Fever Hospital during the succeeding year, but it was not till my appointment as Resident Clerk in the summer of 1836 that my systematic study of fever began. For several months after that date, Campsie and its neighbourhood (about nine miles from Glasgow) supplied us with pretty numerous cases of typhoid fever, of which, so far as I know, Glasgow did not furnish so much as one. I mentioned in my paper that "Dr. Perry was the first whom I heard maintain the complete difference of the two eruptions." Whether this was before or after the appearance of Dr. Gerhard's papers, I have no means, at this distant date, of positively affirming. During the frightful epidemic that followed—from September 1836 to Midsummer 1838—when a notable diminution of the cases of typhus took place—thousands of cases passed through the wards of the Fever Hospital. Being frequently summoned, at all hours of the long winter nights, to cases of laryngitis, or of coma coming on with the suddenness of an apoplectic seizure, I had many

(a) Medical Times and Gazette, December 19, 1857, p. 643.

(b) Read in April, and published in the Edinburgh Medical and Surgical Journal for October, 1840. Vol. liv.

opportunities of seeing typhus in its highest development, and of recognising the faithfulness of the descriptions given by Pringle, Hufeland, Reveillé Parise, Hildenbrand, and others. Even of Armstrong's "congestive typhus" I saw not a few examples, and adopted his treatment of free bloodletting with complete success. But no description I have yet seen exceeded in truthfulness, or nearly approached in graphic brevity and power the memorable lazar-house scene in "Paradise Lost." After what I saw during many successive months at Glasgow, no details, however startling, of the Oxford "black assise," of Torgau, of Saragossa, or of the French army in the Crimea, can excite my wonder; though to hear any one say that that disease and typhoid fever are one and the same surprises me more and more. Of the pathological features of typhus, both during life and after death, neither my colleague, Dr. Anderson, nor myself, was unobservant, for, at his suggestion, we undertook a long series of observations, of which I shall only say that the very completeness of the resulting materials, and the enormous labour which a thorough and exhaustive analysis of them would involve, are among the chief reasons why they have not yet been put to the use for which they were originally intended.

It was not, therefore, the lack of materials that kept me from giving a full-length representation of typhus. Having taken my materials with me to Paris with the view of extending my acquaintance with the phenomena of typhoid fever, and comparing them still more carefully with those of typhus, I found an opportunity early in 1840 of turning them to account. A gentleman, who has since achieved a deservedly high literary reputation, read a paper on Fever, which I listened to with deep interest on account of its classic style and the extensive acquaintance it displayed with the literature of the subject. But my bedside observations had led me to conclusions so widely different from the views of Dr. Barlow, and my notes of interrogation and objections taken during the reading of his paper were so very numerous that I might have prolonged my discourse till midnight without exhausting my subject. I accordingly gave notice of a paper on the chief points of difference between typhus and typhoid fever. The first part was read on the first evening of the summer session, before a numerous auditory, presided over by M. Ricord, and the remainder at the next weekly meeting of the Society.

The twofold object I kept constantly before me in drawing it up was to present as clearly and as concisely as possible the leading features of the two diseases. I might have considered *seriatim* all the twenty-five symptoms which I had recorded daily in 145 cases of typhus, and all the complications and sequelæ which any of these cases had presented, besides giving a detailed account of the state of each organ, as ascertained by a most careful and minute examination, in twenty-two fatal cases. After due reflection I decided against this course. My object was diagnosis, which is rather hindered than helped by dwelling at great length on minute features of difference. Conceding the features of resemblance, and briefly but distinctly stating them, I insisted at length on the numerous and remarkable differences which, to my mind, made the idea of identity utterly untenable. So rigidly did I adhere to this rule that I left out, with some regret, the results of an analysis which cost me not a little labour, and to which I referred in the following terms:—"I shall not be tempted, by the highly ingenious and visionary conclusions drawn by Valleix from his six cases of typhus to make any lengthened digression. That author actually considers the absence of headache and affections of the organs of sense as important diagnostic marks of typhus. Instead of wearying the reader with the laboured refutation I had prepared of this strange fancy, I shall merely state," etc., and here follow some details as to the headache and the affections of sight and hearing.

Doubtless I could have established, in opposition to M. Valleix, the greater frequency and gravity of these symptoms, as also of delirium and stupor, in typhus than in typhoid fever; but the difference did not appear to me sufficiently striking to warrant my going into such detail as would have been necessary to make it apparent. But, while my object was to establish a clear diagnosis, I did not feel that I was called upon to begin *de novo* the investigation of typhoid fever, in reference to which, as I stated at the outset, "the standard works of Chomel, Louis, and others, had achieved the triumph of pathological science." While, therefore, I was

bound to give proof of my perfect familiarity with the pathology of typhoid fever, and to show that I had observed it carefully both at home and in Paris, I felt that to go over anew the ground so thoroughly explored by such masters as Louis and Chomel, would be naturally enough reckoned a piece of impertinence in one who had scarcely finished his period of pupillage. I therefore took their data as conclusive evidence on the subject of typhoid fever, adding the results of my own observation, as in almost entire accordance with their deductions; while for my statements on typhus I relied mainly on the facts I had myself collected. By a careful analysis and comparison of these data, I proved:—

1. That while typhoid fever is but slightly contagious in all its stages, typhus is highly so, especially during convalescence.

2. That while the great majority of cases of typhus can be clearly traced to contagion, a very small proportion only of the cases of typhoid fever can be traced to that source.

3. That the course of typhoid fever is lingering, while that of typhus is rapid, the mean duration of the former being fully one-third greater than that of the latter.

4. That this depends partly on the not unfrequent occurrence of true relapses in typhoid fever, as many as three successive attacks, each separated from the other by an imperfect convalescence taking place during one protracted illness, such a phenomenon being absolutely unknown in typhus. This remarkable feature of typhoid fever, which I believe I was the first to point out, and which I have often subsequently verified, seems to me of itself fatal to the idea of its identity with typhus.

5. That the occurrence of marked and sudden crises is as common in typhus as it is rare in typhoid fever.

6. That while in the immense majority of cases of typhoid fever, diarrhœa, circumscribed abdominal pain, and tympanites are coincident, and form an almost pathognomonic group of symptoms; in typhus, on the contrary, "the coincidence of abdominal pain with constipation is to its occurrence along with diarrhœa as three to one," and in many cases free purgation or spontaneous diarrhœa was followed by marked and immediate relief. The comparative infrequency of tympanites, its co-existence with constipation, its rare coincidence with diarrhœa, and the absence of any "proportion between the extent of abdominal tension and the pain experienced," were likewise fully established.

7. I adduced an almost superfluous mass of evidence to prove that the rubeoloid rash of typhus, which is very irregular in form, "very often confluent, and generally level with the skin," comes out in one crop, and "continues throughout the disease; that it, in all cases, presents the two periods, longer or shorter, according to circumstances, of increase and decline; that in the more severe cases it may exhibit, during the period of increase, four different states, being florid, dark, livid, and petechial; that it is quite different from vibices and purpura, which are of rare occurrence; and that the abundance and particularly the darkness of the eruption may be said to be proportional to the severity of the disease." That, on the contrary, the typhoid rash, which "is distinguished from the morbilliform eruption of typhus by being distinct, rounded, slightly elevated, almost papular, and of nearly uniform size," comes out in successive crops (each spot disappearing in three or four days), and "never becomes petechial or even dark, the last crops" (even in moribund cases) "being as florid as the first." Further, it is "beyond a doubt that there is no relation between the eruption and the severity of the cases." I therefore unhesitatingly concluded, in opposition to Chomel, "that the typhus differs from the typhoid eruption in its form, its duration, the changes it undergoes, and the relation it bears, as to colour and quantity, to the severity of the disease."

As regards nomenclature, I venture with diffidence to object on any term introduced by one so conscientiously and scrupulously accurate as my friend Dr. Jenner. I cannot accept "mulberry" as an improvement on "rubeoloid," or "measly," rash. Those who expect to find the typhous eruption in all cases more or less livid, will, I believe, be often disappointed, and consequently embarrassed in their diagnosis. I am much within the mark when I say I have seen *hundreds* of cases of genuine typhus in which the rash never approached the mulberry hue. In 59 of 139 cases which I observed with the greatest care, it remained "pale

or florid throughout." I therefore adhere to the old term "rubeoloid," as on the whole preferable.

8. I proved the absence, in typhus, not only of intestinal ulceration, but of anything like a fixed relation between the number of glands visible after death, and the diarrhoea, tympanites, or abdominal pain present during life. But "as the number of enlarged follicles increased, the cases of spontaneous diarrhoea diminished, and those in whom consecutive diarrhoea and costiveness were observed became more numerous. In fact, not one of those in whom the greatest number of enlarged follicles was observed, but was either constipated or had diarrhoea brought on by medicine during life; showing that the appearances observed in typhus depend upon local irritation, and not on specific disease."

Having established all these points on data which I felt to be incontrovertible, which might be strengthened by additions, but could not be overthrown, it seemed to me that I had left little undone that could be achieved by the examination of symptoms and post-mortem appearances. It would therefore have been strange if, after all this laboured array of proof, I had myself remained a doubter. Such scepticism—call it caution, if you will—would have justified almost any amount of resistance on the part of others to the clearest evidence. And it is this alone which has impelled me to ask a hearing, in the hope of removing the impression which the paragraph quoted by Dr. Murchison, taken by itself, is fitted to convey, viz. that I was not myself fully convinced of the diseases being really two. But if my own mind was made up, why did I even appear to doubt, as when I ask, "Are they, then, identical, or are they not?" and answer, "I feel that it would be presumptuous in me to hazard a direct reply." I did feel that it would be presumptuous in me authoritatively to lay down the law:—

1. Because the dogmatic assertion of an inexperienced youth could add no weight to his facts and reasonings, but was most likely to arouse prejudice, and needlessly to provoke opposition, and,

2. Because I could not help seeing that the evidence was incomplete without careful observations on the causes tending to produce the two diseases, their respective haunts, and the possibility of the phenomena of the one being produced by the contagion of the other. This was the undertaking I proposed to myself on taking up my abode in London. I had had no previous opportunity for such an investigation. Glasgow imported all its cases of typhoid fever from Campsie; and so striking was the contrast they presented, that even the nurses made the diagnosis for themselves, and used to meet me on entering the wards with, "Here's another of these odd cases, Sir." Edinburgh drew its supply from Linlithgow, and from Anstruther in Fife, where typhoid fever was endemic. In Paris typhus was unknown. But in London typhus and typhoid fever exist side by side. So, though past experience in similar inquiries warned me of the irksomeness of the task, I resolved to compare them for myself in the back slums of the great metropolis. Had my appreciation of the drawbacks been somewhat less thorough, the cherished plan might have been carried through; and my regret that I should have allowed any obstacles to baulk my design, only enhances my admiration for those who, like Dr. Jenner, are content, in the service of science,

"To scorn delights, and live laborious days."

He has his reward, and I should feel ashamed to grudge it him.

Still, tho I was thoroughly persuaded of the specific difference of the diseases, is plain from many passages in my paper. Thus, near the beginning, (c) "In speaking of the two varieties of fever as totally different diseases, . . . I have merely employed a phraseology in common use, and have expressed a conviction forced upon me by the consideration of facts and reasonings, which I now proceed to unfold." Again, (d) "It were difficult to find a more striking instance of the little effect of the circumstances we have mentioned (filth, overcrowding, want of ventilation, etc.) in producing typhoid fever, than the epidemic at Bischofsheim, in the department of the Lower Rhine, in August, September, and October, 1832. (e) The disease first showed itself, without suspicion of being transmitted, in the upper, best aired, and, as it is ex-

pressely said, "the most healthy part of the village," which is situated partly on and partly at the foot of a rising ground; and spread successively to the middle and lower quarters." I had also been much struck with the prevalence of typhoid fever in country places in Scotland, and its non-occurrence in the great centres of population, where typhus never dies out, and commented on it as follows:— "If, then, dothineritis is the same disease, and depends on the same causes, as typhus, how does it happen that the former is produced at Linlithgow and at Anstruther, and not in Edinburgh, where the latter is constantly occurring, and where so many circumstances favourable, not only to its production, but (by the hypothesis) likewise to that of dothineritis, are always at work?" (f) These facts, coupled with the occasional presence of a well-marked intermittent type during the stage of invasion, have long seemed to me to point to a malarious origin of typhoid fever. I conclude with one more quotation: (g) "Having thus entered pretty minutely into the pathological anatomy of typhus, I put it to every one who has ever seen the two diseases, or read the descriptions given by the best authors, of the lesions so constantly observed in typhoid fever, whether those found in the former disease can with any truth be called 'perfectly identical' with those of the latter. That the existence of trifling intestinal disease in typhus attests its general family resemblance to typhoid fever, as the presence of organs in a rudimentary state shows the analogy subsisting between individuals of different species in the animal kingdom, might be more readily admitted; but that they are one and the same species, numerous well-established facts seem most clearly to disprove."

I am, &c.

A. P. STEWART.

74, Grosvenor-street, W.

#### PROLAPSUS UTERI.

[To the Editor of the Medical Times and Gazette.]

SIR,—In carefully looking over the interesting papers by Dr. Savage, I, as well as many of my professional friends, have been struck with the impression which it conveys, that I have merely followed in the footsteps of Fricke and Geddings. I feel perfectly assured that Dr. Savage does not intend to convey the idea that such is the case; but, from the mode in which it was necessary for him to class the consecutive operations proposed for prolapsus, in order to complete his admirable summary, and the way in which he has worded it, the deduction might be drawn that I only imitated what others had already done. I think it, therefore, due to myself to again state, that I only heard of Fricke's operation from Mr. Spencer Wells three years ago, and of Geddings's, from Dr. Savage himself, two years ago. Dr. Savage telling me that he had discovered Geddings's monograph in the Library of the Royal College of Surgeons, and which I have not yet seen, I was led originally to perform my operation, by observing that in cases of ruptured perineum (where the tendency to prolapsus of the uterus is very great), after the perineum had been restored, the uterus was retained *in situ*, and all the symptoms of prolapsus disappeared. From this practical observation I drew the deduction, that in certain cases of prolapsus resisting other means of cure, it would be advisable to contract the opening and calibre of the vagina, and thus give an artificial means of support.

I would wish further to observe, that Dr. Savage's illustration of my operation does not give at all a correct view of it as I have practised it for some years past. I remove quite as large a portion of the surface as he does; and the difference between his operation and mine is, that I am content to remove merely the mucous membrane and loose skin of the labia, whilst he removes the vagina itself, which I have not yet had reason to consider necessary.

There are two practical points upon which I lay great stress. 1. The introduction of a catheter into the bladder with a bag attached to it, so as to prevent that viscus ever being filled with the urine, and thereby dragging down the uterus. 2. Not to retain the deep sutures beyond the evening of the second day.

I may mention that, out of all my numerous operations, can only trace three in which it has not been successful.

1. In the first of these the poor woman is in the last stage of phthisis, and all her tissues are absorbed.

(f) P. 336.

(g) Pp. 336, 337.

(c) Edinburgh Medical and Surgical Journal, vol. liv. p. 292.

(d) P. 296.

(e) Gazette Médicale for 1834.

2. The woman went about the trying and laborious work of the wash-tub much too soon, without wearing any bandage or other support.

3. In the case of E. M., I have lately heard from Mr. Buller, of Reading, that the uterus has again pushed its way through the vagina. This is one of the cases in the virgin in which there is complete inversion of the vagina, which no operation of this kind can relieve.

I also know of one case of prolapsus of the bladder, which has returned again after a second confinement.

I am, &c.

J. BAKER BROWN.

17, Connaught-square, Hyde-park, March 1868.

### SPONTANEOUS CURE OF CATARACT.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am induced to send you the particulars of the following case for insertion in the Gazette, from seeing a brief report of a somewhat similar one occurring under the care of Mr. Solomon, of Birmingham:—

"T. H., age 30, of light complexion, and temperate habits, married, an iron-turner. About three years ago, while at work, he received a blow on the right eye-ball from a piece of steel. He suffered intense pain for three days, but without any impairment of vision. He was able to remain at work. The inflammatory symptoms were subdued in three weeks, by which time his sight in the affected eye had become a little dim. In six months more he was quite dark. The left eye remained perfectly sound. He had been under the care of several surgeons, both here and in Manchester. I first saw him two years ago, and found a large soft cataract in the right eye, of a bright white appearance. It entirely filled the pupil, which was much dilated, and was apparently in contact with the iris, although he suffered no pain, in fact the cataract was visible at several yards distance, and disfigured his countenance.

"I told him what Mr. Windsor, of Manchester, and others, had told him before—that he had better allow it to remain so long as his other eye was good, but that if he was determined to have it removed, he must submit to an operation. I lost sight of him till about three months ago, when he called to tell me that a few weeks before he happened to close his sound eye, and found that he could see his fingers indistinctly with his previously blind one. His sight gradually improved until I saw him. On examination, I found the opaque lens had become entirely absorbed (displaced?), both eyes presenting the same appearance, only the right eye is unable to see any small object distinctly without the use of a convex lens. The original wound must have been extremely slight, as there was no trace of wound or ulcer on the cornea. He is a healthy subject, and has been in perfect health ever since the accident.

"In Mr. Solomon's case, the hyd. c. creta may have had some influence in exciting absorption, but in this case to the *vis medicatrix nature* alone must the cure be attributed.

I am, &c.

JOHN LIVY.

St. George's-terrace, Bolton.

### MR. SYME'S CASE OF CANCER OF THE TONGUE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In his letter in your Journal of the 27th ult., the Pathologist of the Edinburgh Infirmary defends (what no one has gainsaid) "the publicity given to the performance of post-mortem examinations" in the Institution. My complaint was directed against the want of publicity given to the Report which he drew up and recorded of Mr. Syme's case, the account of which to this hour is "all a blank" to the Profession, and the record itself "a sealed book," a "mare clausum" to all the students attending the Hospital; such a practice, in my mind, would be "more honoured in the breach than the observance." The regulations to which the Pathologist refers, seem to me to come more appropriately under your editorial province, than to call for comment from me, and I do trust you will inform your northern readers how these stand as compared with the regulations for the publications of reports of cases in the London Hospitals, and whether you consider the paid labours of an official functionary, whose salary is drawn from the revenue of an Hospital which is col-

lected from voluntary public contributions throughout Scotland, as well as from heavy fees exacted from the students for admission, and derived from various other sources, ought in any sense to be regarded as *literary property*? Is it right that the official reports of a Pathologist, so circumstanced as to place and pay, should be entirely subject to the control of one man—

"Dress'd in a little brief authority."

possessing their responsible power, to order or to suppress their publication, according as a sullen fit of humour, or a perverse freak of temper may direct? The hue-and-cry for University Reform rages in this city; but does that Institution not lack amendment, where such a great practical evil exists as is only to be found in a Circumlocution Office, where the progress of truth and knowledge is arrested at the very threshold, until the authorities be satisfied as to the grounds on which the application is made? Such are the terms, it now appears, on which Medical investigation is permitted to be conducted in the Clinical department here! What conditions should be allowed to interrupt the communication of knowledge, save only those arising from the want of desire to receive, or the want of capacity to comprehend its bearings? The *suppressio veri* and prohibitory edicts against inquiry are fatal to the healing arts. When these interpose, the cause of Medical science ceases at once to be the cause of humanity. What reason can the Pathologist assign why full reports of two recent cases (with minute post-mortem examinations) of pyæmia from cancer, one after an operation, and the other from cancer of the tongue, should have been read at the last meeting of the Medico-Chirurgical Society, and published a few days ago in the March number of the *Edinburgh Medical Journal*, while all notice of Mr. Syme's case is carefully withheld from the Profession?

The Pathologist has the character of being an accurate observer, and the credit of discharging his duties in the most independent and impartial manner; but although by his silence he virtually confirms all I stated in my letter, he has not, as Mr. Syme's substitute, answered one of the interrogatories I put to the Professor of Clinical Surgery. I beg, therefore, to submit to his review the following extracts from two or three, among several other letters, which I have received on the subject from trustworthy persons, one of whom was an eye-witness of the autopsy, and reports the appearances he observed, and I trust if any mistakes or misapprehensions be found, that their statements will receive the necessary corrections.

Let me advert to the averments on two occasions published by Mr. Syme, first in the *Scotsman*, December 21, when he says, "the patient went on very well for nearly a week, when the external wound was quite healed," (the patient only survived the operation a week;) secondly, in his letter in the *Times* of December 22 he writes, "but at the end of a week, when the external wound was quite healed."

1st. Extract from a letter by an eye-witness to the post-mortem examination:—

"The external wound was *not healed*, the only union consisting of slight adhesions at the upper part of the wound (*i. e.* the mental portion). The cut edges of bone were quite dead, though I cannot say whether any separation had commenced. Suppuration was evidently copious. On cutting through the pterygoid muscles, an abscess was opened into, and a good deal of pus discharged. The pharynx did not seem much inflamed. The trachea and bronchi were very much so, and bathed in pus of a thin consistence, dingy colour, and offensive odour. This condition extended down to the minute bronchi. In the substance of the lungs there were several circumscribed purulent collections, some superficial, some deep-seated; a few had not gone on to softening, but presented an appearance which rendered the diagnosis difficult from cancerous deposits. There were, besides, one or two larger patches of yellow softened matter deep in the substance of the lungs, about one inch in length, and half-an-inch broad. Other organs healthy." . . . P. S. "The above is the state of the parts, to the best of my recollection."

Another correspondent writes, that he heard it stated in a conversation between parties directly interested in the autopsy, "that the wound was not healed, and had not begun to heal when the patient died, and that when *sectio cadaveris* was performed, the wound from excision was found open and raw, with a fungoid appearance."

Second extract from a letter of a student, who had applied to the Pathologist for information:—

"I called on the Pathologist to-day, with the view of obtaining information from him regarding the case of excision of the tongue. He stated that he had been applied to by a great many parties for the same purpose, but had *invariably refused showing them his post-mortem book, or giving them any particulars, as he did not wish to get himself into any scrape in the matter.* I did not urge the thing, merely telling him that I had some notes of the case, and as I was not present at the post-mortem examination I was desirous of getting a few particulars for my own satisfaction. *The only thing I got out of him was to the effect, that the man died of pyæmia.*"

The request of this student was most reasonable, and his denial of access to the Pathologist's Report only more strongly demonstrates the necessity of such a document being made patent to all the Infirmary students, the great proportion of whom may, from unavoidable causes, such as attendance on the University classes, etc., be prevented from witnessing the post-mortem examination; but what will be the verdict of the Profession on the conduct of the real custodian of the Report, whose silence regarding it admits but of one interpretation, and that neither a dubious nor a strained one?

I am, &c. JOHN RENTON, M.D.

5, Eastfield, Leith, March 3, 1858.

### BLEEDING IN ARMY MEDICAL PRACTICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—You have given us much interesting information relative to the management and condition of our household troops, but there is one point of great interest—of particular interest at the present moment—concerning which the Profession is quite in the dark. I refer to the Medical treatment of the soldier when attacked by acute diseases. I have always understood, from Army Medical friends, that the traditional system of venesection has been sustained in the army up to the present day in the management of acute inflammations; and certainly the only really orthodox bleeding which I have witnessed for many years past was effected in one of our military Hospitals on the person of a magnificent-looking Guardsman, who was suffering, as I judged from a cursory examination, from acute tuberculosis of the lungs.

We have all been so painfully surprised at the mortality, from acute thoracic diseases, of men in the Guards, that every point which refers to their management becomes of importance; and as the treatment of these disorders must have a great influence for good or for ill over their health, it becomes a matter of real practical value for consideration whether that most potent of all Medical remedies, viz. venesection, if still at this moment actively employed for the cure of the class of diseases above referred to, is wisely used in their case.

The treatment of inflammation by large bleedings has long been notoriously abandoned in civil practice; it is admitted to be not only useless but highly dangerous. Now, if this treatment (as I understand it) is really still exercised in the case of the soldier, it becomes a matter of great interest to us to know what there is in his constitution which exempts him from suffering those ill effects which we see result from the practice of large bleedings in ordinary cases.

Your influence may perhaps obtain for us from some one of our military brethren information on this subject.

I am, &c. W. O. MARKHAM.

Clarges-street, March 9, 1858.

### "GRAHAM'S SAW," IMPROPERLY CALLED "BUTCHER'S SAW."

[To the Editor of the Medical Times and Gazette.]

SIR,—Under the above title a letter from me appeared in your Gazette of the 13th of February, stating the surgical Bow Saw, with double extending screw, and blade jointed at each end, for cutting in a curvilinear as well as in a straight direction, was the invention of Mr. Graham, a surgeon in Northumberland, fully twenty years ago; and that a saw known in London and Dublin as "Butcher's Saw" was identically "Graham's Saw."

In your last Saturday's Journal, that letter is honoured

with a lengthy reply from Mr. Butcher, and a wood-cut representation of his saw, which satisfactorily proves that the "artist's saw" adopted by Mr. Butcher is not the same as that invented by Mr. Graham, but it leaves untouched my statement, that "Graham's Saw" is improperly called "Butcher's Saw." Since reading Mr. Butcher's reply, I have been desirous to ascertain if any circumstances existed to account for an English instrument maker substituting one saw for the other, and I find in the last edition of Druitt's excellent manual a faithful delineation of "Graham's Saw," which in the *index* is called "Butcher's Saw," while in the letter-press it is described as one by Mr. Bullock, of Dublin; this may have inadvertently led to the mistake, or the instrument-maker may have (though very wrongfully) thought himself justified in naming the best saw "Butcher's Saw." It is not, however, the cause, but the fact of the substitution which formed the title of my letter. The under wood-cut is an exact representation of the saw presented by Mr. Graham in 1831-2, to Professor Dr. Lawrie of this city, and the saw itself I forward to you, Mr. Editor, for the fullest inspection.

It will be seen how completely it wrests from Mr. Butcher his "claim to the peculiarly shallow blade, and the power of rotating to any angle, and fixing it so;" also the peculiar setting of the blade, and its pointed extremities permitting of being passed behind bones." The saw itself "demonstrates its adaptiveness to all resections and amputations," for such operations it was invented,—and the handle in a line with the blade" is the only point of difference remaining.

I have no motive in making this claim for Mr. Graham, other than the desire that every inventor should receive the merit of his invention. I am exceedingly sorry for occupying so much space in your highly useful Journal, and beg you to excuse it on this occasion.

I am, &c.

WILLIAM B. HILLIARD,  
Instrument Maker to the  
Glasgow Royal Infirmary.

### PROSTITUTION AND VISIONARY PHILANTHROPISTS.

[To the Editor of the Medical Times and Gazette.]

SIR,—As I cannot for one moment suppose any intention on your part to "put me down," or to "pooh! pooh!" the subject of Prostitution altogether, I take refuge in the idea that press of business has precluded you from more than a very superficial view of my little work upon this subject. Had your labours or inclinations permitted more, you would have found that the domiciliary visitation was not proposed by me, was no "special succedaneum" for anything, any place, or anybody. You might have seen that far from being of an arbitrary or tyrannical turn, I endeavoured to demonstrate the vanity and futility of all attempts at suppression; and that I proposed to legalise the registration and right of entry into disorderly houses in the interest of public liberty. You might have read as follows: "Few will deny that it should be competent to the community to suspend, in its own interest, the inviolability of the domicile where the Englishman's castle is so grossly perverted into a battery against English morality, as in the case just recited (of a murderous assault in a brothel)."

You might have found in every page fair evidence that that I am more radically affected with Mayne-o-phobia than even perhaps yourself. You might have seen that I took up arms against the little prejudices of my neighbours of Portland-place, which might have led them, if uncontrolled, to the verge of police tyranny, and you would have less surprised me had you taxed me with pernicious lenity, instead of with Terrorism.

My suggested "special service of constables," was the most effective cure for the Portland-place and Waterloo-place nuisance I could then suggest, and I took refuge in it as being the only one not tyrannical or incompatible with public liberty. It remains now, as it was then, the only suggestion for regulation of the *pavé*, as far as those districts are concerned, that will hold water—and with all deference to you, I shall live to see it adopted. A proctorial prostitution police, flagrant even in uniforms, might, I insist upon it, be placed on duty by the authorities to prevent an accumulation of harlotry on a given area, without the slightest interference with "the free spirit of our country's laws." The commonwealth has as surely the run of the *trottoir* for its employes, as for its individual members; and the "flagrancy" which seems to stink in your nostrils is very antithetical to the mouchardism of Paris wherewith you confound it. The only single point upon which all writers on Prostitution appear to be agreed is, the positive nuisance of the bands of foreign women who infest the localities above mentioned. Their dispersion is by all insisted upon as devoutly to be wished—the special police force of my suggestion is the very thing to effect it—not by *dragonnades*, but by an appeal to their pockets; yet you unluckily fasten upon this as an advocacy of tyranny, not as an alternative; as a sweeping measure, or, as you say, *succedaneum*, plotted against all prostitution, not as an experiment suggested for one or two corners of the metropolis.

How ingeniously, again, have you dealt with another of my ideas, which you would characterize, I suppose, as my *succedaneum* for syphilis. "Syphilis," you say, "being an infectious disease, demands unusual facilities for its cure, and our Hospital accommodation runs disgracefully short. Let us, therefore, he (your humble servant, I presume) says, establish a 'London Female Sanitary Society,' a 'Benefit Club for Prostitutes.'"

Now I will no more at present enter into detail of this proposed association, but remark, by the way, that I see no reason why even prostitutes should be held unworthy of advice and encouragement to cleanliness and economy. I can have only space to refer you to page 152 of my work, where it may fully appear that neither sanitary society, nor visitation, nor relief fund, is any *succedaneum* of mine, but that they are merely proposed as "last alternatives."

The preceding 25 pages are devoted to the argument (possibly old to you and me, as I said before, but surely to the public novel), that the care of the syphilitic should devolve upon the public; and pp. 162 to 166 are allotted to the alternatives.

You ask the reader—"Does the author of the scheme really believe that he will ever find a body of Medical men who will assist him in carrying out such things as these?" Indeed he does believe that were the alternative forced upon the public he would find such aid. Before propounding my scheme, I put myself in communication with the leading General Practitioners, who at present are consulted by the "unfortunates of London." Yes, Mr. Editor, be it known to you that even the London harlot is attended, has been attended, and will continue to be attended by the Medical man, aye, by Medical men of large practice, highly conscientious philanthropic persons, ornaments to our Profession. They will tell you, if you possess their confidence, that as long as the poor fallen woman has money she fairly remunerates her Medical adviser; when steeped in poverty she still claims his advice, and as she rarely pleads in vain, perchance recovers: and many a story could our Profession tell—as pendants to that lately told in the *Times* of the brickmaker's daughter—of women who are now attended in Belgravia by the same kind-hearted Doctor who was first called to see them when they lived in Norton-street, or Arundel-court, Haymarket.

I have tried, Sir, as you say, "as author, orator, and healer, to make my name conspicuous in the modern annals of prostitution," and I am glad to say that your admission of my competency to speak upon this subject seems to be warranted by the opinion of a sufficient majority of social reformers, lay and professional. I "have told some good old truths," Sir, as you say again, so appropriately as to give what were platitudes to you and me the air of refreshing novelties to the outside public. When I first took up the subject there was not so much as a paragraph open, even in the cheapest of the cheap organs, for gratuitous contributions on the subject; but when I observe the avidity with which

the physiology of harlotry has been of late caught up by editors, worked up by the gentlemen of the press, and devoured by a million readers, I have the vanity to congratulate myself that I have helped materially to find for some a new industry, for others a new sensation, and for the public some advantage. I am, &c. W. Acton.

46, Queen Ann-street, Cavendish-square.

### POISONING BY *CENANTHE CROCATA*.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last week's number (March 6th) are related by Dr. Grahame two fatal cases occurring after eating the roots of *Cenante crocata*.

My reason for addressing you is on account of the author of the paper confounding this plant, *Cenante crocata*, Anglice, Hemlock water dropwort, with wild celery, or *Apium graveolens*.

It may be a question which of the two plants was really gathered and eaten in the case treated by Dr. Grahame. The probability is, that, as stated by him, it was *Cenante crocata*, which is not, however, wild celery. Sir James Smith (*English Flora*, vol. ii. p. 76) says of *Apium graveolens*, or wild celery, "The seeds and whole plant in its native ditches are acrid and dangerous, with a peculiar strong taste and smell. By culture it becomes the mild and grateful garden celery."

*Cenante crocata*, or Hemlock water dropwort, is, like *Cicuta virosa*, a plant growing in similar wet situations, but of much rarer occurrence; undoubtedly a very poisonous plant, as Dr. Grahame's cases but too well prove.

In Dr. Hornton's *Family Herbal*, p. 313, are related several fatal cases from the use of *Cenante crocata*, which in some had been mistaken for wild celery, and in others for water-parsnip (*Sium nodiflorum*).

As the subject is of considerable practical importance I thought these few remarks might not be unacceptable, either to you or to Dr. Grahame.

I am, etc.

JOHN WINDSOR, F.L.S. etc.

65, Piccadilly, Manchester.

### REPORTS OF SOCIETIES.

#### HARVEIAN SOCIETY.

THURSDAY, FEB. 4, 1858.

DR. HAMILTON ROE, President, in the Chair.

DR. FULLER exhibited

#### A FIBRINOUS CAST OF THE PHARYNX,

Ejected by a female patient suffering from diphtheritis. It was above four inches in length, tubular in form, and remarkably firm in texture. The patient recovered before the expiration of a week from the date of her seizure.

DR. HEADLAM GREENHOW related a case of diphtheritis, which he believed to be of similar character to the disease described by Bretonneau of Tours, and identical with the malignant sore throat which has recently prevailed in Essex and other parts of this country. The child, who was the subject of the case, died rather suddenly, and on examination after death, the pharynx and tonsils were found covered with a loose, pliable, granular exudation; the membrane below the exudation was unhealthy and aphthous, especially on and near the tonsils. This form of exudation extended only to the rima glottidis, but the larynx and first inch and a half of the trachea were lined with a tube of croupy false membrane, which adhered to the subjacent tissue only by a few points.

MR. HAYNES WALTON then read a paper on

#### SOME FORMS OF IMPAIRED VISION, AND ON THE USE OF THE OPHTHALMOSCOPE.

The author commenced by observing that almost every state of impaired vision, not accompanied with palpable objective symptoms, was, at no distant period from the present, attributed to amaurosis. More recently it had been supposed that an unhealthy choroid coat was productive of many of the symptoms of amaurosis, and choroiditis became a fashionable disease. But Asthenopia, or an in-

capability of sustaining the eye in a state of adjustment to near objects, is a distinct and not uncommon affection. The chief characters of this affection were fatigue of vision after employment of the eyes on any of the accustomed pursuits, even such as light reading and doing fancy-work, although it is more common in persons who are engaged in trades requiring minute and long continued exercise of sight. Afterwards, confusion and obscurity of vision supervene, sometimes attended with heaviness in the head, or actual headache. A momentary remission is afforded by shutting the eyes or looking at distant objects, and rest for a day or two is always attended with much benefit. There is not necessarily any intolerance of light, but in the large majority of cases a bright day is rather disagreeable, and bright artificial light is trying. There is usually no evidence of a deranged state of the bodily functions, but a general feebleness of system is most commonly present, and the class of persons who are most subject to the affection are girls who are thin and ill-fed, and who lead sedentary lives. In the treatment of this affection, rest of the eyes is often very beneficial in the incipient stage, together with a tonic system to support the general health; and in addition to ordinary constitutional remedies, the use of the cold bath, especially cold sea-bathing, and the employment of the eye-douche are to be recommended. The ophthalmoscope has much improved our means of diagnosis, and dispelled many doubts respecting amaurosis and choroiditis.

Mr. Haynes Walton then explained the principle of the instrument, and in the course of the evening he exhibited its use upon a healthy and a diseased eye.

### HUNTERIAN SOCIETY, FEB. 27.

Dr. Peacock read the notes of four cases of chronic pleurisy which had opened through the lungs. The first of them was that of a young man, 23 years of age, a sailor, under his care at St. Thomas's Hospital, in 1864. He was taken ill on ship board, when on the return voyage from Calcutta, and when admitted into the hospital had the usual signs of a pleuritic effusion in the right side. He had then been ill about three weeks, and after he had been in the hospital for a month, he suddenly began to expectorate large quantities of matter after severe fits of coughing. These attacks continued to recur at intervals for nearly a month, and there was evidence of the presence of some air in the pleural cavity. He recovered, and was discharged, after about ten weeks' residence, and was seen some time after quite well. Indeed, he had resumed his occupation. The second case, that of a young man 25 years of age, who was a patient at the Victoria-park Hospital for diseases of the chest, in 1855. In his case, the matter began to be expectorated while the evidences of the effusion in the pleura were subsiding, and the side was undergoing contraction. There were signs of an escape of air into a limited portion of the pleural cavity. The patient was in the hospital four months, and was discharged quite well. The subject of the third case was a clergyman, 30 years of age, who was seen by Dr. Peacock in 1855. About six months before that time he was seized with pain in the right side, and other symptoms of pleurisy, and six weeks after suddenly expectorated matter. When seen he was recovering, and there were evidences of pleurisy undergoing cure, and he subsequently got quite well. The last case was that of a patient at the Royal Free Hospital in 1849, while Dr. Peacock was connected with that institution. He was 30 years of age, and had laboured under symptoms of affection of the chest for six months before his admission, which had been recently much aggravated. When admitted he presented the usual signs of an extensive effusion in the left pleural cavity, and four days after he was seized with a violent cough, followed by copious expectoration of purulent matter. He was greatly relieved, but was removed from the Hospital before his cure was complete. In the last two cases there was no evidence of any air having entered the pleural cavity while they were under observation. The inferences drawn by Dr. Peacock from these cases were—1. That the entrance of air into the pleura is by no means a necessary result of the establishment of communications between the pleural cavity and bronchial tubes, and that we may

safely infer the existence of such a communication when a person who presents the usual signs of a large pleuritic effusion is suddenly seized by violent fits of coughing, followed by the expectoration of a large quantity of matter containing little or no air, and when similar attacks recur at longer or shorter intervals. 2. That the desirableness of practising paracentesis thoracis in cases of pleuritic effusion in which communication has taken place with the bronchial tubes, must be decided by similar considerations to those which would influence us in having recourse to the operation in any other cases. He would not himself be disposed to recommend the operation, except when the accumulation in the pleural cavity was probably very large; when the difficulty of breathing was so urgent as to threaten immediate suffocation; or when appropriate treatment had been tried without success. He expressed his opinion that there was a tendency to under-estimate the advantage which attended the employment of the ordinary treatment in cases of chronic pleurisy, and stated that he had seen absorption readily effected in cases which at first presented little prospect of that result being accomplished.

A discussion ensued on the reading of the paper, in which Dr. Barlow, Dr. Gull, and Mr. Hutchinson took part.

### SELF-SUPPORTING DISPENSARIES.

A meeting was held on Wednesday, March 10, at the Grosvenor-place School of Medicine, to discuss the question of "Self-supporting Dispensaries." The Earl of Ducie presided. In opening the proceedings, he said he believed that the scheme they had to consider was a good one, as by its means the poor might be taught the useful lesson of depending in times of sickness upon their own provision and foresight, instead of having recourse to charity for Medical aid. That, no doubt, was one of the advantages which would flow from its adoption; but still there were, it could not be denied, many difficulties and obstructions in the way of it. It would, at all events, teach the poor the benefits of amalgamation and co-operation, which, among the rich, were perhaps already carried to too great an extent, as in the establishing of clubs. It was a principle, however, which had for the most part failed among the poor. The most successful instance of its working probably was to be found in the model lodging-houses; but even there the direction of the whole thing was in the hands of educated men. On the other hand, the local benefit clubs had as a rule failed, simply because the management of them was in the hands of the people themselves. Another obstruction to the establishing of self-supporting Medical institutions in London was, that there was no room for them, the ground being preoccupied by 110 hospitals and dispensaries, where the poor could get, free of cost, that Medical aid for which they would have to pay at the proposed Self-supporting Dispensaries.

Mr. Smith of Southam then explained his views as to the Self-supporting Institutions. He explained the advantages of such institutions under several heads. The plan had the most useful influences on the poor; it taught them to be provident; it taught them self-confidence and self-respect. It enabled the upper and middle classes more effectually to co-operate with the lower classes in the cause of improvement and progress. The plan was advantageous to the Medical Profession. Here Mr. Smith detailed the results of experiments on his scheme at Northampton, Coventry, and other places, showing by reference to the returns of these Institutions that while this Dispensary has in no way interfered with the incomes of Medical men from private patients, it brings in considerable sources of income to the Profession, from persons who can pay a small sum for professional services, but who would otherwise receive such professional services gratuitously. In the conducting of these Dispensaries every medical man should take a part. Each head of a family on being found a proper person for being enrolled should have the privilege of selecting his own medical man. Medical men should only prescribe, not supply medicines, for dispensary patients. Mr. Smith stated that with the sum of £10,000 he could set on foot in London 20 Self-supporting Dispensaries, each having 20 medical officers, and each medical officer receiving £300 per annum from the contributions of the poor.

An animated debate took place, in which Lord Ducie, Dr. Ogle, Dr. Leared, Dr. Richardson, Dr. Powell, Dr. Chapman, Mr. Spencer Wells and Mr. Propert took part. Dr. Richardson, as Honorary Secretary of the Grosvenor-place School of Medicine, explained that the Faculty of Lecturers, while they had been happy to hear in their theatre Mr. Smith's exposition of the self-supporting scheme, did not consider themselves pledged to support or oppose Mr. Smith's views. They wished simply in a liberal spirit to give Mr. Smith the opportunity of explaining his plan to a London audience. Towards the end of the meeting Mr. Spencer Wells moved as an epitome of the feeling of the meeting the following resolution:—

"That the meeting having heard Mr. Smith's explanation of the principle of Self-supporting Dispensaries in operation at Coventry, Northampton, and other places, was of opinion that it was one which might be extended throughout the country; and would suggest that Medical practitioners in different districts should meet together, and, by establishing Self-supporting Dispensaries, should endeavour to correct the notorious existing abuses in Medical institutions."

The motion was seconded by Dr. POWELL, and unanimously carried. Votes of thanks having been voted to Lord Ducie and Mr. Smith, the meeting separated.

### MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 5th inst. :—

BOWES, JOHN, Workington, Cumberland.  
DAVISON, JOHN MARCHANT, Islington-green.  
GIBSON, THOMAS, Kirkby-Stephen, Westmorland.  
HAWKINS, JAMES S., Colet-place, Commercial-road.  
NAPIER, WILLIAM D., George-street, Hanover-square.  
NEWLAND, PETER FREDERICK, Dublin.  
O'CONNOR, MICHAEL JOHN, Manchester.  
SCANLAN, FITZGERALD EDWARD, Army.  
SEPHTON, RICHARD, Kenyon, near Manchester.  
WARD, JOHN DOXON, Manchester.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the Science and Practice of Medicine, and received Certificates to Practise, on March 4, 1858:—

BOWER, JOSHUA, Wilmslow, Cheshire.  
CHREEMAN, JOHN, Lewes, Sussex.  
DAY, HENRY ARUNDELL, Bristol.  
GOLDSMITH, JOHN, Hambledon, Hants.  
HOGG, FRANCIS ROBERTS, Army.  
HUGHES, HUGH, Bethesda, North Wales.  
LIDDON, WILLIAM, Taunton, Somerset.  
PARK, MUNGO, Berwick-upon-Tweed.  
TOMPSON, CHARLES AUGUSTUS JAMES, Dudley.  
WOAKES, EDWARD, Luton, Beds.

### DEATHS.

**BLAKE.**—February 28th, at the Grove, Camberwell, R. Blake, M.D. (R.N.), aged 76.

**CHALK.**—On board Her Majesty's troop-ship Southampton, fourteen days' sail from Kurrachee, from London to that port, Hammond Chalk, M.R.C.S., Eng., and L.S.A., who died suddenly, aged 47 years, from diseased heart consequent upon rheumatism. His rare skill in the practical details of his profession, and kindness of disposition, made him an invaluable and never-failing friend to the young practitioner. These, together with the Christian fortitude with which, for many years, he endured acute physical suffering and mental troubles of no ordinary character, rendered him an object of respect and admiration, whose loss will be severely felt by his numerous friends and sorrowing family.

**FINLEY.**—It is our painful duty to record the death of David Luke Finley, aged 27, Surgeon of the Royal Mail Steam Company. The deceased gentleman had been seven years in the Company's service, during which period he had witnessed no less than three visitations of yellow fever in the West Indian Islands. He was one of the most ardent investigators into the nature and treatment of the disease to which he succumbed; and had himself written a pamphlet, embodying his own practical views on the subject. On the 15th of February, the first man seized on

board the "Parana" was a man named Witt, a scullery-man, and Mr. Finley was indefatigable in his attention to him until the 18th of the month, when, while at the dinner table, he was himself suddenly seized with the symptoms of the disease, and left immediately, took a warm bath, and had recourse to one of the most approved methods of treatment under the superintendence of Mr. Murphy, surgeon, R.N., who was on board, on his way home as a passenger. On the third day from the attack he was seized with black vomit, and lingered on to the 25th February, when he fell a victim to the deadly disease. Poor Witt died on the 21st, after having had black vomit. Mr. Murphy, his attendant, of whom it is impossible to speak too highly, who had been seven years in attendance at the Jamaica Hospital, and had been a shrewd observer of all that is practised in the treatment of the disease, was in attendance upon Mr. Finley night and day. The melancholy death of Mr. Finley, who had been married but twelve months, painfully reminds us of the significant warning we gave, in a recent number of this Journal, to Surgeons who had in contemplation the idea of serving the Royal Mail Steam Packet Company. We hope that our warning has not been without its results.

**HAYMAN.**—On 28th February, at the house of his son, Henry Hayman, Esq., M.R.C.S.E., Ottery St. Mary, Charles Hayman, Esq., in the 78th year of his age. Mr. H., formerly Surgeon, R.N., practised for more than half a century at Axminster, Devon, where he was highly esteemed by all who knew him. He has left a large family to mourn his loss. Four of his sons are members of the Profession, and his third daughter is married to Dr. Maddock.

**HELE.**—March 3, at Plymouth, John Hele, of Ashburton, Devon.

**ROULSTON.**—At Albion-house, Low Harrogate, John Roulston, M.D., St. Andrews, 1851, M.R.C.S. Eng., and L.S.A. 1851, late House-Surgeon, Leeds General Infirmary, aged 30.

**TRAVERS.**—On the 6th inst. at his house in Green-street, Grosvenor-square, Benjamin Travers, F.R.S., Serjeant-Surgeon to the Queen, etc., aged 75.

**DIPHThERITE.**—At a late meeting of the Medical Society of London, Dr. Camps read a paper "On the lately prevailing Diphtheritic Affection." The author stated that in his opinion medical practitioners exhibited a great want of precise knowledge as to the true nature of this disease. His own attention was drawn to the subject by observing, in one of the quarterly returns of the Registrar-General, a most unusual number of fatal cases of croup, stated to have occurred in a rural district with which he was personally acquainted, and he is inclined to believe that many of these cases, described as croup, were in reality diphtheritis. (This form of disease, both here and in France, has more commonly assumed an epidemic than a sporadic character, and Dr. Camps was inclined to believe that many of the cases of severe throat disease, which occurred lately at Boulogne, were instances of epidemic diphtheritis. All the severe cases which have come to the knowledge of the author occurred in rapid succession and in rather close proximity as to place, many having arisen in the same house, and others in the same town, village, or immediate vicinity. The type of the disease, in its severer forms, he regarded as being essentially asthenic, attended with diminution of vital force. The characters of the disease, as described by Bretonneau, were then briefly detailed, together with the symptoms and general features presented by the present epidemic, as recorded by observers in various parts of the country. Reference was also made to an extensive series of cases which occurred in Haverfordwest in 1849, and which were recorded by Mr. Brown, of that place, in a paper published in this Journal in the year 1850. During that epidemic that gentleman had attended two hundred cases, forty of which proved fatal. From all the facts which Dr. Camps had been able to collect, he was induced to conclude that the disease now prevailing was very analogous to, if not identical with, that described by M. Bretonneau as diphtherite; that it was mainly of an asthenic type, and was characterised, in the severer cases, by the formation of plastic pseudo-membranous exudations; that it is primarily pharyngeal in its seat, and not laryngeal, except secondarily and by complication; that it differs from stomatitis in intensity or degree, rather

than in kind, and that its chief point of difference from the malignant sore throat of scarlatina is to be found in the tendency to the formation of plastic exudations; that it often possesses the characters of an epidemic; and that its adynamic type clearly indicates the mode of treatment which ought to be adopted. The treatment should be topical and general; the former consisting in the application of a strong solution of nitrate of silver to the parts affected, or a similar application of hydrochloric acid or chlorine; the general treatment should comprise the administration of chlorate of potash, with chlorine, or a combination of cinchona bark, or its alkaloid, with the mineral acids. In the severe cases, calomel should be given in repeated doses, until ptyalism is produced, and emetics in the early stage have been administered with good effect; and the powers of the patients should be supported by wine, stout, beef-tea, and other invigorating means.

**PROSTITUTION IN AUSTRALIA.**—At the time our journals at home are discussing more frequently than usual "the great social evil" of our large cities, the same sad topic is exciting precisely the same attention, and leading to the same remedial suggestions, at Melbourne. Public meetings have been held in the colony, and deputations have had interviews with the Governor, with a view to the adoption of means for the repression of vice. The *Argus* states, that female prostitution prevails throughout the Australian colonies "to a frightful extent."

**ORDER OF THE MEDJIDIE.**—WHITEHALL, March 2, 1858. —The Queen has been pleased to give and grant unto the undermentioned Officers Her Majesty's royal license and permission that they may accept and wear the insignia of the several classes of the Order of the Medjidie attached to their respective names, which his Imperial Majesty the Sultan hath been pleased to confer upon them, as a mark of his Majesty's approbation of their distinguished services before the enemy during the late war, or as having been actually and entirely employed in his Majesty's service, and that they may enjoy all the rights and privileges thereunto belonging, viz:—Officers of the British Army.—Third class—Insp. Gen. of Hospitals, Sir J. Hall, K.C.B., M.D. Fourth class—Insp. Gen. of Hospitals, W. Linton, C.B., M.D., A. Cumming. Dep. Insp. Gen. of Hospitals, D. Dumbreck, C.B., M.D.; J. Forrest, C.B., M.D.; R. Dawson, and A. S. Macdonald. Officers of the late Turkish Contingent.—Inspector General of Hospitals, D. McPherson, M.D. Deputy Inspector General of Hospitals.—J. Vaughan. First Class Staff Surgeons—Major, Ainger, R. Paton, L. Hynde.—Fifth class.—2nd Class Staff Surgeons, C. H. Johnson, J. H. Keeling, A. A. McDowall, C. McDowall, A. Irvine, G. S. Sutherland, J. Williamson.—Assistant Surgeons, E. Edwards, F. L. Gunn, W. W. Coleman.

**THE SARDINIAN MEDAL.**—The following Officers of the Royal Navy have been selected to receive the War Medal awarded for Military Valour by His Majesty the King of Sardinia to the British Naval Forces engaged on shore in the Crimea during the late war.—Surgeons, D. J. Duigan, M.D., and G. Mason, M.D.

**NAVAL AND MILITARY SURGERY IN CHINA.**—The *Times* correspondent says:—"Our loss in killed and wounded during this short siege does not amount to more than 96 English and 34 French, and of these the wounds are under the average severity. The surgeons say that this is to be accounted for by the want of propulsive power in the Chinese weapons. At an early hour this morning (Jan. 15) I visited the Hercules hospital-ship in this harbour. Dr. Burns and Dr. Smart, with their assistants, were already at their duties; the desperate cases are very few, and the men are in the enjoyment of all the care and comfort which can alleviate their pain and expedite their recovery."

**THE FRENCH MILITARY HOSPITALS.**—The large new Military Hospital at Vincennes is now ready for the reception of patients. The erection of military hospitals goes as far back as Henry IV., who established the first at the siege of Amiens in 1597, wherein Sully declares the patients were as well treated and cared for as if they had been in their own homes. This establishment was, however, only *ambulant* and temporary; and the first stationary hospital was founded at Pignerol by the Cardinal Richelieu. Louis XIV. imparted a stability and an extension to these establishments commensurate with the importance of the military operations of his epoch. To him we owe the first permanent hospitals in cities of war,

and he never had a place fortified without ordering the construction of a hospital. At a later period came the magnificent erection of the Invalides; and under the succeeding reign the Duke of Biron founded at Gros Caillon a hospital for the French guards, whose colonel he was. This is a very important hospital at the present time. The monastery of Val-de-Grâce becoming national property in 1790, was converted into a military hospital by a decree of the Convention in 1793. The Roule hospital was founded in 1848, and is now about to be replaced by the Vincennes hospital.

**ARTIFICIAL ROSE WATER.**—M. Rudolf Wagner has given us a pretty little prescription for obtaining artificial rose-water. The products of the spontaneous decomposition of salicylate of potash are generally characterised by a strong perfume of roses. This salt is quickly obtained by decomposing salicylate of methylen (which can be bought under the name of *essence of gaultheria*), by caustic potash. In this manner a mass of crystals, consisting of salicylate of potash, are precipitated, and the supernatant solution has a strong odour of roses. This liquid gives by distillation an *eau de roses* of a very fine quality, which constitutes a delicious perfume.—*Illustrated Inventor*.

**PHOTOGRAPHIC POWER OF THE MOON AND PLANETS.**—A few years ago it was thought that the moon emitted neither chemical nor calorific rays. More careful experiments have, however, shown the inexactitude of this opinion. Melloni was fortunate enough to observe by means of a lens of three feet in diameter, the most satisfactory indications of an elevation of temperature during different changes of the moon; and photographs of our satellite prove that it reflects also chemical rays in abundance. It is well known that the sun-light reflected from the moon is in all zones more feeble than the sun-light which is reflected by a white cloud in the day time. Some time back astronomers endeavoured to ascertain the different intensities of the light of our satellite during its different phases. Lambert has shown by photometrical experiments, that the light of the full moon is to that of the first quarter as 66 : 42, or nearly as 3 : 2. M. Secchi, of Rome, has just demonstrated that the chemical action of the moon on photographic preparations is, in the same circumstances as 3 : 1. The planet Jupiter, although five times the distance from the sun, is photographed more easily than is the moon, and in less time. The chemical force of Jupiter's light is then considerably superior to that of the moon. It has been known for a long time that the planet Jupiter can be magnified without losing so much light as the moon,—in other terms, when the moon's disc is extremely magnified, its light becomes very feeble in comparison to the loss of light by Jupiter under the same circumstances.—*Illustrated Inventor*.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, March 6, 1858.

### BIRTHS.

Births of Boys, 869; Girls, 775; Total, 1644.  
Average of 10 corresponding weeks, 1848-57, 1675.

 A Treatise on Electricity. By A. de la Rive. Vol. III. London: 1858.  
 Journal of Practical Medicine and Surgery. No. 1. Paris: 1858.  
 Clinical Lectures on the Principles and Practice of Medicine. By J. H. Bennett, M.D. F.R.S.E. Second Edition. Edinburgh: 1858.

## TO CORRESPONDENTS.

*Dr. Whitehead's* case of Diphtherite shall appear next week.  
*Mr. Wright's* notice of the expected operations at the Westminster Hospital on Tuesday last arrived too late for insertion last week. Such notice, should be at the office before 1 o'clock on the Thursday before publication.  
*Medicus.*—Both the works named are supposed to be addressed to the Profession, but they are clearly intended for popular perusal.  
*Mr. Crookes.*—Thanks.  
*Dr. W.*—The Hospital Pharmacopoeia is not forgotten; but it is necessary to vary our dishes.  
*Mr. Hughes's* explanation of the muco-purulent discharge in the cases he relates is in all probability correct.  
*R.S.*—It is certainly not consistent with the honour of our Profession for any member of it to be in possession of a valuable recipe, and to keep it secret.  
*Dr. Ogilvie, Alexandria.*—The letter has arrived, but not the case.  
*A Constant Reader.*—The request shall be complied with.  
*Dr. Brown, Chatham.*—The typographical error was corrected in the succeeding number.

## THE NEW AND FATAL FORM OF SMALL-POX IN ASIA MINOR—RE-VACCINATION OF OUR INDIAN FORCES.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—As no doubt the above new epidemic will in due course of time find its way to the East Indies, I would humbly suggest, through your columns, (as the sanitary state of the army is now the leading topic,) that all our troops, European and native, out there, should be re-vaccinated by troops or companies, at the earliest possible opportunity. I would further recommend, that all soldiers that may be hereafter despatched to that country should be re-vaccinated "on the voyage out," or immediately after landing. The French Government, "upwards of two months since," despatched a physician to Asia Minor, to study this new form of small-pox! England might emulate her ally by sending out a Medical commission at once. Before this disease appeared, you may remember, our allies ordered every soldier or sailor entering the hospital to be re-vaccinated.  
 I am, &c.  
 March, 1858.

JUVENIS.

*Pro Bono Publico.*—Wanted the formula for Phosphate of Zinc. (Our correspondent adds, "It is to be regretted that Dr. Barnes having used it 'in every case' with success for the last two years, should only just now publish it.")

*Scurvy in the Navy.*—*Juvenis* states that a tablespoonful or more of powdered charcoal to a gallon of lime-juice, will not only preserve it for a length of time, but improve its antiscorbutic properties. During the voyage the charcoal may be replaced by a fresh quantity; in order to do so the lime-juice must be filtered.

## THE SALE OF MEDICINES.

## TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Of all the numerous propositions for rendering the Profession of Physic "respectable," that recommended in your number, March 6, seems the most extraordinary. Some short time ago it was proposed to tax us annually £6 per head to make us "respectable," and now "Medicus" wishes a statute framed, to fine us if we exercise our right as Apothe-

caries in dispensing our own medicines. He can know but little of country practice, when he says, that any place which can support a Surgeon can support a Druggist. Will it add to a Surgeon's respectability to make a patient send at midnight ten or more miles for physic to the grocer-druggist of the village, when by carrying a few drugs in his gig or pocket he might have saved hours, which often includes the life of the sufferer?

I sus; set the patient would prefer the attendance of a man of less statutory "respectability," and more humanity and common sense. If Medical men of the present day are not equally "respectable" with their Continental brethren, they are not to be made so by Act of Parliament.

The course recommended is open to Medicus, but why try to force others to adopt so very inconvenient a course just to humour his whim?  
 March 9, 1858. I am, &c. LIBERTAS.

*A Correspondent* informs us that the following circular has been distributed indiscriminately in Liverpool:—

"Dr. Pollock, who has been Resident Surgeon to the Liverpool Dispensaries for more than three years, has removed from 46, Park-place, to 58, Netherfield-road North.

"P.S.—Fees to the Working Classes moderate, and advice gratis to the poor on Mondays and Thursdays from 9 to 10 a.m."  
 "February, 1858."

Papers by Dr. Robinson, Newcastle, Mr. Z. Laurence, Mr. Musbet, Mr. V. Jackson, Mr. Field, Dr. Halford, Mr. Welford, Mr. Newman, Dr. Byrne and Dr. Sylvester, are in type, and shall appear as soon as possible.

## COMMUNICATIONS have been received from—

Dr. SYMONDS, Clifton; Mr. PAOET; Dr. A. P. STEWART; Dr. G. JOHNSON; Dr. MARKHAM; Dr. A. CLARK; Mr. GAY; Dr. OGILVIE, Alexandria; Mr. BAKER BROWN; Dr. McWILLIAM; Mr. ACTON; Mr. GAMGET; Mr. WRIGHT; Dr. WHITEHEAD, Boulogne; Mr. PARSONS; Dr. BARNES; Mr. EVANS; Mr. SANSON; Mr. WALTERS; Dr. MADDOCK; Mr. CROOKER; Dr. SHARPE; Dr. STILWELL; Mr. MAUNDER; Mr. RIVERS; Mr. C. TAYLOR; SECRETARY, GENERAL BOARD OF HEALTH; Mr. HILLIARD; Mr. McDERMOTT; REGISTRAR-GENERAL; Dr. BROWN, Chatham; Mr. WRIGHT; LYNX; LIBERTAS; Dr. CARNLEY; Dr. ROGERS.

## APPOINTMENTS FOR THE WEEK.

## March 13. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's, 2 p.m. Charing Cross, 1 p.m.  
 ROYAL INSTITUTION, 3 p.m.: Professor Bloxam, "On the Chemistry of the Elements which circulate in Nature."  
 MEDICAL SOCIETY, 8 p.m.: Mr. Hancock, "Cases of Punctured Wounds of the Lungs and Stomach, with Remarks."  
 ROYAL COLLEGE OF SURGEONS, 4 p.m. Professor Busk, "On the Invertebrata."

## 15. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 3 p.m.  
 ROYAL INSTITUTION, 3 p.m.; Professor Huxley, "On Biology."

## 16. Tuesday.

Operations at Guy's, 1 p.m. Westminster, 2 p.m.  
 ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Biology."  
 PATHOLOGICAL SOCIETY, 8 p.m.  
 ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."

## 17. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m. Orthopaedic Hospital, 3 p.m.  
 ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Lumsden Lectures—Dr. Tweedie "On Fevers."  
 MICROSCOPICAL SOCIETY, 8 p.m.

## 18. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
 GROSVENOR PLACE SCHOOL MEDICAL SOCIETY, 7½ p.m.: General Meeting.  
 ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."  
 CHEMICAL SOCIETY, 8 p.m.  
 LINNEAN SOCIETY, 8 p.m.  
 ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."  
 MEDICAL SOCIETY OF KING'S COLLEGE, 8 p.m.: Annual Meeting.

## 19. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.; Great Northern, 2½ p.m.  
 ROYAL COLLEGE OF PHYSICIANS, 4 p.m.; Lumsden Lectures—Dr. Tweedie, "On Fevers."  
 ROYAL INSTITUTION, 3½ p.m.; Mr. Henry Thomas Buckle, "On the Influence of Women on the Progress of Knowledge."  
 WESTERN MEDICAL AND SURGICAL SOCIETY, 8 p.m.: Dr. Arlidge, "On the Prolongation of the Menstrual Period."

## EXPECTED OPERATIONS.

Westminster Hospital.—The following operations are expected on Tuesday next, at 2 o'clock:—  
 Amputation of thigh; talipes valgus; stricture of urethra (2 cases); by Mr. Holt. Wutzer's operation for radical cure of hernia; by Mr. Holt.

Notice to the Medical Profession.

DR. J. COLLIS BROWNE'S

(M.R.C.S.L., Ex-ARMY MEDICAL STAFF)

C H L O R O D Y N E.

(Entered at Stationers' Hall.)

MEDICAL PROPERTIES—Anodyne, Diaphoretic, Sedative, Astringent, Antispasmodic, Diuretic.

A few Extracts of Medical Reports are furnished in testimony of the exceeding value of this New Remedial Agent.

"The following extract from a letter by Dr. SHORRHOUSE, (late of the Metropolitan Convalescent Hospital) of Carshalton, to a Medical friend in the North of England, is published by permission:—

"And now, my friend, about 'Chlorodyne'—the infallible and incomparable Chlorodyne! The best idea I can give you of my estimate of its value will be in the fact, that I have within the last fifteen months used 160 ounces of it, and, as each ounce contains about fifty adult doses, I have given at least 8000 doses. This is what I have administered myself, and is altogether independent of a large quantity which I have prescribed, and the patients have procured for themselves. It is, as I said before, a remedy quite unique, and its effects totally dissimilar to those of opium or any other English medicine. It requires some little management in its administration, so as to ensure its best effects. Out of the many hundreds of patients for whom I have prescribed it, I have found it disagree with but three.

"Its mode of action is that of an astringent in suppressing hæmorrhage and diarrhoea; an anti-spasmodic in colic and all forms of spasmodic cough; an anodyne in allaying pain and excitement, and producing tranquillity and a most heavenly state of repose.

"The cases (among others) in which I have employed it have been twelve cases of phthisis; eight of these patients had been examined by other Medical men, and had been regarded as genuine cases of consumption, so that the nature of the disease does not rest upon my testimony alone. They were all well-marked cases: for I do not mention several others in an incipient stage. Two of the cases were in the last stage,—i.e. cavities had formed in the lungs; two others were bordering upon this stage. The remaining eight were in the second stage—that of softening; in five of these hæmoptysis was a prominent symptom. All these cases have done, or are doing, exceedingly well. Five of them have quite recovered; the others, with one exception, are in a fair way towards recovery.

"I have used it in many cases of whooping-cough and bronchitis, especially that form of the disease attended with laryngeal complication,—i.e. irritation of the superior laryngeal nerve, with a very harassing spasmodic cough; and in these cases I can speak of it as a remedy of the highest value.

"In dysentery and dysenteric diarrhoea, and in mucous diarrhoea with pain round the umbilicus, it is invaluable; one dose, or at most two, being sufficient. In simple diarrhoea it is hardly worth while giving it a trial. But its effects are most marked in cases of hæmorrhage, which it will arrest almost instantaneously; I have had several proofs of this. In some forms of neuralgia it also affords relief in a very short period.

"I hope I have now said enough to induce you to give it a trial. But don't be misled; it is not a *cure-all*, nor did I ever 'puff it off as a universal panacea for all ailments.' It is what is perhaps better—a valuable therapeutic agent, with which you may successfully combat disease in many of its forms, and those forms most frequent and most formidable. In addition to its astringent and anodyne properties, it also possesses remarkable chemical ones, and has a marvellous effect upon the absorbent and nutritive functions. I have seen cases of secondary sores and indolent ulcers assume quite new features, when the ordinary remedies have been combined with small doses of Chlorodyne."

From W. VESALIUS PETTIGREW, M.D. Hon. F.R.C.S. Eng., formerly Lecturer upon Anatomy and Physiology at St. George's School of Medicine.

"I have no hesitation in stating, after a fair trial of Chlorodyne, that I have never met with any medicine so efficacious as an anti-spasmodic and sedative. I have used it in consumption, asthma, diarrhoea, and other diseases, and am most perfectly satisfied with the results."

FROM THE "MEDICAL TIMES."

To the Editor of the "Medical Times and Gazette."

"Sir,—In reply to an inquiry made by your correspondent, who subscribes himself 'Nota Bene,' whether any cases of benefit from 'Chlorodyne' have come to the knowledge of your readers, I beg to say that I have been greatly pleased at the results in a case of severe pain in the hip-joint and in the vertebrae of the neck, which came on in a man long subject to chronic rheumatism, attended with permanent enlargement of the knees, ankles, and one of the wrists. He could not tolerate Opium, Hyosciamus, or Belladonna, and in despair almost I gave him a prescription for a mixture of Chlorodyne in water, the dose being twelve minims. He only took two doses, which acted so well that he compared his feelings to being transported to Paradise. The effects lasted for several days. Whenever his pains return, he now takes a dose at bedtime, feeling secure of an escape for some days from suffering. I have also applied it locally, with good results, but in too few cases to report much upon it. It produces a certain amount of warmth and perspiration, with a remarkably soothing state of mind, as well as arresting the pain. No headache or other unpleasant symptoms followed its administration.

"I am, etc. THOMAS A. HENDERSON, M.D. L.R.C.P., Physician to the Ramsgate Infirmary.

"The Vale, Ramsgate, September 23rd, 1857."

Extracts from the GENERAL BOARD OF HEALTH, London, as to its efficacy in Cholera.

"1st Stage, or Premonitory.—In this stage the remedy acts as a charm, one dose generally sufficient.

"2nd Stage, or that of Vomiting and Purging.—In this stage the remedy possesses great power, more than any other we are acquainted with, two or three doses being sufficient.

"3rd Stage, or Collapse.—In all cases restoring the pulse. So strongly are we convinced of the immense value of this remedy, that we cannot too forcibly urge the necessity of adopting it in all cases."

From Dr. ANDREW SMITH, Director-General, Army Medical Department.

"I have seen it used, and apparently with much advantage."

From F. E. BARTON, Esq., Surgeon, Dover.

"I have now used your Chlorodyne in numerous cases, and have much pleasure in adding my testimony to its very great efficacy as an Anti-spasmodic and Anodyne, having found it especially valuable in those cases in which opium does not agree well with the patient."

From JOHN E. GOULSTONE, M.D., Knighton.

"I can confidently state that Chlorodyne is an admirable Sedative and Anti-spasmodic, having used it in neuralgia, hysteria, asthma, and con-

Caution.—From H. W. BRIER, Esq., M.D. F.R.A.S., 18, George-street, Euston-square:—"I have found that coloured preparations of Chlorodyne have been nefariously substituted by several unprincipled Chemists, to whom some patients had sent their prescriptions to be prepared, thus causing alike disappointment to Patients and Physician." This statement of Dr. Brier is found to be too true, and much disappointment, and serious results have been occasioned thereby. The Profession are urgently and respectfully solicited to be very careful to whom their prescriptions are entrusted, or from whom a supply is obtained. Be sure to ask for Dr. J. Collis Browne's Chlorodyne. The genuine bears the manuscript signature of J. T. Davenport in red ink attested with his seal.

Sold to the Profession only, in 1-oz. and 2-oz. Bottles, at 3s. per Fluid Ounce.

Sole Manufacturer—J. T. DAVENPORT, Operative and Pharmaceutical Chemist, 33, GREAT RUSSELL-STREET, BLOOMSBURY-SQUARE, LONDON.

sumption with remarkably favourable results. It relieved a fit of asthma in four minutes, where the patient had suffered eleven years in a most distressing manner, no previous remedy having had so immediate and beneficial an effect."

From W. I. WALLISTENHOLME, Esq., Surgeon, Tottenham General Hospital.

"I can speak with much confidence to the good effects of Chlorodyne in harassing cough and consumption, affording relief when all other remedies had failed. I have seen it act with decided and immediate benefit in gout of the stomach, and in asthma; and I sincerely believe that all remedies, certainly within my experience, hitherto used as direct sedatives or diffusible stimulants, must yield to Chlorodyne."

From C. V. RIBOUR, Esq., M.R.C.S., Egham, Surrey.

"I am much pleased with your new remedy, Chlorodyne. As an Anti-spasmodic it is invaluable; as a Sedative, it is more certain and agreeable in its action than any I have hitherto used; and my experience of its curative effects in asthma, bronchitis, and neuralgia is most satisfactory."

From L. D. SMITH, M.D., Bingham, Notts.—July 29th, 1857.

"I am much pleased with the effect produced by your Chlorodyne upon the diseases to which I applied it. It seems to be far superior to any other Anti-spasmodic I ever used."

From CHARLES J. MASON, Esq., Surgeon, Surbiton, Surrey, July 27th, 1857.

"I have much pleasure in bearing testimony to the efficacy of Chlorodyne as an Anodyne and Sedative. I have used it in fever, colic, and rheumatism, with marked benefit."

From WILLIAM GALWAY, M.D., Mallow, Ireland.

"Dr. W. Galway begs to inform Mr. Davenport that he has found Chlorodyne most useful in neuralgia, and as an anodyne."

From Dr. THOMAS SANDFORD, Passage West, Cork.

"I will thank you to send me a further supply of Chlorodyne. It is the most efficacious remedy I ever used, affording relief in violent attacks of spasm within a minute after being taken. One patient in particular, who has suffered for years with periodical attacks of spasms of a most painful nature, and unable to obtain relief from other remedies, such as opium, etc., finds nothing so prompt and efficacious as Chlorodyne."

From Dr. B. J. BOULTON and Co., Horncastle—Sept. 28th.

"We have made pretty extensive use of Chlorodyne in our practice lately, and look upon it as an excellent, direct sedative and anti-spasmodic. It seems to allay pain and irritation in whatever organ, and from whatever cause."

"It induces a feeling of comfort and quietude not obtainable by any other remedy, and it seems to possess this great advantage over all other sedatives, that it leaves no unpleasant after effects."

From J. H. NANKIWELL, Esq., Surgeon, etc., St. Colombo, Cornwall.

"I have recently tried your Chlorodyne in a case of continued fever, as a diaphoretic; in a case of hysteria as an anti-spasmodic; and in a case of chronic laryngitis as a sedative; and from this short trial I am much gratified with its effects. I am disposed to think it a very important remedy."

From J. H. NANKIWELL, Esq., Surgeon, etc., St. Colombo, Cornwall. "I have found that coloured preparations of Chlorodyne have been nefariously substituted by several unprincipled Chemists, to whom some patients had sent their prescriptions to be prepared, thus causing alike disappointment to Patients and Physician." This statement of Dr. Brier is found to be too true, and much disappointment, and serious results have been occasioned thereby. The Profession are urgently and respectfully solicited to be very careful to whom their prescriptions are entrusted, or from whom a supply is obtained. Be sure to ask for Dr. J. Collis Browne's Chlorodyne. The genuine bears the manuscript signature of J. T. Davenport in red ink attested with his seal.

# The London and Provincial Medical PROTECTION SOCIETY, 43, Lincoln's-inn-fields, London. Conducted by a responsible Committee of Medical Men.

PRESIDENT.  
JOHN PROPERT, Esq.

TRUSTEES.

Nathaniel Clifton, Esq., Islington. G. Webster, Esq., M.D., Dulwich.  
J. Propert, Esq., New Cavendish-st. Horatio Day, Esq., Isleworth.

COMMITTEE.

John Harrison, Esq., Chester.

TREASURER—Robert Dunn, Esq.

BANKERS—Messrs. Gosling and Sharpe, 10, Fleet-street.

SECRETARY—John Capes, Esq.

The objects of the Society are—  
1st. To provide a safe and efficient medium by which the Medical Profession may secure more certain and regular payment for their services; with every consideration for the convenience of those who are willing, but unable directly to discharge their liabilities; with rigour from those who are able, but have not the disposition to remunerate medical men.

These ends to be accomplished without interfering with the valuable time of the Members of the Profession, or exposing them to the unpleasantness which necessarily attends applications for money, or to the uncertainty and risk of employing private collectors.

2nd. To assist members with information and advice in the purchase and sale of practices.

3rd. To raise a Benevolent Fund by devoting to that object the profits arising from the general operations of the Society.

The Society consists of qualified Medical Practitioners only. Annual Subscription, One Guinea; a Firm, consisting of Two Partners, a Guinea and a-half; a Firm of three Partners, Two Guineas. Fixed rates of Commission are also charged on Business transacted.

The general business is carried on by a staff of officers at the Central Office, 43, Lincoln's-inn-fields, together with trustworthy employees appointed in town and country, the whole of whom are under the direction and superintendence of the Committee.

The Metropolitan Members of the Committee, with the Trustees, are responsible for all moneys received by the Staff.

## Carriages, New and Second-hand, of

superior style, sterling quality, and finest finish at reasonable rates, or cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.

OFFORD'S PATENT MEDICAL-MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.

## Wines from South Africa.—Port,

SHERRY, etc., TWENTY SHILLINGS PER DOZEN. These Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome, and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices. A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy, and the opinion formed is that they are worthy of being patronized."—Clerical Journal, October 23, 1857.

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen. Terms—Cash. Country orders must contain a remittance. Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

## Russell's

ELASTIC TRUSS.

Described in this Journal, March 6 (page 247). Invented and made by WM. RUSSELL, 184, Orchard-street, Portman-square, W., who earnestly solicits the Profession to put it to the test by having it applied to cases where the Steel Spring Trusses have failed, either through the patient being unable to bear the annoyance they

occasioned or otherwise. As also in the cases of infants and children, as in such cases they have proved a great boon. Any gentleman wishing to test it may do so by sending a poor patient, who shall have one fitted gratuitously.

Russell's Improved Zwanke's Pessary, Spiral Elastic Bandages, etc.

## Horniman's Pure Tea, the leaf

not coloured.—Rich full-flavoured TEA of great strength is thus obtained, as importing it not covered with powdered colour prevents the Chinese passing off the low-priced brown autumn leaves as the best. The "Lancet" (Lancet, p. 318) states of Horniman's tea:—"The Green not being covered with Prussian blue, etc., is a dull olive; the Black is not intensely dark." Wholesome and good TEA is thus secured. Prices 3s. 8d., 4s., and 4s. 4d. per lb. London agents:—Purcell, 78, Cornhill; Elphinstone, 227, Regent-street; 266, Oxford-street, and 21, Throgmorton-street, Bank; Wolf, 75, St. Paul's-churchyard; Dodson, 98, Blackman-street, Borough. Sold in Packets by Horniman's Agents in all parts of the kingdom.

## Williams and Son's Pure Glycerine

SOAP. Analyzed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.  
THE MEDICAL TIMES AND GAZETTE.  
THE BRITISH MEDICAL JOURNAL.  
THE MEDICAL CIRCULAR.  
EDINBURGH MEDICAL JOURNAL.  
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, etc.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

TO SURGEONS, APOTHECARIES, AND DRUGGISTS.

## Important Saving, by Prepayment,

in the PURCHASE of NEW WHITE ROUND MOULDED VIALS OF THE BEST QUALITY. FELLATT and Co. submit the following PRICES of VIALS, for PREPAYMENT only:—

	per Gross, 6s.	In quantities of not less than
1 oz., 10 dr., and 11 oz.	7s.	Six Gross, assorted to suit the convenience of the purchaser, delivered to carriers in London.
14 dr., and 2 oz.	8s.	No charge for Package.
3 oz.	10s.	Breakage at risk of Purchaser.
4 oz.	12s.	
6 oz.	14s.	
8 oz.	16s.	
12 oz.	18s.	
4 1/2 oz. graduated in 3 doses,	12s. 6d.	chaser.

The above Prices being based upon a calculation which excludes all charges whatever between the Manufacturer and the Consumer, no attention can be paid to any order not accompanied by a remittance in full, made payable in London.—F. and Co. do not supply Green Glass.—Orders and remittances to be addressed.

FELLATT & Co.,  
FALCON GLASS WORKS, LONDON.

Or SACCHARATED CAPSULES, approved of by the French College of Physicians, successfully administered in the Paris and London Hospitals, and acknowledged by them to be the best remedy for the cure of certain diseases. (See the "Lancet" of 6th November, 1852; "Medical Times" 10th December, 1852; a copy of which will be forwarded on application.) Price per 100, 4s. 6d.; 50, 2s. 9d.

To be had of the Inventor, GABRIEL JOZEAU, sole French Chemist, 49, Haymarket, London, whose name is printed on the Government stamp, and of all the principal Chemists of England.

BROUGHAMS.

## Kinder, McNaught, and Smith,

MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in.	7 1/2 cwt.	85 Guineas.
3 ft. 6 in.	8 1/2 cwt.	95 Guineas.
3 ft. 7 in.	9 cwt.	100 Guineas.

The latter, including a segmental front, with seat for third person. These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

PURE SPIRITS FOR THE FACULTY.

## S. V. R. 56 o.p., 16s. 6d. net Cash.

This quotation admits of neither credit nor discount, and is per gallon must be added for packages, to be allowed on their return. HENRY BRETT and CO., Old Farnival's Distillery, Holborn.

## Wines from the Cape of Good Hope.—

PORT, SHERRY, MARSALA, MADEIRA, DUCELLAS, &c., all at 20s. per Dozen—pure and wholesome Wines, free from acidity and brandy, the produce of vineyards at the Cape of Good Hope, where the vines of Portugal and Spain are now being carefully cultivated, and have escaped the disease. Her Majesty's Government allows these Wines to be imported at half the duty, hence the low price of 20s. per dozen. Samples of any two qualities sent on receipt of twelve stamps.

The UNIVERSAL BRANDY, 15s. per Gallon, or 30s. per dozen. "That wine, equal to any ever produced, can be made at the Cape, all the world has acknowledged."—Times, Nov. 8th, 1855.

W. and A. GILBEY, Wine Importers, Brandy Distillers, &c., 57, Oxford-street, London, W.; three doors west of the Pantheon. Cheques to be crossed to our Bankers, the Bank of England.

Consulting Physician to the Bristol General Hospital, &c.

## ON HEADACHE.

## LECT. I.

**DIFFICULTIES** of the subject.—A subjective phenomenon.—The part affected not open to physical exploration.—Similarity of symptoms from different pathological conditions.—Ambiguity of evidence from remedies.—Seat of pain.—How the topography of the body is learned by consciousness.—The vagueness of the information derived from consciousness as to the source of pain.—Sympathetic pain by radiation, and by transference.—What nerves are the seat of pain in headache.—Ganglionic mingled with fibres from some of the cranial nerves.—The agencies by which these nerves are made to ache.—Local and remote.—How remote irritations induce headache.—Inquiry into the mode in which morbid impressions are transferred.—The internuncial function of the sympathetic nerves in morbid changes.—Examples of transferred irritation.—Sympathy between the tegumentary surface and internal organs probably maintained by ganglionic nerves accompanying the blood vessels.—When the irritation is intracranial, difficulty of distinguishing purely nervous pain from that which is dependent on vascular disorder.—Peculiarities of intracranial circulation.—Experiments as to the distribution of the cerebro-spinal fluid in altered positions.—Fatal effects of position in diminishing the amount of blood in the brain.—Is the cerebro-spinal fluid vital or cadaveric?

It seems to me that I should be scarcely manifesting the proper degree of respect for the Royal College of Physicians, and I should certainly be doing violence to my feelings, were I to commence the duty before me without premising one word in grateful acknowledgment of the honour conferred upon me in the appointment to this lectureship, and without expressing my earnest hope that my short-comings may bring no great discredit on the office. To think of my predecessors is enough to overwhelm me with a sense of my unworthiness to follow in their steps, and it is certainly trying to my self-reliance, to know that my *rusticus sermo* will be uttered within walls which have echoed the eloquent wisdom of so many of the great departed, as well as of the illustrious living, and that I am addressing the highest council of my Profession. But it is too late to hint at fear or self-mistrust. Whatever may be the seriousness of the task which I have undertaken, I have undertaken it; and I must do my best to go through with it, being assured that I shall receive as much tolerant attention, and as much clemency of criticism as may, with any reason, be claimed by those who presume to occupy posts and engage in duties which they were quite free to have declined had they been conscious of their incapacity.

The subject which I have selected, is one that has been acknowledged by all thoughtful practitioners to be attended with considerable difficulty—difficulty as to the pathology and diagnosis of headache, and corresponding difficulty as to the remedies which it requires.

Dr. Willis in the second part of his *Pathologia* prefaces what he has to say of headache with these words:—

“*Cephalalgia, etsi creberrimus affectus, originem tam variam, incertam, et non raro contrariam, habet, ut difficillimum videatur exactam ejus theoriam, φαινομενον tam multiplicitum et sæpe oppositorum solutiones continentem, tradere. Morbus hic nulli temperamento, constitutioni, victus rationi, nulli causarum evidentium aut continentium generi constans, frigidos et calidos, sobrios et imtemperatos, juvenes et ventre plenos, pingues et macilentos, juvenes et senes, immo quolibet cujusque ætatis, sortis, et conditionis, homines passim incescit. Hinc, siquidem ægroto cuiquam hujus rationes sciicantibus alias satisfieri nequeat, sæpissimè dicisoleat, omnia ex vaporibus procedere.*”

There is a treatise by Juncker of which I only know the title, which runs thus: “*De Doloribus Capitis; scandalo medicorum, difficulter removendo.*”

One of the most learned of our contemporaries, Dr. Copland, says:—“There is no disorder which tries the science, experience, powers of observation, and acumen of the physician more than this does, and there is none that requires a more precise estimate of the pathological conditions on which it depends, as a basis for safe and successful indications of cure.”

VOL. XXXVII No. 964. NEW SERIES, No. 403.

I am not so weak and presumptuous as to suppose myself capable of dissipating the obscurity of the subject. My aim is only to throw upon it whatever little light I may have been able to gather from my own observation and reflection, as well as from the labours of other inquirers.

The very frequency of the complaint is an excuse for recurring to the study of it. For surely the head is more given to aching than any other part of the body. Put all the breast-pains, stomach-pains and colic pains together, and you do not make such an aggregate of suffering as is furnished by headache; the *dolor dorsi* of the female comes near it. Toothache alone can compete with it, but it has generally some local disorganization to account for it; and were there a like proportion of structural disease answerable for headache, there would soon be an end to the wits, and indeed the life of half Christendom. Barbarism would once more be in the ascendant for a time, though civilization and headache would again overtake it.

One of the first difficulties is that the principal phenomenon is not an objective fact, but a form of consciousness described to us by another. And the region of the body to which the sensation is referred is one which, from its anatomical construction, prevents us from comparing the patient's feelings with information derived from such direct physical examination as enables us by manipulation in abdominal diseases, and by auscultation in those of the thorax, to verify or correct the declarations of the sufferer. The most important part of the head presents a bony barrier impervious to touch, and impenetrable to sight and hearing. To assay the value of the patient's complaints and descriptions, we are compelled to weigh with them or against them, as the case may be, a multitude of facts which relate to the presumed functions of the parts contained within the cranium, as well as to all the other functions of the economy. For a patient to localise pain correctly, even in the best known parts of the body, is often very difficult, and still more so where the head is apparently the seat of pain, the greater part of that region being to him absolutely a *terra incognita*.

Another difficulty which very early presents itself is to ascertain whether the pain, supposed to be in the head, has its origin in that part, or whether it be not merely a reflected sensation, a doleful echo of suffering in some other organ. There are difficulties also offered by the perplexing nature of some of the very knowledge to which we have attained. For instance, we know that the brain when subject to the influence of an increased or lessened amount of blood, presents symptoms closely similar. Delirium, insomnia, and coma, may ensue alike on a hyperæmic or an anæmic state of the brain.

And again, the agencies which remove or relieve headache give very ambiguous evidence. Thus it might seem at first sight that a headache relieved by food must depend on exhaustion. Yet it is quite conceivable that the headache, if dependent on a congestive state of brain, might be relieved for the time by the greater afflux of blood to the stomach in the first processes of digestion; just as the cough of subacute bronchitis is often temporarily relieved by an analogous derivation at the time of a meal, and for a short time afterwards. A stimulant, again, especially if it be very pungent, acts as a rubefacient to the gastric membrane, and thus revulsively takes off the stress from the cerebral vessels for a brief time, though the alcohol received into the circulation will in a few hours increase the evil. The beneficial effect of purgatives is often hastily presumed to prove that the cause of the headache is in the liver or bowels, when it may really import that the circulation of the brain has been lightened. In like manner the constipation attendant on such cases may be less the cause of the headache than the effect of the intestinal torpor consequent on cerebral oppression.

In many instances the complication of morbid agencies gives a considerable intricacy to the diagnosis. Let the patient be of an unacknowledged gouty habit—his headache may be caused by the gouty poison in the blood, or by the general plethora, or by the gastric or duodenal dyspepsia, or by the faults of the hepatic function, or by intestinal inaction, or by the irritability of the nervous system, to some one or all of which disorders gouty patients are proverbially subject.

The pain of headache is, of course, in some of the nerves of the head; but over what tissue are the aching nerves distributed? The mere consciousness of the most accomplished

anatomist suffering this affection (*i.e.* his consciousness unaided by clinical experience), will afford scarcely any discriminative information. A neuralgic or rheumatic affection of the scalp, a pain from pericranial inflammation, or inflammation of the frontal sinus,—these may be distinguished, perhaps, by the mere feeling in the part. And obviously a sufferer may have learned to locate his pain with great accuracy, but it will have been by means of inference, and experience of *juvantia* and *ludentia*. The difficulty is greatest in the common headache, that torment to the individual and pest of society, which so often interrupts the daily occupation, spoils the arrangements of social life, and drives the sufferer to the domestic medicine chest, and thence to the family practitioner and the medical celebrities of the day; while but too often, from their baffled science and art, the patient flies frantic with disappointment to a series of quackeries, ending in greater disappointment, because beginning with more extravagant expectation.

It will, I think, be a fitting commencement of our inquiry into this subject to consider the mode in which we become acquainted with the locality of pain in general.

What is pain? would seem at first sight to be one of the most superfluous of questions, seeing that pleasure and pain are the simplest, least decomposable states into which consciousness can be resolved. But though pain is used in the abstract as expressing in shortest phrase the suffering of the *ego*, it seldom is presented to our notice without the association of some locality of the body. So much is this the case, that if a person complains of pain, we inquire immediately for its seat. Suffering, or a painful condition of the *ego*, may be quite independent of bodily feelings. In sorrow, mortification, and remorse, there is not necessarily any reference whatever to the body; but pain belongs to the body, and is attributed only by a metaphor to the mind.

The assignment of the seat of pain might seem, at first, to require only an appeal to the consciousness; but the inquiry, Where is the pain? receives not unfrequently the vaguest and most erroneous of answers, and sometimes none at all. But supposing the answer to be tolerably correct, let us endeavour to analyse the process by which the pain is referred to some determinate part of the body. Preliminary to this inquiry is another, How do we become acquainted with the topography of our bodies? It is undeniable that, to an enormous majority of mankind, a very large portion of their frames is utterly unknown. They know less of their bodies than even what a person who has never studied geology knows of the structure of the earth. But we will not take into account such knowledge as the anatomist acquires, but only such as those are possessed of who speak of their bodies and their members.

There must have been a time in our existence when our bodies formed a part of the external world, which had to be learned by a gradual process of experience, analogous to that which subsequently made us acquainted with the position, distance, form, and properties of objects external to our bodies.

If you watch a very young infant you can detect no indication that anything is present to its consciousness, but the bodily comfort or discomfort of the moment—hunger or satisfaction of the stomach—warmth or cold; perhaps there may be a faint perception of light and sound; but the strongest recognition of the *non-ego* is in those fibres of the fifth pair which are impressed by the nipple. It is highly probable that the muscular sense gives various impressions to the infant, but they are not as yet so connected with other sensations as to impart the knowledge of body and limbs. This knowledge, indeed, must be the result of the slow accumulation of coherent sensations, such as the sight of the parts in question associated with the tactile sensations excited by the presence or the pressure of that on which the body rests, or of an applied or adjacent limb, as a hand or foot, and with the various muscular sensations incident to the movements of the limbs. The knowledge of some of the superficial parts of the body must be the result of inference or analogy. The shape of the back of the head, and of the trunk, being out of the range of vision, can only be known by the analogy of other human beings. When the parts of the body have been learned and appropriated to the unity of personal existence, a recognition which grows by degrees like the rest of this department of knowledge, and in conjunction with it, the individual is still far from such proficiency as would enable him

to answer that apparently simple question, Where is your pain?

It is often in vain that you ask a child, otherwise quick enough in answering questions, whereabouts he is suffering; and even adults, though indicating a region of the body, seem perplexed in their attempts to define with more exactness. Some automatic actions of children appear at first sight to indicate a knowledge of the seat of pain, as when the hand is carried towards the head in meningitis. But such actions are to be observed in profound sleep and in coma, and in all probability they belong to the class which have their analogues in almost the lowest divisions of animal life, and may be seen in some animals after decapitation.

I think, then, that we may assume that the conscious reference of common sensation to any particular part of the body must be the result of experience, whether it be correct or erroneous in its teaching; the experience itself consisting, as we have already hinted, in the accumulation of associated perceptions. The more frequent in occurrence, and the more diverse these have been, the more accurate will be the reference; as when tact and touch, and muscular sensation, and sight, all contribute their several items. The precision will also be proportionate to the nervous endowment of the part in question, seeing that tactile sensation itself is well defined or confused, according to the more or less liberal distribution of primitive nervous fibres.

However discriminative the sensibility of the skin may be, it is obvious that different impressions are perpetually sent from every portion of the cutaneous surface, whether from the contact of dress or from the collision of outward objects, or from changes of temperature, as well as from muscular movements,—and that by means of these, as well as by sight and analogy, the topography of the surface is well learned, so that when a new impression occurs in any part, the feelings of the part with which it is associated at once denote the locality of the impression.

But while this is the case with the skin, it is far otherwise with those parts of the body which are not so continually telegraphing the sensorium. Take the mucous surface which comes next to the skin and special organs of sense, in relation to the outer world. In the healthy condition of the digestive membrane no sensation is caused by the food from the time it leaves the gustatory part of the apparatus till its final expulsion, notwithstanding all the wonderful changes it undergoes, mechanically and chemically, as well as the immense variety of secretions which it causes to be poured out on the several portions of the surface which it traverses. The membrane seems equally insensible to the variations in the temperature of the solids and liquids applied to it. A man in health may therefore attain to extreme old age, and by reason of his health, and consequent unconsciousness of internal organs, be as ignorant as an infant of the topography of that tube by which he has received his life and strength. A like remark might be made as to the bronchial and other mucous surfaces; and if it be true of the mucous tissue, it is still more so of those which lie still farther removed from the external world, whether as serous linings or as textures composing the parenchyma of viscera, or the fabric of muscles, bones, etc.

Now though all these parts may be most accurately known by the anatomist, and though he may therefore apply the knowledge analogically to his own person, yet it will be very difficult for him to localise a new sensation, such as pain, by mere reference to his simple consciousness, without experience and inference; for mere consciousness will not distinguish mucous membrane from cellular, nor this again from serous. He will arrive at any correct localisation only by a series of experiments and inferences. Some of these consist of observations on the effects of change of posture, or of the relative movements of other parts of the body, or on pressure with the hand, and on the influence of the outer air, or of the contact of foreign bodies, or of food or drink. But others are of a purely medical nature, and depend on previous knowledge of the functions of the parts, the products by secretion, etc. Were he the subject of subacute peritonitis he would need the information of pressure, and of the action of the abdominal muscles. And to say whether a pain in his side were pleurisy or intercostal rheumatism would require all his clinical knowledge.

These difficulties, then, which we meet with when referring to consciousness as distinguished from inference, for infor-

mation as to the seat of pain in general, have peculiar force when we appeal to it for the source of pain in Headache. The patient may entertain a dim idea that it is internal; or the tenderness of the scalp may make him think it external, but as to anything like exact information as to the parts which lie within the cranium, it would be absurd to look for it as the result of consciousness.

We have already hinted that these impediments to our knowledge of the source and seat of pain are enhanced by the fact that pain is easily diffused beyond its original source, or transferred in what we call sympathy. There is an obvious distinction to be drawn between the radiation of painful sensation, and the transference of sensation from one part to another. In the former case pain simply extends circumferentially beyond the part which is impressed by the disturbing agent. Physiologists are agreed that impressions are not communicated from one nerve to another in the way of anastomosis, but that the impressions travel separately along each individual primitive fibre to the sensorial centre.

Now though nerves do not communicate in their course, a hundred facts show that there is a most prompt and intimate connexion between the related vesicles of the central parts in which they terminate. It is by such a communication that that association of sense and ideas takes place which refers the new sensation to a particular part of the body. Say that a wasp has stung the dorsum of the foot. The nervous fibre on which the painful impression has been made, is so related at its central extremity with the nerves, whose several communications have by frequent association or coherence formed that complex idea, that bundle of recorded sensations which we label *dorsum pedis*, that the pain is at once referred to this part, and for a short time there may be nothing present to the consciousness but the point of pain, and the idea of the foot. But in an irritable habit the pain may soon extend to the whole foot, or even the whole limb, without any corresponding extension of the local irritation caused by the wasp poison. The fault is not in the periphery but in the centre. That condition of the central part in which pain consists is communicated to other like central parts, and their pain is by the law of their being referred to their several peripheries. In different subjects there is a vast difference in the readiness with which these communications are made. Persons are called irritable, nervous, susceptible, hysterical, when the proclivities to such communication is very marked. Such persons may also feel pains which have taken their origin from mere ideas. A bodily pain is described, and the idea of the pain is so vivid, and so readily yoked with the idea of the part, that it seems to be projected into that part, being, however, a purely spectral pain—just as a visual conception may be so vivified as to produce the same effect and conviction of reality as if it were a direct outward perception.

It is not uncommon for a person to be able to produce a sensation of cold through the frame by merely recalling some disagreeable sound or feeling of touch, which has elicited such sensation of cold. I know a person who is so distressed by the touch of woolly substances, especially coarse green baize, that when the mere idea of such a substance is recalled to his mind, he suffers a sort of horripilation. I also know an individual who is particularly liable to a kind of vertigo on ascending a ladder, and who can not only bring on the feeling by imagining to himself some giddy height, but who also actually feels when under the influence of the same idea a sensation of pain in the soles of the feet. There is an obvious physiological relation between the plantar nerves and the feeling of equilibrium; but that the mere idea of a vertiginous situation should cause actual pain in these nerves which are only inferentially known to be connected with equilibration, seems to me to be a curious and interesting fact.

There are certain well-known sympathetic pains which do not come within the scope of the law of radiation or diffusion. Such are the pain of the shoulder in hepatic disease, but which in my experience has been oftener related with diaphragmatic pleurisy, the pain of the knee in disease of the hip-joint, the pain along the genito-crural nerve from calculus in the kidney or ureter, the pain over the eye from ice applied to the interior of the stomach, and itching of the nose from ascarides in the rectum.

In these instances the impression is conveyed along certain nerves, reaches their centre, and without awakening a sensation in it, passes on to the vesicular termination of some other

nerve either near or remote. When the origins of the nerves are so near as that of the phrenic and that of the nerves of the shoulder, the communication between their centres does not seem so difficult to understand, though why the impression should be transferred instead of being participated, is still obscure. With more distant nerves, as those of the stomach, even allowing the gastric branches of the vagus to be the afferent nerves in this case, it is not easy to see the mode of communication and metastasis between the origin of this nerve in the medulla oblongata, and the origin of the ophthalmic branch of the trigeminus. One thing I think worthy of notice is, that the metastasis is usually from a less to a more sensitive nerve. In the normal state the shoulder is oftener productive of sensation than the diaphragm or liver, the genito-crural nerve than the renal, and perhaps the knee than the hip; and certainly the nerves of the fifth pair than those of the stomach. When a mistake has been made, one can conceive that if two nervous centres are the seats of an impression, the consciousness may, by habit, refer it to that one, and its corresponding nerves, with which it has been oftener brought into relation. I need not say that the mistake is by no means the rule, the sensation being often referred to its real source; and that when the impression is a very strong one, both parts may partake of it. Thus we have known in a violent diaphragmatic pleurisy the pain in the side attended with equally severe pain in the shoulder and the neck, to such a degree as, together with the absence of auscultatory signs, to have induced the erroneous belief that the case was one of rheumatism.

We shall have to return to this sympathetic translation of feeling when tracing the causes of headaches. In the meantime it may be remarked, that to the student of final causes some of these morbid sympathetic sensations are all but insuperable difficulties. What warning does that supra-orbital neuralgia give against the ingestion of ice? How seriously have the comfort of patients and the reputation of surgeons been affected by that misplaced pain of the knee! It may be that the general good of the economy may have required that the centres of certain nerves should be so related to each other, and to the nerves which originate the knowledge of localities in the body, that nevertheless in morbid states they may present this false information; but, so far as the sympathetic pain is concerned, it seems, like so much of pain in general, to be an unquestionable evil. Pain may often be curative or prophylactic, as if St. Michael had compelled it to be so; but not unfrequently it seems to be the true friend and servant of Lucifer. Perhaps a more philosophical rationale would be, that made on a certain plan conformable to the general laws of organization, in which decay and death are contemplated no less than genesis and preservation, the organism has pain for one of its destructive elements.

Putting aside for the present any reference to the patient's feelings, what do we learn from anatomical considerations as to the probable source of pain within the cranium when a person is the subject of headache? It does not appear to be in the nervous matter, whether vesicular or tubular, of the cerebral hemispheres or of the cerebellum. No evidence of feeling has been obtained by vivisections till they approached the sensory ganglia—the thalami optici and corpora quadrigemina. But these are the centres of sensation to all parts of the body, as well as to the head. All analogy must further look for nerves as the source of the pain (though some writers are hardy enough to doubt the necessity of nervous matter as instrumental in sensation). And what are the nerves? Numerous as are the nerves which come out of the cranium, there are to a superficial view very few that go into it. A branch of the sub-occipital accompanies the vertebral artery; but a large majority of the other nerves, destined for intracranial purposes, are derived from the sympathetic. These, then, are the nerves which are of the chief interest to our present inquiry. Nerves of this class accompany blood-vessels; and when we observe the large amount of these vessels, the brain and its membranes being more liberally supplied with blood than any other organ, the quantity being computed as one-fifth of the blood of the whole body, we might, without searching further, feel convinced that there must be a correspondent supply of ganglionic nerves. But the minute examination of modern anatomists has tracked them in great abundance.

If we may trust the delineation in the plate representing the cephalic termination of the Great Sympathetic, in the magnificent work of MM. Bourguery and Jacob, which plate embodies

the results of the dissection on which was founded the memoir presented by M. Bourguery to the Academy of Medicine, there is a vast interlacement of nerves at the base of the brain, derived from the plexuses of the vertebral, the basilar, and carotid arteries, mingled with threads communicating with the third, fourth, fifth, and sixth pairs of cranial nerves, besides branches in the cavernous plexus derived from some of the upper cervical nerves, as well as those connected with the pituitary body otherwise called the cephalic ganglion. The nerves proceeding from this network and accompanying the arteries of the brain must possess the mixed endowment of the several sources. But whether or not the sensory properties of ganglionic nerves are entirely dependent on the cerebro-spinal fibres contained in them, as Valentin believes, or whether they arise from the grey fibres which become sensitive when altered by disease, as Volkman supposes, these are questions which it would be irrelevant to discuss on the present occasion.

It is enough for us that the composite nerves of this class seem to fulfil almost every conceivable function of a nerve. Whatever they may effect on the chemical processes in the molecular laboratory of ultimate tissue; whatever regulation they give to the blood-vessels, it can scarcely be doubted that in many parts of the body they send messages of pain, if not of pleasure, to the sensorium, and that they transmit influences from the seat of emotion to the parts where they are distributed, and it is not proved that they do not possess a kind of reflex function. They only seem not to attempt to convey motor impulses from the will. That our general sense of well-being must derive its favourable tidings from the viscera through these nerves can hardly be doubted; but certainly there is no other channel through which flow the miseries and anguish of ordinary visceral disorders.

Admitting, then, that the ganglionic nerves distributed through the brain and its membranes are implicated in painful affections of the organ, our next inquiry would be turned to the agencies which so act upon them as to cause painful feeling. Some of these are obviously local changes in the cerebral structure from organic disease, inflammation, and injuries. There are also changes in the blood, as in the headache of fever. But there are also disordered states of the nerves themselves resulting from functional causes, as in excessive mental exertion and emotional excitement. Other causes again act by sympathy; through the nerves of special sensation for instance, as when vivid light and loud noises excite headache. There are also very familiar examples of pain in the head, occasioned by impressions on branches of the fifth pair, as well as on gastric and intestinal nerves.

(To be continued.)

## LECTURE

ON

## PIROGOFF'S AMPUTATION AT THE ANKLE-JOINT,

DELIVERED AT THE

Crossbencher-Place School of Medicine,

MARCH 5, 1868,

By T. SPENCER WELLS, F.R.C.S.

Lecturer on Surgery at the School; Surgeon to the Samaritan Hospital, &c.

GENTLEMEN,—At our last meeting we practised various partial amputations of the foot. On one side of the subject before us we will now practise Syme's amputation at the ankle-joint, and on the other side an operation coming into fashion here, devised by the celebrated Russian surgeon, Pirogoff, who was chief surgeon in Sebastopol during the greater part of the siege. I have brought his own description and the drawings he has published of his operation with me, that we may follow his directions exactly; for I have seen what has been called his operation performed in a very different manner, and with very different results to those he describes.

I will now translate to you his own words, and, having his drawings before us, we will follow carefully the various steps of the operation as he directs. He says:—

"I commence my incision close in front of the outer malleolus, carry it vertically downward to the sole of the foot, then transversely across the sole, and lastly obliquely upwards to the inner malleolus, where I terminate it a couple

of lines anterior to the malleolus. Thus all the soft parts are divided at once quite down to the os calcis."

Here is the diagram. The inner extremity of this incision

is carried obliquely forward some lines anterior to that on the outer side, in order not to cut through the posterior tibial artery until after its division into the plantar branches. Now let us make this first incision and proceed.

"I now connect the outer and inner extremity of this first incision by a second semilunar incision, the convexity of which looks forward, carried a few lines anterior to the tibio-tarsal articulation. I cut through all the soft parts at once down to the bones, and then proceed to open the joint from the front, cutting through the lateral ligaments, and thus exarticulate the head of the astragalus."

You see I have made this second incision, have opened the joint, and using only the point of the knife upon the strong ligaments which keep the astragalus in its place, have completed this part of the operation with the greatest facility. The joint is found very readily by fixing the malleoli, and alternately flexing and extending the foot. It is opened with the greatest ease by holding the foot strongly extended, and as the capsule is very broad, the joint opens at once. The internal lateral ligaments are easily divided. The only difficulty in disarticulating the astragalus is about the outer malleolus, but it is easily overcome by cutting closely with the point of the knife all round the malleolus, so as to divide the ligaments which pass from it. Keeping up the extension of the foot the head of the astragalus starts out, and then "it is only necessary to cut through the posterior wall of the capsule to expose the sustentaculum tali." Now for the third step:

"I now place a small narrow amputation saw obliquely upon the os calcis behind the astragalus, exactly upon the sustentaculum tali, and saw through the os calcis, so that the saw passes into the first incision through the soft parts."

Just look at the skeleton: see how the os calcis is grooved on its internal surface. Here about the middle of this surface is the process—sustentaculum tali—supporting the anterior part of the astragalus. I now follow Pirogoff's directions. The saw I use I should have called "Butcher's" a week ago, but it is one just sent me by Mr. Hilliard, an instrument-maker of Glasgow, who says it was given many years ago to Dr. Laurie by Dr. Grahame. You may call it Grahame's saw or Butcher's saw, as you please. It answers our

present purpose admirably by either name, though not better than one of the narrow resection saws of Langenbeck you have seen me use so often.

Pirogoff says very truly,—"Saw carefully, or the anterior surface of the tendo achillis, which is only covered by a layer of fat and a thin fibrous sheath, might be injured."

You see a very few strokes serve to cut through the os calcis, and a touch or two of the knife upon a few shreds left undivided in the sole close to the bone separates the foot. So

far the proceeding is a very rapid one. I would be bound to do it easily without the least hurry within one minute.

This sawing the os calcis may be called the third step of the operation; now for the fourth. Lastly, says Pirogoff:—"I separate the short anterior flap from the two malleoli, and saw through them at the same time close to their base."

Well, this is done without the least difficulty; and now you see the great difference between this operation and Syme's. I say nothing now of the much greater ease and rapidity with which it is done; but you see at a glance that the posterior flap is not a hollow, it forms nothing like a cap or bag, but it contains the posterior tuberosity of the os calcis with the insertion of the tendo achillis. This diagram represents the appearance very well.

"I turn this flap forwards, and bring the ~~cut~~ surface of the os calcis in apposition with the articular surface of the tibia. If the latter be diseased it is sometimes necessary also to saw off from it a thin slice with the malleoli." In the drawing the articular surface is shown, though not so accurately as in the original, the artist not having exactly caught the line of demarcation between the cut bone and the cartilage.

Now let us see what advantages Pirogoff claims for his method. He says:

"1. The tendo achillis is not divided, and so we avoid all the disadvantages connected with its injury.

"2. It also follows that the base of the posterior flap is not thinner than its apex, while the skin on the base of the flap remains united with the fibrous sheath of the tendo achillis.

"3. The posterior flap is not cap-like, as in Syme's method, and its form is therefore less favourable to a collection of pus.

"4. The leg after my operation appears an inch and a half (sometimes even

more) longer than in the three other operations, (Syme, Baudens, Roux,) because the remnant of the os calcis left in the flap, as it unites with the inferior extremities of the tibia and fibula, lengthens them by an inch and a half, and

"5. Serves the patient as the point of support."

But to return to the case before us. I will use three or four sutures to keep the flaps together, and now see how beauti-

fully they fit. Look at the stump from the side. Look at it from behind. It is really admirable, and by bringing the feet together you may see that this diagram is quite correct, and that the difference in length of the two feet when the pelvis is placed square is not more than from an inch and a quarter to an inch and a half.

After operating on the living subject, Pirogoff leaves the two angles of the wound quite open, to admit of free discharge.

In reply to the objection that the remnant of os calcis left in the flap might die, and act as a foreign body, he says the fear that this might prove to be the case prevented him from adopting the operation on the living subject long after trials on the dead had shown its advantages. He also feared that this remnant of os calcis, even if it did not die, would still not adhere to the surface of the tibia, and consequently would become useless as a point of support. But after reflecting upon the facts, that the periosteum of the tuberosity of the os calcis is very closely united both with the skin and with the fibrous sheath of the tendo achillis, and is very plentifully supplied with vessels by the *rete calcanei*, he resolved to try the operation on the living, especially as cases occurred which taught him that in wounds of the head by sabre strokes, flaps containing considerable segments of the cranium reunited with the bone below, both by first and second intention. Up to April 1853 he had performed the operation in three cases, the ages being 12, 13, and 19. All these recovered well, and two of them walked well without stick or crutch, and without limping or tottering. These cases proved undeniably that the tuberosity of the os calcis left on the flap does unite with the tibia, and adds so much to the length of the stump that it nearly reaches the level of the sole on the sound side; secondly, that the tendo achillis is not stretched by the altered portion of the tuberosity; and thirdly, that the progress and healing of the wound need no special attention not required after the other amputations at the ankle. Collections of pus in the sheaths of the divided tendons are observed after any of these amputations. Pirogoff proposes that graduated compresses should be used, and fixed with the immovable plaster of Paris bandage in the course of the tendons on either side of the leg. He believes also that the tendons should not be cut off too short, in other words, "not too near the spot where their synovial sheaths are cut through; their ends should rather project a little. If they are cut too short they conceal themselves in the fibrous canal, or what is worse, when the limb is moved they slip upwards out of their sheaths." He adds:—"I fear nothing so much as this, namely, when the belly of the muscle contracts, and draws up the tendon divided, or half destroyed by suppuration, out of the sheath. I am convinced that the fixing of the

tendons before and during the operation by methodical pressure, and the continuous maintenance of the limb in one and the same position by the plaster bandage may contribute a great deal towards the successful result of these operations."

I will also read you his concluding observations, as they have a very important bearing upon the selection of cases for the operation. They are as follows:—

"It was also worthy of remark that in one of these cases, notwithstanding the suppuration and the considerable gravitation of pus into the flap (in the third case); notwithstanding the softness and fatty degeneration of the os calcis, which could be cut with the knife (in the second case); and lastly, notwithstanding the bleeding fungus excrescences which formed on the bones (also in the second case), still the remnant of os calcis united firmly with the tibia and fibula. Lastly, one of the cases (the third) proves that the exarticulation at the ankle-joint after my method—at least in children and young people—may be undertaken even in cases of diseased ankle-joint, provided disorganisation has not extended too far over the soft parts about the articulation. In the boy in the second case, I found pus in the capsule during the operation, the cartilages softened and decayed, the ends of the bones also softened and in a state of fatty degeneration, yet the result of the operation was most successful."

Here, gentlemen, I must stop. I can tell you nothing of the results of the operation in this country, but I can repeat that in some of the cases where it has been said to have been performed, it most certainly was not done in the manner and with the precautions I have brought before you. Whether it has succeeded or not I cannot say, but I do say that in some cases it has not been fairly tested, and I think it is worthy of a full and fair trial. This is the reason why I have quoted so fully the precise words of the eminent surgeon whose name it bears.

## ORIGINAL COMMUNICATIONS.

### CASE OF ACUTE MANIA, WITH SOFTENING OF THE BRAIN,

AND SUDDEN DEATH, FROM THE IMPACTION OF A FIBRINOUS  
COAGULUM IN THE PULMONARY ARTERY.

By GEORGE ROBINSON, M.D.

ON December 29th, 1857, I was requested to visit Miss —, aged 29, whom I found talkative, restless, and excitable, but intelligent and capable of answering most questions correctly. She was tall, well-made, of the nervous temperament, had enjoyed good bodily health, and the catamenial function was quite regular. I was informed that from infancy she had been clever, but irritable and capricious; that during the last two years this irritability had increased, and that, though highly educated, she often exhibited the petulance of a child, and would even strike those around her. Two days previously, she had appeared more excited than usual, called at several places unnecessarily, and both mind and body were in a state of abnormal activity. A little aperient medicine was ordered, to be followed by a sedative mixture; she was allowed plenty of plain, nutritious food, of which she took a considerable quantity. During the two following days she continued in this state of excitement, taking food freely, sleeping two or three hours every night; but the mental disturbances had increased, as the incessant talking betrayed great incoherence in her ideas, and the existence of numerous delusions as to various persons being present in the apartment, &c. There was also a disposition to strike at those around her, and to destroy articles within reach. A suitable attendant was therefore procured, and remained with her constantly. The bowels acted moderately, she took food well, and there were no particular indications of debility or internal disease.

On January 2nd, the case presented all the features of acute mania, and it was the wish of her friends that she should be removed to my asylum at Bensham. In the meantime, cold applications to the head, which had previously been employed, were continued, a dose of the sedative mixture, equal to

gr. ss. of morphia, was given in the morning, without any apparent effect, as regards quietude or sleep. A turpentine enema was administered in the afternoon, and she took a considerable quantity of beef-tea and other food during the day. At 6 p.m. Dr. White and Dr. Dawson called for the purpose of examining her with the view of signing the requisite certificates, but were informed that she had an hour previously fallen into a calm natural sleep, and under the impression that this might be productive of a beneficial change, those gentlemen very properly declined to disturb her. At 9 p.m. I myself called, and, understanding that the sleep continued, also abstained from seeing her. It was arranged that another attendant and a servant should remain with her during the night, and we were to meet the next day and ascertain what effect the sleep had produced. Soon after 5 o'clock on the following morning (the 3rd) Dr. Dawson and I were hastily summoned, and found her dead. It appeared that she had continued to sleep until 11 o'clock on the preceding night, when she awoke, took some beef-tea, and part of an orange, and, after talking incoherently for an hour and a half, again fell into a sound sleep. The attendant and servant watched her carefully during the night, and observed her to sleep calmly until 5 o'clock, when she drew a few deep inspirations and expired.

The shock to all interested in the patient was necessarily very great, as nothing in her history or symptoms suggested the idea of an early and sudden death. I could only explain to her relatives, who were persons of intelligence and good sense, that sometimes death did occur suddenly, without any obvious cause, but that there was a possibility of an examination disclosing some unsuspected morbid condition. I further mentioned the additional light recently cast on the causes of sudden death, by the discovery of fibrinous clots obstructing the large blood vessels, and instanced the case of the late Duchess of Orleans. Having obtained the requisite permission, my friend, Mr. Bolton, House Surgeon of the Newcastle Infirmary, kindly undertook to conduct the post-mortem examination, and, as the weather was very cold, no perceptible decomposition had occurred when it took place on January 5th, fifty hours after death.

The head was first examined.

The brain appeared well developed, and the veins on its surface somewhat engorged. On attempting to remove it, the crura cerebelli were found to be so much softened as to render it difficult to lift the cerebellum simultaneously with the rest of the organ. This softening also affected, but in a less degree, the posterior columns of the medulla oblongata. The crura cerebri, and a small portion of the base of each of the anterior lobes, were also less firm than natural, and, as far as the somewhat imperfect light enabled us to judge, there was very little departure from the natural colour of the softened structures. There was no congestion or effusion at the base of the brain, or in the ventricles.

On removing the medulla oblongata, the processes of bone which are situated on either side of the basilar groove of the occipital bone were observed to be unusually prominent, and that on the left side was developed almost to a point. These processes were in close contact with the posterior columns of the medulla oblongata, the anterior columns resting on the groove between them.

The chest was the only other part of the body examined.

The lower lobe of each lung was much congested; that on the left side being less firm than natural; but, with this exception, the lungs were free from disease. The right auricle of the heart was enormously distended with dark blood, suspended in which were some fibrinous coagula; and on examining the pulmonary artery it was found completely filled with a long firm fibrinous coagulum about four inches in length, which, when drawn out, exhibited the bifurcation of the vessel, and the separation of one of its primary divisions into two secondary branches.

In this case the conclusion that death resulted from obstruction of the pulmonary artery appears obvious, and the very circumstance of its thus occurring without previous symptoms of disordered circulation may suggest the propriety of great caution in similar cases, on the part both of the Medical practitioner and the public, in referring the fatal event to any assumed cause. It is not difficult to imagine circumstances under which blame might be unjustly attached to the remedies employed, or to persons having charge of the patient, and in the present instance it was a source of

satisfaction to all concerned that this unfortunate lady had not been removed to the asylum.

I cannot but connect the softening of the brain at that particular part with the abnormal development of the bony processes alluded to. The relative size and condition of these processes in cases of mental disease appear to me worthy of observation from their intimate anatomical relation with important structures, and from the ascertained influence of prominent spiculae of bone in disordering the cerebral functions. It may also be a question in this case whether the congestion found in the lower lobes of the lung may not have been connected with the diseased state of the medulla at the point of origin of the pneumogastric nerves.

Newcastle-on-Tyne.

ON THE

## TOXICAL AND MEDICINAL PROPERTIES OF NITRATE OF OXYDE OF GLYCYL.

By A. G. FIELD, F.R.C.S.

Late Demonstrator of Anatomy at St. George's Hospital Medical School.

In the evening of the 3rd of February, 1858, I was conversing with a homœopathic practitioner, when he mentioned a medicine which possessed peculiar and extraordinary qualities, some of which he described as having affected himself, though he had taken it in very minute quantities. I laughed at his credulity, and offered to take as much as he pleased, upon which he let two drops of what he called the first dilution of glonoine fall on my tongue. After swallowing this small quantity of fluid—I was assured the quantity did not exceed two drops—I asked what effects I must expect, but was told to wait and observe for myself. I then purposely conversed on other subjects. In about three minutes I experienced a sensation of fullness in both sides of the neck, to this succeeded nausea, and I said, "I shall be sick." The next sensation of which I was conscious was, as if some of the same fluid was being poured down my throat, and then succeeded a few moments of uncertainty as to where I was, during which there was a loud rushing noise in my ears, like steam passing out of a tea-kettle, and a feeling of constriction around the lower part of my neck as if my coat were buttoned too tightly; my forehead was wet with perspiration, and I yawned frequently. My intellects returned, however, almost immediately, and I remember saying, "This has nothing to do with homœopathy, but it has to do with a very powerful poison; there are more things in heaven and earth than are dreamt of in the philosophy of some of us." I also reproached my friend for not having tested the anæsthetic power of the medicine, by inflicting a slight wound on me. I need scarcely say I am this minute in my description of what occurred, that an accurate idea may be conveyed of the actual effect produced on me, as well as to justify the uses to which I have since put the medicine. When these sensations had passed off, which they did in a minute or so, they were succeeded by a slight headache, and dull heavy pain in the stomach, with a decided feeling of sickness, though without any apprehension that it would amount to vomiting. I lay on a sofa, feeling rather languid, but talking cheerfully, conscious at the same time that I could very well exert myself both mentally and physically, if I liked, but that it was more pleasant to be idle. This condition lasted about half an hour, at the end of which I was quite well, and walked home, a distance of half a mile, with perfect comfort. I slept soundly from one o'clock till six, when I was called up, having a slight amount of general headache, but not such as I should have regarded but for the recollection of last night's adventure.

The physician to whom I am indebted for this overdose told me, that when his first impression that I was shamming had passed off, my condition caused him the greatest alarm, for he really thought he had killed me. I learn from him that my head fell back, my jaw dropped, I was perfectly white, breathing stertorous, and no pulse at the wrist for the space of about two minutes. He immediately rushed to a closet, and procured some stimulant, which he poured down my throat. I had never been in better health and spirits than on the day of

this occurrence, and had taken nothing for hours but a little cold tea.

This same first dilution of glonoine consists of one drop of a peculiar chemical compound, dissolved in ninety-nine drops of rectified spirit; and glonoine itself I learn to be a nitrate of oxyde of glycyll, prepared by adding nitric and sulphuric acids to glycerine, the temperature of the fluids being kept down by a freezing mixture.

My own personal experience of the very marked and peculiar effects produced by this drug made me anxious to test its qualities still further. As a direct sedative to the nervous system without possessing any stimulating or permanently depressing qualities, without affecting secretion, together with its power of subduing muscular action, it appeared to promise to become an invaluable agent in the treatment of a large class of nervous and spasmodic diseases. By a strange perversion of all reason, as it appears to me, my friend, who is an enthusiastic disciple of Hahnemann, began to rejoice, when all appearance of danger had passed, that he had discovered what he considered a splendid remedy for apoplexy, on the principle of *similia similibus curantur*. I leave him to the enjoyment of his opinions, feeling only grateful that he did not give me a second dose to cure me on a like principle, while I consider the best mode of applying the drug in a precisely opposite direction. With this object I procured some of the first dilution of glonoine from a homœopathic chemist, and proceeded to institute a series of experiments before applying it to the treatment of disease.

Anxious to inform myself on the effects of a smaller dose, I got a Medical friend to join me. We each touched our tongue with the cork moistened with glonoine solution, and recorded the sensations produced by it. They were nearly as possible identical—a sense of constriction of the neck, slight nausea, with fullness, and some pain in the head, as if the brain were expanding. But I think my friend must have experienced more decided effects than I did, for he declared he would never take any more. The sensations lasted about five minutes, and then passed off without leaving any unpleasant effects.

Animals, as far as my experiments have extended, appear to be almost unaffected by this drug, which acts so powerfully on the human organization.

I have repeatedly given it to cats, rabbits, and other animals in doses varying from two to thirty drops without producing any immediate effect. One rabbit had diarrhoea an hour after, and the cats appeared cold and lazy all the next day. Some smaller animals, such as mice and pigeons, died after having taken the glonoine some hours, but they appeared to have suffered from alcoholic poisoning rather than from any symptoms at all resembling those produced by the glonoine on the human subject.

Disappointed in my endeavours to gain any information from experiments on animals, I still thought I had seen and felt enough of the physiological action of the medicine to justify my cautiously employing it in the treatment of disease.

Case 1.—Mrs. L., aged 68, had for some days been under treatment on account of a very painful nervous affection, which she designates spasms. This recurred regularly every three hours, and is described by herself and her attendants as most distressing, and my own observation of one or two seizures fully bears out their statements. Each attack commenced suddenly with intense pain in the epigastrium, extending up to the top of the chest, and then down the inner side of the left arm; it lasted about half an hour, and then subsided, leaving her exhausted, but otherwise well in the intervals. They recurred during the night with equal regularity. She was at the same time the subject of uterine derangement. Fœtid ammonia, assafetida, chloroform, valerian, hyoscyanus, camphor, and prussic acid, with counter-irritation, having failed to give her relief, I had recourse to morphia every two hours, which relieved her only after several doses had been taken, and partial narcotism had been produced. She would then enjoy a few hours' peace; but the attacks always returned when the influence of the morphia had passed off.

Feb. 6th.—She had slept well all night from the morphia which had been taken in the previous twenty-four hours, and was awoke in the morning of this day by one of her painful attacks; but it yielded in three minutes to a quarter of a drop of the solution of glonoine in a dessert spoonful of water. After this she had four more attacks before noon. For three

she took the same medicine, and was quickly relieved; but having exhausted her supply when the fourth occurred, she suffered as much as on former occasions.

My daily notes of this case are nearly a repetition of what I have just stated, till the evening of the 10th, when she appears to have taken an over-dose, which produced effects very similar to those from which I suffered on the 3rd. This gave rise to so much alarm, that she refused to take any more. I therefore again had recourse to the morphia; but she suffered so severely the next day and night, that she begged to be supplied with the glonoine again, and no sooner had she taken it than relief was obtained. The dose has been continued every four hours, with the happiest results. Her attacks now are reduced to two or three in the twenty-four hours, and always readily yield to the quarter of a drop of solution of glonoine. The only other treatment she has required has been a few ten-drop doses of the tincture of *Canabis indicus*, to relieve uterine hæmorrhage.

**Case 2.**—Mrs. W. had suffered severe pain from a decayed tooth for several hours. The pain was so great, that she would gladly have had it extracted; but her dentist was anxious to preserve it. In the evening she begged me to give her something, for she said, "It cannot be made worse." I placed about half a drop of the solution of glonoine (1 per cent.) on her tongue. Soon after she experienced a pulsation in the neck, fullness in the head, throbbing in the temples, and slight nausea. The toothache subsided, and she became partially insensible, disliking very much to be roused. When fully sensible she had headache, but the toothache was gone. Mrs. W. remarked, "Certainly that medicine allays pain wonderfully." She slept unusually well that night, and experienced no ill effects in the morning.

**Case 3.**—Elizabeth M., a stout, healthy young woman, had severe tooth-ache. I was applying a very small piece of lint dipped in glonoine solution (1 per cent.) when it accidentally fell into her mouth and was swallowed. In about five minutes, after feeling giddy and sick with headache, she became insensible. Her countenance, naturally florid, was unaltered, breathing tranquil, pulse full, and rather quickened. Knowing, as I did, that she had taken but a small quantity of the drug, I kept my finger on her pulse, and allowed myself time carefully to observe her condition before applying a restorative. I tested her sensibility to pain, and called loudly to her, but without producing any impression. Directly I detected a slight failure in the pulse, in about three minutes after insensibility commenced, she had some stimulant poured down her throat, when she quickly recovered. Some headache was complained of, but the toothache was cured. The next morning she was quite well.

**Case 4.**—Mrs. R., aged 45, pale, anæmic, with feeble circulation, has for the last month suffered from headache, daily increasing in severity. When I first saw her, February 15, she had had leeches applied to the temples, and had taken drastic purgatives, since which the pain had been much worse, and she could not sleep. I gave her a quarter drop of glonoine solution in coloured water every four hours. On seeing her the next day, she expressed the greatest gratitude for the relief the medicine had afforded her, and she said her head was much better after taking the first dose, and she slept four hours. The glonoine was of course given only as a palliative in this case, while iron and generous diet were relied on as a means of effecting a cure.

I have not yet met with one well-defined case of neuralgic or spasmodic disease in which this medicine has failed to afford relief. No vague, over-sanguine expectations are entertained of its power to cure disease where spasm or pain are but symptoms, excepting only in those cases where these consequences themselves become the cause of death, their cause being of a transient nature, and liable to subside if the patient's life can be maintained for a certain time, such as temporary irritation of a nervous centre, or inflammation of such a part, which might terminate in resolution or be subdued by remedies, if existence were prolonged sufficiently for their action; and also in cases where we may suppose symptoms such as spasm may react on their exciting cause, preventing the necessary tranquillity for recovery, the offspring, as it were, maintaining its parent. With such a remedy may we not look forward hopefully to the treatment of tetanus, hydrophobia, and other similar diseases?

28, Old Steine, Brighton.

## A PROTRACTED CASE OF OPIUM POISONING.

By W. BOYD MUSHET, M.B. Lond.

Julia Lyons Kavanagh, a flabby, ill-nourished child, about 3 months old, was brought to me at 3 p.m., on September 14, 1857, labouring under symptoms of poisoning from opium, which had been administered about two hours previously.

The aspect of the child was calm, pale, deathly. It was completely comatose, unrousable, insensible to sharp pinching, not convulsed, but arms rigid, fingers clenched, nails not livid; lips pallid, mouth occasionally puckered, not drawn; lids closed, pupils contracted to a point, insensible to light; eyes supraverted, and divergent; legs slightly drawn up; extremities warm; skin not perspiring; pulse very feeble, difficult to count; respiration, 34 in the minute, slightly stertorous, with inspiration of a stridulous character. Five grains of sulphate of zinc were administered in warm water, and the fauces tickled with a feather to produce vomiting. In a few minutes the emetic was repeated, and slight (colourless) vomiting ensued. The stomach-pump (a catheter) was not resorted to, in consequence of the early age of the patient, which rendered its introduction difficult and dangerous, with the additional risk of instant asphyxia, as the child was collapsed and sinking. Moreover, the poison had been swallowed two hours, and had been absorbed from the stomach, as manifested by the intensity of the coma. The child was next undressed, wrapped in flannel, and agitated by roughish nursing, alternated by cold affusion, friction, and slapping with a wet towel. Meanwhile the electro-galvanic apparatus was prepared, previous to which two ounces of warm coffee, a teaspoonful of brandy, and half-a-teaspoonful of sal volatile, were injected into the rectum. Respiration became more markedly stertorous, and death appeared impending, as the treatment produced no result. Galvanism was now used, but produced scarcely any contraction of the muscles, although so strong a current was maintained as to be unpleasant to those around. Respiration took place at longer intervals, and no benefit being derived from galvanism, it was discontinued, and more coffee, brandy, and ammonia introduced per rectum, but the child became colder, and appeared gradually to cease breathing. Slight convulsion of right arm, with spasmodic drawing of the mouth upwards to the right, now (6 p.m.) took place, the rectum discharged its contents, and the child became cold, and apparently dead to all around. On opening the flannel a few minutes afterwards, it was observed to gasp for breath, when it was taken to the fire, again rubbed, and some warm milk and brandy were injected. The child remained insensible, and in an almost lifeless state until 12 p.m., when respiration was reduced to two or three in the minute, the eyes were much sunken, and death appeared to be at hand. More milk and brandy were administered, warmth and friction were continued, and in a short time the respiration increased in frequency (32), and the pulse and slow regular action of the heart could be distinguished; surface and extremities became warmer; pupils remained contracted; coma still profound, and no result from pinching; power of deglutition remained lost.

September 15.—Brandy and milk again injected at 3, 6, and 9 a.m., at which latter time the respiration became more natural without stridor or stertor. Pulse tolerably good, 136. Slight movement on pinching, but no cry uttered. Surface warm, dry. Pupils a little more dilated; no lividity of general surface, lips, or nails. About two ounces of milk injected at 11 a.m. and 1 and 3 p.m.

At 3 p.m., twenty-four hours after admission.—There are very slight spontaneous movements of limbs. Urine several times passed, and two or three motions. Milk to be injected hourly, as the child cannot swallow.

6 p.m.—Breathing hurried without stertor; surface warm; complete unconsciousness to external impressions; eyes less turned up; pupils as in the morning.

7 p.m.—Râles in throat; apparently sinking; eyes natural in position; pupils still contracted; no lividity. Attempt to give fluids by mouth causes cessation of respiration, and they return partly through the nose.

12 p.m.—Large mucous râles, and death imminent; pupils still contracted; no convulsion; surface warm; pulse dis-

tinguishable, laboured; no lividity; complete unconsciousness; brandy and milk at intervals per rectum.

16th, 9 a.m.—Much the same, but rales less noisy; pupils rather more contracted than last evening; unconsciousness as before; surface cooler; no lividity; milk administered by rectum; partly returns.

10.20 a.m.—Milk and brandy again injected; immediately rejected; rales increasing, and respiration less frequent.

1.50 p.m.—Milk and brandy administered; partly retained; respiration infrequent and laborious; no rales; pupils as before.

7 p.m.—Respiration very infrequent, five or six per minute, suspicious in character, occasional intervals of a minute between each inspiration; face calm, expressionless; pupils moderately dilated, but probably not to natural extent; surface cold; no lividity; absolute insensibility to external impressions, but the child has uttered three or four distinct but feeble wails or cries—the first sound since admission; pulse imperceptible, but heart can be distinguished by ear; limbs completely flaccid; has passed much water and yellowish motion; milk and brandy injected; mostly returned.

9.20 p.m.—Death fifty-four hours after admission, and about fifty-six hours after ingestion of the poison, preceded by clapping of the hands and general convulsion.

*Post-mortem examination, 18 hours after death.*—Weather warm. Pupils moderately dilated, right rather more than left; aspect calm; general surface and lips pale; sufflation across loins and occiput. Rigor mortis tolerably well marked in limbs, most on right side of the body; fingers clenched; thumb of right hand drawn across palm; nails livid. Very little subcutaneous fat.

*Head.*—Reflected scalp, very pale; calvarium well ossified; dura mater natural. A small fibrinous clot in posterior part of superior longitudinal sinus. Surface of hemispheres rather paler than natural. No subarachnoid effusion. Substance of brain, for the age, firm, and section presents a very pale, almost anæmic appearance. Whole of brain on section very pale and puncta-vascular generally not perceived. Ventricles merely moistened with fluid. Choroid plexus very pale. About 3j. of sanguinolent serum at base; lateral and other sinuses filled with dark semi-coagulated blood.

*Chest and abdomen.*—Pharynx and œsophagus pale. Stomach, no special (but cadaveric) odour, pale, rugose, neither softened nor eroded; contains about 3ij. of brown tenacious fluid. Small intestines congested, but mucous surface not ulcerated; large intestines pale, and contain feculent fluid matter, with small whitish particles, apparently of biscuit or cake. About 3j. of serum in peritonæum. Mesenteric glands, many nearly of the size of a pea. Spleen pale; kidneys pale, lobulated; liver healthy. Some very tenacious dark bile in gall-bladder. Bladder empty.

Thymus not so broad, but lower than usual. Lungs anteriorly healthy; left lung posteriorly, especially lower lobe, in state of collapse; right lung exhibits same character, but posterior part of lower lobe is non-crepitant, hepatized, reddish, hard to the feel, but not granular; sinks at once in water.

Larynx healthy. Trachea and divisions much injected, and containing tenacious reddish, non-frothy mucus. Right pleura healthy, but about 3j. of reddish serum on left side of chest. Heart healthy; about 3ss. of fluid in pericardium: fibrinous clot in right auricle; ventricle empty; left cavities contain a little dark semi-fluid blood.

*Remarks.*—The foregoing case is especially interesting from the fact, that no case ultimately proving fatal is recorded of so protracted duration. Forty-eight hours is the longest period hitherto known in fatal cases, and the particulars of these have not been detailed. They therefore lose their interest. Dr. Christison mentions twenty-four hours as the longest term in his own experience, death usually occurring within eighteen hours.

When the tender age of the infant, its ill-nourished condition, and the unpromising nature of the symptoms from the outset, are taken into consideration, I think the opinion is justified, that the period which elapsed before death was due rather to the assiduity which was evinced in the remedial measures adopted, than to the smallness of the dose. Although its amount could not be ascertained, it was, nevertheless, sufficient to induce intense coma, and it may consequently be presumed, speedy death, had the case been uninfluenced by treatment. If this be admitted, it warns us

to persist in our endeavours in cases apparently hopeless, at the same time reminding us to resort early to nutritive and stimulating injections, if the power of deglutition be lost, as marked benefit, indicated by increase of warmth, pulse, and respiration, followed their exhibition. The latter measure especially obtains in proportion to the tender age of the patient, explicable on physiological conditions. The absence of convulsion and lividity deserve notice. Also the insusceptibility of the infant to the galvanic stimulus (? due to paralysis of the muscles from the poison introduced into the circulation). The stridor present is also worthy of note. It appears to be an occasional symptom in opium-poisoning, as it was observed in an infant treated by Mr. Colahan, whose case is recorded in "Taylor on Poisons."

With regard to the post-mortem appearances, the pulmonary collapse was no doubt, at least partly, of some duration, and accounted for the pallid and weakly appearance of the child, being the result of defective nutrition from imperfect oxygenation of the blood. The pneumonia, I conceive, was consequent on, and not antecedent to the symptoms of narcotism. It appeared to be recent from its limited extent, its situation at the posterior part of the lower lobe, the absence of symptoms during life announcing its existence, and of any trace of the third stage of the disease, together with the information that the child was well previous to the administration of the drug. The anæmic condition of the brain was somewhat singular, but it must be remembered that the child survived fifty-six hours, and that congestion might have existed at an earlier period, although it is not improbable that the general pallor from the condition of the lungs was participated in by the cerebral organs, and obviated the ordinary pathological evidence of the poison.

*Note.*—No poison was detected on analysis of the stomach, but the fluid in the bottle, (about ten minims) when treated in a glass scale with tincture of sesquichloride of iron, gave tolerably evident rusty colour, (meconate of iron,) which was not decolorised by solution of bichloride of mercury. Another portion of the rusty coloured fluid treated with solution of acetate of lead, gave scanty whitish granular deposit, (meconate of lead.)

Milton-street, Dorset-square, Nov, 1857.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### THE ROYAL LONDON OPHTHALMIC HOSPITAL.

#### REPORT OF OPERATIONS PERFORMED FROM FEB. 1st TO MARCH 1st, 1858.

By Dr. C. BAKER, Registrar to the Hospital.

##### EYELIDS.

Two cases of entropium of the upper and lower lid, treated by grooving the anterior surface of the fibro-cartilage near and parallel to its palpebral edge; and one case treated by removing the portion of the lid which includes the eyelashes. In the three cases bleeding has been prevented during operation by the compressorium forceps. One case in which the palpebral aperture was narrowed for the reception of a glass eye, by removing an oval piece of the conjunctiva of the lower lid. One case of injury to the eyelids, producing paralysis of the palpebræ and laceration of the lower lid; the latter had been torn just to the inner side of the lower lachrymal punctum, where it is peculiarly apt to give way when mechanical force acts on the lower lid. The entropium of the lower lid has been remedied by excising a V-shaped piece of the everted portion, including the cicatrix, the cut surfaces then being brought together with sutures, and its palpebral margin carefully adapted.

One case of ectropium with everted lower lachrymal punctum, has been satisfactorily treated by Mr. Critchett's plan of excising the posterior lip of the slit-up lachrymal canal.

##### STRABISMUS.

Fifteen cases of internal strabismus. In thirteen of them both internal recti divided subconjunctivally.

A ready explanation has been afforded by the ophthal-

moscope in some cases in which vision was very defective. Where both recti had been divided the restoration of symmetry was most complete. In one case of internal strabismus, which had been operated upon three years ago by the subconjunctival method (?) slight external strabismus began lately.

The case does not invalidate the value of the operation, since there is a disease of the retina, and there have been repeated divisions of either internal rectus at different periods. Both external recti were divided after the old method.

#### CORNEA.

Two cases of staphyloma of the anterior portion of the globe (consequent on injury) were treated by removal of a part (cornea) of the staphyloma with the ~~cataract~~ knife. Troublesome bleeding and sickness followed the operations, although "wet lint" had been put on immediately, and pressure applied."

The patients left the Hospital, the one on the fifth, the other on the fourteenth day after the operations. The blood which fills the globes will be absorbed gradually, and after long and troublesome treatment a glass eye will be worn. The cases form good contrasts to the simplicity of excision.

One case of conical cornea treated by Mr. Critchett by extraction of both crystalline lenses. The right eye had been successfully operated upon two months ago. The left lens was broken up with the needle on the 22nd of January. On the 23rd, the swollen lens substance was removed by a small corneal wound.

The consequent pain and irritation (treated by leeches and hot fomentations) subsided after a fortnight, when the patient left the Hospital. Three weeks later she was able to read ordinary type with a strong concave glass (No. 17). The defect of vision commenced after a severe illness (affection of the spine ten years ago).

#### IRIS.

Two cases of detachment of posterior adhesions of the pupillary margin, consequent on specific iritis.

No inflammatory symptoms were present at the time of operation. Both patients (Mr. Streatfield) were much improved—the one who could see lines on a printed page before the operation, reads ordinary sized type two weeks after the operation. The broad needle and blunt spatula were used as usual.

One case of detachment of adhesions of the iris to a corneal cicatrix preparatory to the treatment of traumatic cataract.

One case of foreign body in the iris. It had entered the eye the day before, probably through the sclerotic, the pupil was contracted, and a small whitish nodule of lymph was visible near its inner pupillary edge; the irritation and conjunctival redness were considerable. Mr. Bowman made a small corneal incision at its outer edge. On extracting the nodule of lymph with the canula forceps, a very small black body fell into the anterior chamber, and was removed with the scoop: four days later the eye had returned to its normal state.

Four cases of artificial pupil for corneal opacities.

When these were central the pupils were formed opposite the inner corneal edge. In one case a silk ligature was placed round the portion of iris withdrawn, with the view of making it form a nodule outside the cornea, and preventing its slipping back. The silk would not hold the rotten iris tissue.

In the other cases the portion of iris was either left in the corneal wounds, or partially removed with scissors. In a case (patient of Mr. Wordsworth) of adhesion of the whole pupillary edge to a corneal cicatrix, part of the iris was detached with the broad needle, withdrawn with the hook, and snipped off.

Three cases of excision of the upper fourth of the iris for glaucoma. In two of them both eyes were operated upon simultaneously; hardly any inflammatory symptoms followed the operations, but vision was not improved. The ophthalmoscopic appearances in all were cupping of the optic nerve entrances, partial loss of transparency of the retina, etc. The patients were of the ages of 70, 64, 60; vision had been lost gradually, and without pain; the consistence of three of the globes was normal; three were harder; the pupils were inactive, their arcæ greenish; no enlarged ciliary veins.

#### CRYSTALLINE LENSES.

Two cases of uncomplicated cataract at the ages of 60 and 32. The latter case had been operated upon for internal strabismus a week before. In both cases the lens was removed

through an upper corneal section; in the one the iris was wounded, in the other some vitreous came forward before the escape of the lens. The patients were able to read common type on leaving the Hospital three weeks after the operations.

One case of extraction has been performed on a patient, aged 45, whose eyes spontaneously inflamed ten months ago. At the time of operation both pupils were occluded by a greyish-white exudation, the anterior chambers were large, and the aqueous yellowish, without other inflammatory symptoms. The right eye perceived; the left recognised large objects. The left lens, which was slightly yellowish, transparent, and of the consistence of jelly, was extracted. The adherent rigid pupil prevented its easy escape. On the fifth day the corneal section had completely united; a grey membrane, resembling detached retina, was perceptible through the pupil, which was central, ~~immovable~~, and hazy. The patient has fair perception of light. A similar case (of a patient aged 19) has been treated by linear extraction. He left the Hospital with a central black pupil, nineteen days after the operation. Vision (fair perception of light) was not improved; a grey non-vascular membrane behind the capsule intercepted the light of the ophthalmoscope. One case of congenital cataract (aged 23), in which both eyes had been repeatedly operated upon elsewhere (eighteen years ago). Both globes were oscillating, the right staphylomatous; the left showed, on dilating the pupil, a flat, waxy-looking lens. The patient had perception of colours, and no inflammatory symptoms in the eye. The greater part of the lens was removed with canula forceps and scoop, through a small corneal opening. The right globe was excised. The eleventh day after the operation the remaining swollen flocculi of lens substance were removed (under chloroform), and a fortnight later the patient recognised the different fingers.

In one case of double extraction (of July last), the false membrane behind the pupil was opened out with the needle.

#### EXCISION OF THE GLOBE.

Ten cases. Of these, three were for staphylomatous enlargement of the globe. Four cases of acute inflammation of the globe, in which vision had been destroyed by former inflammatory attacks. Two cases without active inflammatory symptoms in the diseased eyes, which were removed to prevent their compromising the healthy eyes. One case of some congenital disease of the deeper parts of the globe, with loss of vision, and recent inflammation affecting the sound eye. In several cases the outer canthus was divided, to allow the staphylomatous globe to press through the palpebral aperture. The bleeding (generally inconsiderable) is best stopped by continual application of cold water, keeping the palpebra open with the speculum. The introduction of lint does not answer as well.

Of the above globes, three are particularly interesting. One (excised by Mr. Dixon), inflamed during the recovery of the other eye from extraction. Cataract had existed in both, and had been successfully extracted from the right eye. Three weeks after the operation the left eye inflamed, pain, etc., continued for two months, and the globe was removed to save the right eye. Mr. Dixon divided conjunctiva, superior, inferior, and internal rectus (without using the hook), and the optic nerve. The globe advanced out of the orbit, and the external rectus and remainder of its soft attachments were divided. A quantity of lymph had been deposited throughout the vitreous humour, and by its changes, shrinking, etc., had detached the retina.

In a case (of Mr. Poland's) excised for melanosis of the globe, the development of the cancerous growth (from the choroid near the yellow spot) was distinctly seen. The melanotic mass consisted of millions of transparent tubes, which, commencing in the choroid, branched out, and opened into the eye; to the different branches long oval cells were attached; the branches and cells were surrounded by rust-coloured blood corpuscles, and pigment debris. The growth had filled the globe within a week, and had caused effusions of lymph on the outer surface of the sclerotic beneath the insertion of the oblique muscles, which rendered excision somewhat tedious. Six hours later, the contents of the globe formed a smeary chocolate coloured mass, none of the tubes being recognisable.

In the globe, which had been removed for some congenital defect and pain, etc., by which it compromised the good eye, an irregular shaped dead white mass (the lens) had been visible through the cornea and dilated pupil, suspended in

the transparent ciliary pigment. On opening the globe, a fibrous cord was found attached (on the surface of the retina) to the portion round the yellow spot and entrance of the optic nerve, and thence stretching through the vitreous humour, was inserted into the hyaloid fossa, to whose anterior surface the dead white shrivelled lens was firmly adherent, so that, on dragging it with a needle, the retina was detached to the extent of the insertion of the fibrous cord. The latter inclosed numerous blood-vessels, most of which branch backwards before reaching the hyaloid, and form the central point of insertion for the transparent strings which originate from the inner surface of the hyaloid, and by their number appear to cause the consistence of the vitreous humour.

Total of major operations, 71.

## ST. BARTHOLOMEW'S, GUY'S, AND OTHER HOSPITALS.

### NOTES ON THE ABSORPTION OF PUS, CONSIDERED IN ITS RELATIONS TO PRACTICAL SURGERY.

In the early periods of histological research it was a question of frequent debate as to whether true pus could ever be re-absorbed. A pus corpuscle was, it used to be asserted, too large a body to be capable of being taken up either by lymphatics or veins, and among theorists there was a strong disposition to maintain that serous fluids alone could be removed without breach of any part of their containing sac. This is now generally admitted to have been the most puerile logomachy. That pus corpuscles as such cannot penetrate unbroken membranes is certain, but that they may disintegrate, and after having thus been resolved into their molecular and fluid elements, that they may be wholly re-absorbed, is now acknowledged by almost all. The state of the case is with them exactly as it is with those of blood; and every one will grant that the latter fluid is easily susceptible of absorptive removal. Assuming, however, the general principle to be granted, there still remain several questions of great, and almost daily interest to us all in connexion with this matter, about which opinions are by no means unanimous. Does the absorption of purulent collections practically often occur? Under what circumstances may it be hoped for? By what treatment may it be favoured? When it does occur, is any injurious influence exerted upon the system?

In the hope of contributing data towards the solution of some of these, we have thrown together the following brief and very imperfect notes:—

And first, in reference to the frequency or otherwise of the absorption of large collections of pus, let us quote the opinion of an exceedingly clever pathologist and surgeon. (a) "In the surgical treatment of large chronic abscesses, it used often to be tried to obtain cure without discharging the matter, by promoting (as was then thought) the absorption of pus. Bleeding or purging, or vomiting or sweating, or other evacuations were had recourse to, and not infrequently the fluctuating tumour vanished. But this was only for a time. A large proportion of the serum had been withdrawn from the contents of the abscess, and these had been reduced to little beyond cells; but as soon as the blood had recovered its natural constitution, these cells (just like the nucleated cells of glands) again exerted their power, and surrounded themselves with their natural atmosphere. Accidental circumstances will often act like the treatment to which I have referred, and will reduce the fluidity of pus so that an abscess apparently vanishes; but the cells may remain quiescent for an indefinite time, and may presently again surround themselves with fluid blastema, forming the same amount of pus as at first. The perfect and permanent absorption of an abscess consisting not only in the removal of its serum, but in the destruction and dissolution of its corpuscles, so that the part shall retain no tendency to the re-accumulation of its previous contents; this, I am persuaded, is among the very rarest occurrences in surgical practice."

There is much of truth in these remarks, although we cannot but think them too strongly put. Without admitting with Mr. Simon that the cells of pus tend to secrete around themselves a fluid blastema by any similar power to that possessed by nucleated gland-cells, there can be no difference of opinion as to the fact that the first stage in its absorption is the removal of its fluid, and that its solid constituents remaining behind give a great tendency to relapse. Do they not effect this more by the irritation of foreign material tending to relight the original inflammation? We do not speak of cases in which the serous part of an abscess has been partially drained off under the influence of violent diuresis, and the refilling of which, when the circulating fluid has been again supplied, is fully explained by the law of endosmosis, but of those cases in which the absorption has been slow, and coincident with improving health. In these latter is there not enough in what is known in the liability of all inflamed tissues to again take on the diseased action, especially when a permanent source of irritation remains behind, to save us from the necessity of assuming that pus-cells possess an active secreting function? But enough of speculation; let us pass on to the record of facts.

NOTE I.—Ophthalmic practice furnishes us with by far the best and most irrefragable examples of the absorption of pus. We recollect hearing Mr. Critchett declare to his clinical class at Moorfields, that he had over and over again witnessed the complete removal of undoubted pus from the anterior chamber of the eye. We mention his name only because we chance to have a clear recollection of a most positive expression of this opinion, not because he is at all peculiar in holding it. All ophthalmic authorities, we believe, admit the possibility of the absorption of hypopyon. In not a few cases what is called pus in the anterior chamber of the eye, is, in reality, a mixture of pus and lymph, but still there can be no cavil, that it is not unfrequently a homogeneous fluid, capable of displacement by any motions of the globe, and in no respect distinguishable from true pus. As the cornea, in these cases, often retains perfect transparency, the progress of the absorption may be easily watched. It is often very rapid, almost as much so as that of blood. The only remark to be made as to the treatment which favours its absorption is, that it is usually that which subdues the inflammation which had caused its secretion.

NOTE II.—The absorption of fluid from inflamed glands is a very frequent occurrence. As to whether such fluid is pus or not, there is, of course, room to doubt. That it is so, however, in a vast majority of cases, few reasonable men will deny. How seldom do we, on using the lancet to a bubo, find its contents merely serous. Yet how often, after fluctuation has been plainly detectable, do we witness its disappearance without any evacuation. We published, some years ago, a note on Mr. Hilton's treatment of buboes, and stated that that gentleman held that absorption might almost always be procured. His method of treatment consists in the application, over the whole surface, of a saturated solution of nitrate of silver, containing a few drops of strong nitric acid. It is a most powerful counter-irritant, and usually vesicates sharply. The principle is the same as that adopted by many other surgeons. Mr. Lloyd, at St. Bartholomew's, for instance, often orders a blister over an abscess which it is wished to have absorbed, and the strong solutions of iodine are favourites with many for the same purpose. Both Mr. Hilton and Mr. Lloyd we have repeatedly heard speak most positively as to the practicability of procuring the absorption of the fluid from glandular abscesses, especially from venereal buboes. We have ourselves repeatedly known it to occur, and many of our readers will have, doubtless, also done the same.

NOTE III.—A lad was some years ago under Mr. Birkett's care in Guy's, on account of a large collection of fluid in the front part of the thigh. It was doubtful as to what was its cause, as there was no positive evidence of diseased spine, hip or femur. That it was either of lumbar origin or an abscess in the cellular tissue, were the most probable conjectures. Mr. Birkett one day directed our attention to the case as an example of the absorption of pus, stating that there had at first been "half a pint, if any." Its removal had been slowly effected, nine months having been occupied in the process. The local treatment had consisted in painting the part with iodine. As absorption became complete, the parts around assumed an indurated and cicatrix-like

(a) Simon's Lectures on Pathology, page 115.

condition. The lad had greatly improved in health whilst under treatment.

**NOTE IV.**—In cases of carious disease of the vertebrae, there is rarely any doubt as to the nature of the fluid secreted. It is almost invariably purulent. We can indeed scarcely suppose that extensive destruction of the vertebral bodies can take place without the formation of an abscess. Yet how frequently do we see cases of spinal curvature in which no scars exist! A very good example of this we made a note of in November, 1862. The patient was a man under Mr. Lloyd's care in St. Bartholomew's, for diseased ankle. He was bent double by an angular curvature of the dorsal spine, but the anchlosis of the bones had long been perfect, and he enjoyed good use of his limbs. There could be no doubt that the bodies of several vertebrae had been destroyed. He stated that the disease had begun at the age of five, and that for some time he had been paralysed in his legs. He was quite certain that there had never been any discharge whatever from any part. We examined his back and sides carefully, and could find no trace of a scar. An almost precisely similar instance came under our notice at the Victoria-park Hospital, some years ago, in a man under Dr. Bennett's care for diseased lungs. In these, however, it may be alleged by the sceptical that there is no proof of an abscess having ever existed. The following is less open to doubt:

**NOTE V.**—In 1856 we saw a young gentleman of delicate family who was invalidated by supposed spinal disease. In his left lumbar region, just beneath the short ribs, was a prominent, freely-fluctuating swelling, and there was an angular prominence of one of the lower dorsal vertebrae. The disease had existed several months. A physician as well as another surgeon saw the case, and no one doubted as to the existence of a large collection of matter. Counter-irritants (nitrate of silver) were fully employed, and cod-liver oil and tonics were given. By slow degrees the fluid diminished, and at length finally disappeared. The patient is at present in very fair health, and although the angular projection of the vertebra still remains, yet he is so little inconvenienced that he is accustomed to enjoy very free exercise of all kinds. It is now more than a year since all evidence of the existence of matter ceased to exist, and there can, therefore, be little doubt but that the absorption is permanent.

**NOTE VI.**—A woman was treated under Mr. Hilton's care, in Guy's, about two years ago, for a peculiar form of contraction, with partial paralysis of the arm. An abscess, or, at least, a large collection of fluid, attended with surrounding inflammation, formed in the front aspect of her fore-arm. It was quite expected that this would have to be opened; but, contrary to what was looked for, it gradually subsided, and underwent complete absorption. Some months later the arm was amputated, and, in the site of the supposed abscess, was found still existing a small quantity of yellow curdy material, quite dry, and exactly resembling the remains of concrete pus. Mr. Hilton at the time directed especial attention to this interesting case, as affording one of the most indubitable instances of the absorption of an abscess which he had ever met with. There was every reason to believe that the removal, even of the cheesy matter, would soon have been effected had not the limb been amputated, since all inflammation about it had wholly passed away.

## THE GREAT NORTHERN HOSPITAL.

### POISONING BY ACETATE OF LEAD.

A case was admitted last week, under Dr. Leared's care, in which self-destruction by acetate of lead was attempted. A healthy young man took before breakfast two pennyworth of the salt in half a tumbler of water. He was careful to swallow the portion remaining undissolved. In about a quarter of an hour he vomited. He had now some epigastric and frontal pain, severe abdominal pain ensued, and in about three quarters of an hour from the time of swallowing the acetate he was purged once freely. Two hours subsequently he was brought to the Hospital. The only thing he then complained of was the abdominal pain. The pulse presented nothing remarkable. He was immediately given sulphate of zinc as an emetic. The next day sulphate of magnesia was given, as the bowels were constipated. He was discharged well on the day following.

It was ascertained from the chemist from whom it was procured that one ounce of acetate of lead is sold by him for twopence.

Dr. Leared remarked that the case was interesting, as affording additional evidence of the comparative harmlessness of the acetate of lead, although popularly regarded as an active poison; also the purgative action of an astringent salt, owing to the largeness of the dose, was instructive.

### No. 229.—A PLEA FOR THE RED PETTICOAT.

A friend, who is both mesmerist and transcendentalist, maintains that this article of dress, now so fashionable, is suggested by a physiological principle, lying deep in the female mind, although the possessor is unconscious of it, that the wearing of it indicates a true and innate idea of modesty, as the following extract from an old author shows; from which also we learn that clairvoyance existed long before the time of Mesmer. As so much has of late been said on ladies' dress, we are happy in placing the subject in a right point of view:—"Père Lebrun, in his 'Critical History of Superstitious Practices,' cites a letter of the celebrated Huygens to the Abbé Marsenne, dated November 26, 1640, in which it is related that they had a prisoner at Antwerp who could see through all kinds of stuff and clothing, provided only the same were not red. Once came several charitable women to him in the prison, with a view to comfort him in his ill fortune; but in the midst of their Christian-like discourse he began to laugh, and being asked of the reason of this unmannerliness, made answer without shame, 'Because one of you hath no shift on.' Now, if this virtuous woman had by chance had on a red petticoat, she would not have been thus put out of countenance."

SATURDAY, MARCH 20.

### TRUE AND FALSE CHARITY.

In the year 1840 a report was presented to both Houses of Parliament by Mr. Fletcher, Secretary to the Commission of Inquiry into the Condition of the Handloom Weavers. This report contains a great deal of information upon the industrial, physical, pecuniary, and moral condition of the ribbon weavers of the midland districts of England, with some conclusions which apply not only to weavers, but to the working classes generally throughout the country. The remarks of Mr. Fletcher upon the difficulty of distributing charity funds without producing mischief through the too-wide anticipation of their benefits, are so strongly confirmatory of the arguments we have advanced in favour of a reform in the existing system of our Medical Charities, that we quote one paragraph which appears peculiarly apposite:—

"When it is borne in mind that every exertion of industry or of providence checked, by the removal of the stimulus of self-interest or self-preservation, is a dead loss to society, it will certainly appear difficult to devise a scheme by which to administer, without incurring much of such loss, large funds which must be applied in gifts to those who can make out the best case as objects of *pity*. It appears exceedingly invidious to attack institutions to the benefits of which the poorer classes have an undoubted right, which the trustees faithfully administer with gratification to themselves, and the claims to which the freemen esteem one of their most valuable rights. But, when it is put upon its best footing, the present system is, to a great extent, only a mischievous *lottery*, the candidates being more numerous than the prizes, and relying so much and to such an extent on the prospect of enjoying somewhat of these common funds, that the balance of misery induced over the good rendered by them is considered by some of the inhabitants to be most decisive. Whether such funds, with legislative sanction, might not be so administered, equally for the benefit of the poorer classes, and yet so as to invigorate rather than to benumb the fundamental virtues of civil life, is worthy of the deepest consideration. The Self-supporting Dispensary embodies a principle capable of great and beneficial extension. As uniting an exercise of charity with an encouragement to industry and providence, it demands especial notice, and is worthy of general imitation."

The following extract from one of the reports of the Coventry Self-supporting Dispensary affords a good summary of the principal advantages of these Institutions:—

"They render Medical aid more accessible to the poor than any other kind of Dispensary; and by providing them with Medical advice in the earliest stages of sickness, tend to prevent disease among that class of persons, and to mitigate the numerous evils consequent on delay in the application of efficient remedies.

"The mode of extending Medical relief to the sick poor in these Institutions is more satisfactory to the patients than in any other, as they have the choice of their Medical adviser, and receive his services without any sacrifice of independence, and without the sense of degradation which attends the reception of gratuitous charity.

"In a moral point of view Self-supporting Dispensaries are highly important in assisting the poorer classes to maintain themselves in honest reliance on their own industry, in exciting and encouraging among them habits of prudence, forethought, providence, and mutual assistance, and in thus aiding Friendly Societies, Savings Banks, and all other Institutions calculated to render them permanently independent, and to elevate the feelings, character, and condition of the working community."

All this seems so true, so undeniable, that the wonder is why a system so good in principle, and which has proved so successful in practice in many of our large towns, has not been adopted in the metropolis. It cannot be for the want of a class likely to be benefited by the system, for it is difficult to believe that, if the *shifting* population of London be set aside, there is, or can be, any medium class of poor who should be considered above the resort to parochial aid, and yet unable to enrol themselves as members of a Self-supporting Dispensary. If there be such a class, it has been created by the demoralising influence of indiscriminate charity. Those who would consider resort to the parish a disgrace, are not above accepting relief gratuitously at hospitals or dispensaries. The popular mind should be disabused of this error, and taught that there can be little distinction between parochial relief and that of any purely charitable institution.

But something more than this must be done to inaugurate a reformed system of medical charity in London. The ground, however, is prepared, and it is only necessary to revive a dormant (not an extinct or dissolved) Society, to carry out this most desirable object. We have before us the General Report for the year 1850 of the "London Society embodied to promote the establishment of Provident Dispensaries." Probably many of our readers never heard of this Society,

yet it contains in its list of officers men of the greatest weight and influence in the Profession. Sir Benjamin Brodie and Sir Charles Locock are among its Vice-Presidents. Mr. Bacot, Mr. Bowman, Mr. Blagden, Sir James Clark, Dr. Conolly, Dr. Copland, Mr. Ferguson, Dr. Little, Mr. Partridge, Mr. Probert, Mr. Skey, Dr. Sharpey, Dr. Tweedie, Mr. Toynbee, Dr. Forbes Winslow, and many other well-known London names appear on the list of Council. Edinburgh and Dublin are also represented by good men, and the provinces send the Bullars, of Southampton; Cowan, of Reading; Martin, of Reigate; Paget, of Leicester; Robertson, of Northampton; in addition to gentlemen who have assisted in working the system at Derby, Burton-on-Trent, Coventry, and other towns. Sir John Forbes, Dr. Watson, Dr. Benoe Jones, Dr. Todd, and others also appear as expressing their approval of the principle of the Society.

Yet this Society, so well supported by eminent names, has done nothing beyond issuing its Report for 1850. If we ask the reason why, one gentleman says, "It was not supported by the Medical press;" another that "It was opposed by the General Practitioners, who were misled as to the objects of the Society." There is probably some truth in both of these opinions, but we believe the principal reason of the temporary failure—we say temporary, because we deem the ultimate success to be certain—is to be found in the fact that no one person took an active energetic personal interest in the success of the Society's objects. Mr. Smith, the benevolent originator of the scheme, could not leave Southam for London. The Secretary, it appears, was not adapted for his post, and eight years have been lost. But it is "never too late to mend." Let the Society be resuscitated—reorganised if necessary—and let us have the bearings of these Provident Self-supporting Dispensaries upon the poor and the Profession thoroughly discussed.

## THE WEEK.

THE "battle of the bills" is to be fought again this Session in the House of Commons, if we are to trust to notices given on Tuesday night by Mr. Cowper and Lord Elcho. Mr. Cowper merely announced his intention of introducing a Bill; Lord Elcho got the start of him, however, and actually had his Bill read a first time. He is reported to have said that it was identical with that introduced by him last Session; but it is understood that he is not likely to press for more than one uniform general examination by a Government board, giving a legal right to practise throughout the empire, and a State registration to enable the public to distinguish legal from illegal practitioners, the present Universities and Corporations being left to compete for candidates for diplomas, which would become purely honorary. Mr. Cowper's Bill will probably be a modification of that of Mr. Headlam. If both be persevered with, it is quite clear that neither can succeed, and unless the Universities and Corporations can agree to adopt some middle course, the present Session of Parliament will afford another illustration of the difference of Doctors, and the indifference of Government. If Lord Elcho's simple measure, embodying uniform qualification, unrestricted right to practise, and State registration, cannot be accepted by the Corporations, surely both parties might unite in obtaining the ROYAL COMMISSION of inquiry we have so frequently insisted on as a necessary preliminary to satisfactory legislation.

Some weeks ago we announced that the College of Surgeons contemplated a material reduction in the number of lectures to be attended by candidates for the College diploma. The proposal has been submitted to the College of Physicians, and received the marked approval of this learned body. We

are not at liberty to mention the precise changes which are likely to be adopted, as they are understood to be under the consideration of the Colleges of Dublin and Edinburgh; but we may state that while it is proposed that not less than four years shall be devoted to professional study, only two years and a half will be occupied by a stated curriculum. It is probable that the number of *courses* of lectures to be attended will be diminished, and that the courses will be shorter. For instance, only one course of Physiology is to be demanded, and that a much shorter one than the 100 to 130 lectures to which it has extended in some schools. Two courses of Anatomy will be required, but only one of Surgery. These are the leading changes, the object evidently being to enable the student to devote more time to Hospital practice and Dissection, and to give him more opportunity for the best of all education—self-training. There will be two examinations; one anatomical at the end of the second winter session, the other surgical, at the close of the fourth year's study. Both examinations will be made far more practical than at present by the use of preparations, and requiring actual dissections and operations on the subject. It is not desirable to be more explicit until the details are finally decided upon, but we have said enough to show that the change is one quite in accordance with the spirit of the age, and that it is one likely to have a very beneficial effect upon students, teaching them to think, work for, and depend upon themselves; to discourage the system of cramming, and rather to test a man's knowledge, than be satisfied with certificates that he has paid for the opportunity of acquiring it.

The local authorities in France, in case of breaking out of epidemic disease, have the power of very peremptorily demanding the services of the Medical Practitioners of the locality, irrespective of the detriment this may prove to their private practice. It will hardly be believed that the local tribunals have declared that such services need not be remunerated when called for on public emergency. However, Dr. Andreux, doubting whether the law of such a decision was much better than its honesty, having been summoned by the Mayor of Bar-le-Duc to give his services during the prevalence of cholera, and being refused payment, appealed to the Court of Cassation. This, the supreme court of the realm, has decided that no man must be called upon to sacrifice his time, labour, or industry, even in the case of public calamities, without suitable remuneration; and that the mere fact of applying for his aid implies the intention of paying for it. The decision of the inferior court was therefore reversed.

Dr. Thompson makes the following important observations in his last monthly report on the health and climate of Marylebone. "During the month, 47 inhabited stables have been improved in their sanitary condition: 16 of these have been supplied with new closets, of which they were previously destitute; 24 have been drained, most of them having no means whatever of carrying off the fluid soil. Such stables have usually a cesspool in the stall in which the soil stands, evaporates, escapes by overflow—as the case may be—or sinks into the interstices of the pavement on which the horses stand. The result of this horrible arrangement is, that the sulphates of the soil become deoxidized by the animal matter; sulphuretted hydrogen—one of the most poisonous of gases—is generated, and carrying with it other exhalations, mixes with the air breathed by the poor animals, and makes its way into the apartments above, occupied by the still more unfortunate servants. Stables which are painted, speedily have the surface of the pigment completed blackened by the union of the sulphur of the gas with the metal of the

white lead. This unhealthy condition is sufficient to account for the fatal form which scarlatina, measles, and hooping-cough assume when they attack children inhabiting Mews. It is to similar emanations from sewage soaking into the lower levels that we must ascribe much of the aggravation of epidemics of diarrhoea and cholera, which has been demonstrated to be in the direct ratio of proximity to the Thames. Sulphuretted hydrogen, derived from imperfect and untrapped drains in areas and cellars, may be observed to attack the painted fronts of many houses in this parish where oil paint has been employed."

There is a grievance to which Medical practitioners are subjected under the late Registration Act, and of which they loudly and justly complain. They are compelled under a penalty to transmit to the Registrar of the district a certificate of every death occurring in their practice; and in this document, besides a variety of other details, they must state their *professional opinion* as to the cause of death in each case. This necessarily involves much trouble, as well as responsibility, and we do not see on what plea the Legislature can justify its right to demand services for which it gives no remuneration, and at the same time punish Medical men for non-performance of such service. If the information conveyed in these certificates be of any public benefit, it is surely worth paying for; and if on the other hand it be of no benefit, why subject the Profession to this trouble? Indeed, with no greater degree of injustice, in so far as involves principle, might all the Parochial Registrars throughout the country be compelled by an act of the Legislature to perform gratuitously the duties devolving on them in connexion with the Registration Act. There has not been any general movement in the Profession to obtain redress, but in the meantime the initiative has been taken by the Medical practitioners of Montrose, who have forwarded to Parliament a petition, of which the following is a copy:—

"Unto the Honourable the Commons of Great Britain and Ireland in Parliament assembled, the petition of the undersigned Medical Practitioners in Montrose,

"Humbly sheweth,—That whereas by an Act passed in the seventeenth and eighteenth years of the reign of her present Majesty, intituled 'An Act to provide for the better Registration of Births, Deaths, and Marriages in Scotland,' Medical Practitioners 'who shall have been in attendance during the last illness, and until the death of any person, shall, within fourteen days after the death of such person, and under a penalty not exceeding forty shillings in case of failure, transmit to the Registrar a certificate of such death.' And no compensation is provided by the Act for such professional service; and whereas such unremunerated service under such penalty is felt by your petitioners to be both unjust and oppressive,

"May it therefore please your Honourable House to repeal so much of the said Act as compulsorily exacts such service from Medical Practitioners, or to enact that they shall henceforth be entitled to receive a just and adequate remuneration for the same. And your petitioners will ever pray.

(Signed)

"HENRY HOILE, M.R.C.S.

S. LAWRENCE, M.D., L.R.C.S. Ed.  
JOHN BURNES, M.D.  
A. M. OFFICER, M.D.  
JAMES C. HOWDEN, M.D.  
JOHN A. ROSS, L.R.C.S. Ed.  
Geo. STEELE, M.D., L.R.C.S. Ed."

The matter is one well worthy of attention.

The Medical Court appointments, consequent on the death of Mr. Travers, had not been completed at the time of going to press. It is supposed that three will be made: the Serjeant-Surgeon, a Surgeon Extraordinary to the Queen, and

a Surgeon Extraordinary to Prince Albert. The names of several gentlemen have been freely mentioned, but as nothing has yet been decided upon we think it better not to allude to the matter further at present.

Mr. Griffin has this day published his pamphlet upon the grievances of the Poor-law Medical officers. He commences his task by an energetic appeal to the Members of the two Houses of Parliament, showing the gross injustice with which the Poor-law Medical service has been uniformly treated by the local Guardians and by the Poor-law Board. He has also printed his draft of an Act for the better regulation of Medical relief to the poorer classes in England and Wales, and in a copious commentary he explains the arguments and the facts on which the different sections of the proposed Act have been founded. In connexion with this portion of the pamphlet is a scheme for the better performance of vaccination throughout the country, imposing penalties on parents or guardians for neglecting the operation, and defining adequate compensation to Medical officers who are engaged as vaccinators. There is also a plan for the establishment of a Superannuation Fund for the benefit of those Poor-law Medical officers who have been disabled from their duties by age or disease. Then follow some articles from the General Consolidated Order, and other orders of the Poor-law Board relating to the duties of Medical officers; and afterwards numerous extracts from the official circulars of the Poor-law Board, referring to matters connected with the Poor-law Medical service. The pamphlet concludes with a list of subscribers to Mr. Griffin's Fund from the Poor-law Unions; and some idea may be formed of the magnitude of the existing evils, and of the general desire for redress, by the fact that the list of Medical officers fills no less than fifteen closely printed pages! When we consider the tyranny to which this portion of our Medical brethren are subjected, and the wretched salaries which are doled out to them, it is easy to understand the sense of wrong which has caused them to come forward in such numbers, and to add their contributions to the general fund. Some of them, it is true, have been deterred from publishing their names, no doubt from the fear of dismissal at the hands of their vindictive task-masters; and in many cases, therefore, we find them mentioned only as so many Medical officers from such and such a Union; but the great majority boldly came forward with their names and their money in support of the righteous cause. Such an array of names must surely speak trumpet-tongued in favour of speedy redress, more especially when taken in connexion with the pregnant fact, that no less than *seven hundred and forty-four* Medical men have quitted the service of the Poor-law Board during the last three years,—some from dismissal, many from disgust, some actually from disease and death brought on in the discharge of their duties! Such continual changes are, indeed, to be deplored, as Mr. Griffin truly remarks, for the services of Medical officers become more valuable in proportion to the experience which they obtain, while the constant transferring of the sick poor to the hands of new and inexperienced Practitioners must be in the highest degree detrimental to the public interests. We most earnestly beg the attention of the Members of the Legislature to Mr. Griffin's very able address, and to the startling facts and powerful reasons which he adduces. That the Poor-law Commissioners have had committed to them the power of rectifying many of the evils of which the Poor-law Medical officers complain, is most distinctly proved; and as they have, in this respect, most grossly neglected their duty, it becomes the office of the two Houses of Parliament to administer to them, through the President of the Poor-law Board, that wholesome correction which is usually bestowed in our free Constitution

upon political delinquents. Never was a time more opportune than the present for the appearance of Mr. Griffin's pamphlet. The new President of the Poor-law Board has only just entered upon his office, and upon the principle that new brooms sweep clean, we hope that he will lose no time in removing the injustice to the Poor-law Medical officers, to which his predecessors have so long subjected them.

## REVIEWS.

*The Ganglionic Nervous System: its Structure, Functions and Diseases.* By JAMES GEORGE DAVEY, M.D. M.R.C.S. Pp. 309. London: 1868.

THE precise part which the ganglionic system plays in the human body has never yet been determined, nor have its lesions been definitely associated with well-recognised forms of morbid action. It is true that Medical writers of no mean celebrity have from time to time attributed certain forms of disease to derangement of the ganglionic or organic system of nerves, but these views have been mere hypotheses, and have never been supported by pathological investigation. Experiments upon the lower animals, and pathological observations in the human subject have pretty well established the relative functions performed by the brain, the cerebellum, the spinal cord, and the nerves of sensation and motion, but the office of the ganglionic system is still involved in doubt and mystery. The only circumstances which seem to throw any light upon the functions of the ganglionic system are the existence of monsters, which perform certain vital actions, such as circulation and nutrition, although they are without a brain or spinal cord; and experiments similar to that recorded by Dr. Davey, where the heart of a frog continued to pulsate for three hours after the cerebro-spinal structure was annihilated. But it may, we think, fairly be questioned whether such cases prove the direct agency of the sympathetic system, and whether they do not rather belong to the class of phenomena often observed in the lower animals, where an organ or structure continues to exhibit automatic movements although separated from, or even destitute of, any nervous centre. It may be true, indeed, as is urged by Dr. Davey, that in the very lowest classes of animals, as the infusoria, the polypes, and the sponges, there may be a nervous system, and that this system may correspond to the ganglionic; but still we are bound by the evidence of our senses, and we can no more assert the presence of nerves in the fresh-water polype, than we can in the sensitive plant or the water-lily; both of which plants, with many others, present phenomena very similar to those usually effected by nervous agency.

In the above remarks we have embodied the principal questions contained in Dr. Davey's work. His object appears to be to show that the ganglionic nervous system exists in all classes of the animal kingdom, even the lowest, and that it is equal, in the importance of its functions and its derangements, to the cerebro-spinal system.

The pathological portion of the work consists chiefly of papers written and published by the author many years ago; of cases which have occurred to him from time to time in his public and private practice, and which he thinks illustrative of his views; and of quotations from the cases and remarks of other writers.

*A Practical Treatise on the Diseases of Infancy and Childhood.* By T. H. TANNER, M.D., F.L.S.; Licentiate of the College of Physicians; late Physician to the Hospital for Women, &c. &c. Pp. 408. London: 1868.

Dr. Tanner is already favourably known as an author. He now comes before his professional brethren with a new and comprehensive Treatise on the Diseases of Children. A glance at the table of contents will show that the scheme of the book is truly a comprehensive one. It begins with an Essay on the Duration of Life, and the Conduct of Women during Pregnancy; then gives a chapter on the Diagnosis and Prognosis of Infantile Diseases, and the peculiarities of the countenance, gestures, circulation, and so forth; next there comes an entire body of *Materia Medica* and Therapeutics adapted to the period of infancy; then a chapter on Manage-

ment and Education; then, one after another, an account of the various accidents, diseases, and deformities, with their treatment; and, lastly, an Appendix of Formulæ.

Dr. Tanner evidently possesses one essential qualification for authorship. He has been a reader himself; hence his style is clear and intelligible, sometimes even ornate, rising (when the subject admits of it) to something like eloquence, and everywhere enriched with a multiplicity of quotations from authors of the best age of English literature—Bacon, Jeremy Taylor, South, and Addison; to have become familiar with whose writings must ever be considered as one of the most creditable modes in which a young Physician can employ his leisure. Besides, his quotations from the works of his Medical brethren are numerous and varied, and the names of West, Maunsell and Evanson, Underwood, Trousseau and Watson,—in fact, of almost every modern writer of repute, are quoted with due acknowledgments.

Our space does not admit of quotations; but we may state, that an extreme aversion to bloodletting is a characteristic of Dr. Tanner's rules of practice.

Of course the book has some defects; for example, the scheme is far too comprehensive to be carried out in the space allotted; hence many subjects, such as glanders and elephantiasis græcum!! are touched on, although the amount of information conveyed respecting them is necessarily too small to be of much use. Some omissions, too, there are. But these are faults which are generally corrected in a second edition.

We will allude to one more point. Dr. Tanner is a sturdy opponent of bleeding in any form, and for any, or almost any disease. He believes bloodletting is a cause of mortality in croup. He quotes and condemns Dr. West's recommendation of bleeding in pleurisy and pneumonia, even when the symptoms are urgent, and the previous health good; and he will not allow of it in bronchitis, or acute desquamative nephritis. So far so good. It is better never to bleed, than to bleed wrongfully; and a prepossession of this sort is a safe thing for young practitioners, who are not gifted with much power of thought. Nevertheless, Dr. Tanner is even profuse in his recommendations of tartar emetic, than which no drug whatever is more hazardous for children, when administered by unskilful hands. He gives at least a dozen formulæ containing it; besides which prussic acid, lobelia, digitaria, belladonna, and in the case of infants, something like starvation, are recommended in a way which we think would be dangerous to act upon too implicitly. Fancy, for the simple diarrhoea of a sucking infant, the recommendation that it "ought to be taken from the breast for twelve hours or so, until the irritability of the stomach ceases; a few tea-spoonful of plain water or barley-water being given occasionally to quench the thirst." Luckily, however, Nature herself would compel any mother who held a sick infant in her arms, to break through any such medical direction. We may remark, in conclusion, that in the Appendix of Formulæ many of the doses appear large, not to say dangerous. For instance, a grain to a drachm is given as the proper strength of a solution of sulphate of atropine for dilating the pupils of children. This is at least eight times too strong.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### AN EPIDEMIC OF ULCERATIVE OMPHALITIS.

By M. MEYNET.

M. Meynet describes this epidemic as he observed it in the wards of M. Valette at the Charité Hospital, Lyons; and his paper is interesting as showing the marked efficacy of chloride of zinc. It resembled in its characters hospital gangrene more than erysipelas, properly so called. At the commencement the appearances merely consisted in an exaggerated condition of a very ordinary phenomenon, the slight inflammation accompanying the fall of the cord. This inflammation, then, being accompanied by ulceration, cicatrization of the umbilicus was delayed, and soon the symptoms of intense phlegmasia were developed. The umbilical region became of a deep redness, and was surrounded by an enormous, but circumscribed tumefaction. The cutaneous border surrounding the base of the cord became ulcerated and

everted, and the ulcer, getting deeper and wider, was covered with a grey, pultaceous membrane, and generally discharged a thick, purulent, fetid sanies. In proportion as the ravages of the ulceration extended the red circle enlarged, taking on a wine-ley colour, and the tumefaction, more and more voluminous, became hard and resisting. In many cases the red areola was encircled by small, more or less confluent, roundish, dirty-white pustules, containing turbid or purulent serosity. Beneath, the dermis presented small, round, depressed ulcerations. Sometimes the erysipelatous circle was covered by enormous sanguinolent phlyctenæ, and when these broke the ulceration soon invaded the exposed dermis. The general health was not always affected at the commencement; but very soon the child refused to suck, cried continually, wasted away, and was sometimes carried off within thirty-six or forty-eight hours. Sometimes the progress of the disease was slower, but very often even then fatal.

In other cases, the disease commenced at once by ulceration, which soon committed great ravages, either propagating itself along the umbilical vessels, or over the abdominal parietes. Its form was irregular, and its surface was either of a violet grey, exhaling an odour of gangrene, or was covered by a soft adherent false membrane, as in hospital gangrene. In these cases the surrounding livid circle was less circumscribed, there was less tumefaction, and the pustular eruption was often absent. The general symptoms also came on sooner, sometimes preceding the ulceration; the infant soon passing from a state of great agitation into fatal collapse.

The various remedies usual in such cases, including the actual cautery, were tried in vain, when M. Valette had recourse to chloride of zinc paste, spread on linen. This was completely applied to the ulcerated surface, and the result was, that in place of an invading ulcer, a limited and clean wound, with tendency to cicatrization, was produced. Whenever the disease was thus treated at an early stage, and the caustic could be applied to all parts of the ulcerated surface, it never failed in its effects, one application usually sufficing.—*Bull. de Thérap.* tom. liii. p. 226.

#### ON CATAPLASMS AND CALORIC IN CHRONIC ARTHRITIS.

By Professor TROUSSEAU.

For a very long period M. Trousseau has derived the greatest advantage from the application of cataplasms to joints suffering from chronic inflammation; cataplasms, however, prepared in the following way: When the knee or other large joint is the one in question, 3lb. (troy) of bread are boiled down to a consistency admitting of its due application and retention on the part. When the bread has nearly reached such consistency 20 or 30 drachms of spirit of camphor are to be added, and the boiling continued awhile. The poultice thus prepared is to be put on a cloth, and the following mixture is to be spread over its surface, viz., powdered camphor, extract of belladonna,  $\text{aa}$  150 grs., extract of opium 75 grs., alcohol q.s. to render the extract sufficiently soft. Finally, to prevent the cataplasm becoming dried at its edges, these are covered by a slight coating of glycerine. This poultice is an expensive one at first, but then it is to continue applied for eight or nine days, during which time it retains its moisture, and does not undergo fermentation. The poultice is surrounded by a large piece of oiled silk, and by flannel bandages. The case which gave occasion to this description was a serious example of puerperal arthritis, in which leeches and the ordinary cataplasms had failed to give relief. From the time this other form of poultice was applied, amelioration became progressive, and after the third application, i. e. twenty-five days of treatment, the limb, before inflexible, could be moved, and the pain had nearly gone. For the next fortnight, linseed poultices, on which a mixture of belladonna and opium was spread, were applied; and then, as the condition of the joint seemed stationary, bags of sand, heated almost to burning, were laid on the knee. After two days' application of the hot sand, which was repeated twice in the twenty-four hours, the improvement again became considerable. In M. Trousseau's opinion, some of the mineral waters which are of such remarkable efficacy in chronic phlegmasias, owe this rather to their excess of caloric than to their chemical composition. By means of bags of hot sand, hydatrothes, which have resisted the usual treatment, sometimes disappear with remarkable rapidity.—*Gaz. des Hép.* 1857. No. 104.

## EXCERPTA MINORA.

**Bromide of Potassium in Spermatorrhœa and Satyriasis.**—M. Binet strongly recommends this substance, which may either be given in powder or solution, according to the following formulæ: *R. Brom. pot. xv. to xxx. gr., sacchar. gr. c.; divide in xii.; cap. i. 2dis. horis. R. Brom. pot. 3v. aq. 3lxxv.* Dose, a table-spoonful.—*Presse Belge*, No. 8.

**Chloroform in Vomiting in Consumption.**—Dr. Baron calls attention to the advantage he has derived from the administration of small doses of chloroform in the vomiting which so frequently accompanies the cough in phthisis. In all the patients he has tried the plan, amelioration has rapidly ensued. He gives 12 drops in a gummy julep in the course of the twenty-four hours, and in some cases still smaller doses relieve. He is about to try the same treatment in the vomiting of pertussis and pregnancy.—*Gazette Méd.* No. 7.

**Tartar Emetic in Bright's Disease.**—M. Legroux, of the Beaujon, has derived great benefit from the employment of tartar emetic in sufficient doses to produce frequent vomiting and purging, giving the patient when much exhausted by the treatment a few days' interval of rest. He attributes some of the advantage he has derived to the simultaneous employment of the *spirea ulmaria*, as a tisane, this being a valuable diuretic, though not always a faithful one.—*Gaz. des Hôp.* 1857, No. 97.

**Percussion at the posterior part of the Thorax.**—When we percuss perpendicularly to the axis of the body over the supra-spinal fossæ, or between the scapulæ, we may always observe, even in the healthiest persons, a certain amount of resistance or dullness, situated deeply, and due to the fact that the anterior portion of the first ribs and the clavicle are in front of the shock, and are only separated from the posterior surface by a very thin layer of lung. To remedy this, M. Piorry places his plessimeter and percusses in such a manner that the shock is sent in the direction of the longest diameter of the lung, i.e. vertically. By this plan doubtful pulmonary indurations may be often detected.—*Ibid.* No. 151.

**Myocarditis as the Cause of Rupture and partial Aneurism of the Heart.**—M. Mercier, in an interesting essay giving an account of ten cases of partial aneurism of the heart which have come under his own notice, and from the consideration of these and cases published by other observers, comes to the following conclusions:—1. That almost all the spontaneous perforations of the heart are the results of a circumscribed myocarditis, which has continued its progress unchecked. 2. The fibrous transformation of the muscular tissue of the heart is produced by the resolution of this inflammation, when it has become arrested at a certain point. 3. Dilatation is brought about by the pressure of the blood on this tissue, which has lost its contractility, and has become elastic like all fibrous tissues.—*Gaz. Méd.* 1857, No. 40.

**Chlorine in Dissection Wounds.**—M. Nonat states that since 1830 he has repeatedly treated even serious cases of dissection wounds with the best effect by means of solution of chlorine. If the wound is recent, it should be at once freely washed with water, and if it is large and bleeding such washing will usually suffice; but when it is narrow the washing is not enough, and the chlorinated water must be also employed. When the wound even dates several days, is painful and inflamed, and is accompanied by inflamed absorbents and general symptoms, the chlorine will give relief, providing symptoms of purulent infection have not set in. Some inspirations of chlorine may be usefully conjoined.—*Gaz. des Hôp.* 1857, No. 97.

**Condition of the Uterus in Hæmorrhage.**—M. Paul Dubois observes that the opinion has gained admission into almost all works on midwifery that in hæmorrhage the uterus is soft and flaccid, and its walls are not distinguishable. Without denying the possibility of this being the case, he has never himself observed it. It is very rare for the uterus to contain much blood, even in the case of internal hæmorrhage. It is, in fact, a contractile cavity, and the blood passes into the vagina, where it accumulates, because the vagina does not possess the contractility of the uterus. Examination always shows the presence of a large quantity of blood in the vagina, the uterus containing very little. Internal uterine hæmorrhage is a very rare occurrence, as this organ does not become distended after delivery, the blood being propelled into the vagina.—*Ibid.* No. 102.

## GENERAL CORRESPONDENCE.

## DR. HENRY SILVESTER'S NEW METHOD OF TREATING APNŒA.

[To the Editor of the Medical Times and Gazette.]

SIR,—Your correspondent in your Journal of February 12, 1858, appears to have overlooked the drift of my last paper on artificial respiration, which you did me the favour to insert on February 6, 1858, and has expatiated on a matter of detail which I had purposely omitted, namely the management of the tongue in cases of apnœa.

The object of my last paper was to give the results of three kinds of experiments on the dead body, which proved, 1stly, that when there was no obstruction to the entrance of air into the trachea, the *Postural Method* did not produce a greater amount of respiration than was produced by simple pressure on the front of the chest by the hand of the operator. Also that neither by the postural method nor by simple compression of the chest was the actual capacity of the thorax at all enlarged. 2ndly, that the actual capacity of the thorax was greatly enlarged, and that a large quantity of air was immediately inspired by drawing up the arms of the subject by the side of its head so as to raise the ribs by means of the pectorals, and was then expired by pressing the arms down again on the sides of the chest, as I have before fully explained. The quantity of air respired according to my experiments on the dead body appears to be about ten times greater in my method than in the postural method.

It is, of course, of consequence to get as much air into the lungs as possible; because there can be but little doubt that fresh air is the proper stimulant to the respiratory efforts, just in the same way that light is to the eye and sound to the ear, but acting more entirely by reflex action.

I now pass on to make a few remarks on the management of the tongue in connexion with artificial respiration. In cases of asphyxia the tongue is usually swollen, and falls back into the throat, so as to act as a plug to the pharynx, and a valvular cover to the otherwise patulous orifice of the larynx. This perhaps tends to prevent the entrance of foreign bodies into the lungs.

In the postural method, when the body is turned on the face, no doubt the tendency is to throw the tongue forwards. This, however, is of little consequence, so far as respiration is concerned; for the very compression of the chest by the weight of the body itself forces out the air from the lungs, and so lifts up the valvular covering of the larynx, so that the tongue does not offer any serious obstacle to expiration when that is induced by compression of the thorax, by whatever means employed.

With regard to inspiration, in the pronation and supination method, the moment the patient is rolled "on the side, and a little beyond," the tongue falls back again into the throat, and its "semilifeless relaxed tissue" covers securely the orifice of the glottis, and its accurate closure is probably further insured by the suction generated by the return of the thoracic parietes to their natural level; so that the greater the previous compression of the chest, the more firmly is the tongue pressed down as a plug into the throat.

The expedient which I recommend for adoption is as simple as it is efficacious. It raises and draws forwards the patulous orifice of the larynx, so that nothing intervenes between it and the natural channel of air through the nose. It prevents entirely the tongue falling into the throat, whilst the exact extent the windpipe is put on the stretch is clearly indicated. The pharynx also is sufficiently opened to allow of the removal of liquids, etc., from the mouth, nose, pharynx, etc., if these have not been entirely displaced by previous suitable treatment.

The tongue is to be used to regulate the position of the larynx. The tongue having been drawn forwards, and protruded beyond the teeth, the lower jaw is to be gently raised, so that the teeth may hold the tongue in the required position. Should it be necessary, the tongue may be so retained by passing a handkerchief under the chin, and fastening it over the head.

I am, &c.

HENRY R. SILVESTER, B.A. M.D., Lond.

High-street, Clapham, Feb. 23, 1858.

## BLEEDING IN ARMY MEDICAL PRACTICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your issue of last week appears a letter bearing the signature "W. O. Markham," containing the usual misapprehensions concerning the Medical Department of the Army, and their professional practice.

It is not much the custom of the service to rush into print, either to puff themselves into notice, or even to correct the frequent mis-statements that have appeared from time to time in the columns of the public press since the Crimean campaign; but I will step out of the usual course on this occasion to rescue the service from the unjust insinuations contained in the second portion of the letter referred to, and point out to that gentleman what he might have easily ascertained by simply asking one of the Medical Officers of the Guards quartered in the metropolis, instead of assuming, as he appears to have done, "that the practice of large or indiscriminate bleedings in inflammation still exists in the army."

It may perhaps be some information to him to know that the Medical Officers of the Army rather took the initiative in the abandonment of large and frequent bleeding in inflammation, and that it was a retired army-surgeon, Dr. Dickson, who was one of the first to point out to the Profession, in a pamphlet published in 1843, the injurious excess to which this practice had been carried in civil life.

I happen to be just now in a somewhat favourable position to answer Mr. Markham's queries concerning Army Medical practice in general, and the practice to which he refers in particular. Having recently visited a large number of the Military Hospitals in England, I can assure him, his fears and surmises on this head are utterly groundless, notwithstanding the orthodox case of the magnificent Guardaman; and I have no doubt the Medical Officers of the Guards will similarly relieve his mind on this point.

The Medical Officers of the Army, having received their Professional education at the very same schools and colleges as their brethren in civil practice, and being, so far as I am aware, unrestrained in the adoption of whatever practice is most conducive to the welfare of the sick entrusted to their care, treat them pretty much in the same manner, and according to the same principles as their black-coated *cofrères*. If there is anything at all peculiar in Army Medical practice, it is the absence of quackery in every form.

It is not my intention to enter upon the disputed question of the total abandonment of bleeding in inflammation. I believe there are few professional men of any eminence or experience who do not admit the occasional necessity of the practice, at the same time that they condemn its incautious use, and denounce its abuse. Such I know to be the sentiments of a large proportion of Army Medical Officers.

I am, &amp;c. JAMES MOUNT.

Junior United Service Club.

## LEUCORRHOEAL AND GONORRHOEAL OPHTHALMIA.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having paid much attention to the subject of infantile leucorrhoea, both in a surgical and medico-legal point of view, and my name having been mentioned in connexion with some cases of this description in your Hospital Reports in the last number of your Journal, allow me to observe thereon.

The first two cases presented in sisters aged 6 and 4 years, now under the care of Mr. Critchett, at Moorfields Hospital; and here I may observe *in limine* that in reviewing the opinions alluded to in the paper in question, I know not that I am differing in the slightest degree from Mr. Critchett or Mr. Hutchinson; I am only questioning opinions and statements put forward in your Report. These children had some purulent ophthalmia, and their cases were set down as cases of true gonorrhoea, because the inflammation of the genitals which co-existed "was more acute than is generally seen in the bastard diseases of infants;" and because "the mother stated that a lodger who slept in the same room as the [elder] girl was known to have 'the disease,' and she feared the child had caught it by using a soiled cloth;"

the younger child, it is said, "contracted the disease from her sister, as they slept together, and were much exposed." The writer then goes on to comment upon leucorrhoea, and says: "We quote the case chiefly because it shows how liable young children having true gonorrhoea are to have the eyes infected. It is well known that the spurious disease often exists for months together; that it is common among the most neglected children, and yet how almost never do we find the eye suffer! This is doubtless because the discharge in these cases is non-contagious, and we have in the circumstance a means of diagnosis which will occasionally be very useful."

Now, Sir, not only is the foregoing not fact, but it is a most dangerous doctrine, calculated to mislead practitioners, and likely to be attended with gross injustice to the community.

It is not true that in the infant or young girl gonorrhoea causes a greater amount of inflammation of the genitals than leucorrhoea; on the contrary, the very reverse occurs, so much so that in some cases sloughing and death has followed.

There is no warrant whatever, either in law or common sense, for believing that the first child had been infected.

It is well known that true gonorrhoea often exists for months together; that it is common among the most neglected and filthy adults, and yet how seldom do we find the eye suffer; but the eyes do suffer from contact with leucorrhoeal matter, as I have already shown in your Journal in January last year. I have shown that the matter in leucorrhoea is *highly contagious*, infecting the eyes and male genitals, therefore what is stated about its being "non-specific" is contradicted by the weight of evidence.

In cases of rape the detection of spermatozoa in the child's vulva will be unanswerable, but it must be recollected that in those cases to which I have directed attention, and in which your reporter very graphically says, "Not a few innocent men, the victims of circumstantial evidence and of mistaken diagnosis, have undoubtedly been sentenced to punishment for abominable offences of which they knew nothing;" the accusation is never made for many days, and often not for weeks after the alleged date of the offence.

Your reporter relates the particulars of Mr. Hutchinson's case, where the prisoner was sentenced to two years' hard labour, and in which there was no circumstantial evidence against the prisoner, except that he had gonorrhoea, but because a druggist, a "druggist" first, and then an experienced surgeon, stated that the child had "the disease;" so far as I can glean from the statement afforded in your last number, I cannot see any reason to find the prisoner guilty; and certain I am, that had Cooper or Lawrence examined the case, they would have come to a different conclusion. Notwithstanding all that has been written upon the subject, many eminent Medical men are still of opinion, that "innocent men, the victims of circumstantial evidence and mistaken diagnosis," are sentenced annually in our courts of law. Not three months ago a man was tried for murder preceded by a rape, said to be committed on a girl ten years of age, and was sentenced to penal servitude for life; yet the opinion of half a dozen of the highest authorities in the land was that the child was not raped at all, but died of "*noma pudendi*." Here, in Ireland, in one of our southern counties, at the present assizes, a man was found guilty because one child has leucorrhoea and another purulent ophthalmia, both of six weeks' duration prior to the accusation.

I am, &amp;c.

W. WILDS.

## PERINEO-PLASTIC SURGERY.—PROLAPSUS UTERI.

[To the Editor of the Medical Times and Gazette.]

SIR,—With the view of deciding an important Surgical question you some time ago placed the *Medical Times and Gazette* at the disposal of all who might have anything to communicate on Perineo-Plastic Surgery. My papers I intended as a contribution or furtherance of the best objects of Medical journalism; certainly not to decide on rival claims to a mere invention. The Profession, of course, is far more concerned about the veracity and soundness of the statements and arguments of your contributors on other grounds—

thus in my sketch of the history of the subject I did my best to be entirely correct. A glance will show that the claim to originality is not with Mr. Brown, but it does not follow that Mr. Brown was acquainted with the history of the operation before he adopted it, and it was never my object to show that he was. In fact, he affirms he never till lately heard of Fricke and Geddings, which is quite sufficient. If he had not devoted a considerable part of his book to a "Surgical History" of the subject, no one would have thought twice about the matter; and whilst it can in fairness be asserted that it is chiefly owing to his numerous and highly interesting reports that the perineal operation can take a leading place in the surgical catalogue, and that the ingenuity, skill, and dexterity distinguishing his performance of it cannot be surpassed, Mr. Brown can surely leave Caesar in quiet possession of all which belongs to him.

In common justice it is right to say thus much, and it was not my purpose to say more. However, the concluding paragraphs of his letter in your last impression oblige me to express my regret at finding that Mr. Brown is still too susceptible and too hasty. A too hurried compliance with your wish to have a summary of his experience, led to a controversy of the most painful character. An imperfectly considered claim to originality led to the discovery that he had no claim of the kind whatever. A similar fault led to the omission of the names of Fricke and Geddings, and of course also of the least allusion to their operations in his chapter on the "History of the Subject." Yet Fricke's name appears in every systematic work, and Geddings's cases in Braithwaite.

The Profession are waiting for the Statistical Summary you have been all along so properly anxious to give them. This is impossible, unless Mr. Brown can or will accord a little more time and pains to the subject. In round numbers he, in the communication which gave rise to the controversy I allude to, states his cases as 75, all successful. He was reminded of the case of failure rejected at our Hospital, that of Julia L., and now he mentions three more. Failure in four cases out of 75 instances of success in relieving the most distressing and intractable malady conceivable, can dim the lustre of no man's reputation. But is this really all? Is it too much to ask Mr. Brown to give us some reliable assurance that he has been reasonably scrupulous? Again, he says in this same letter of last week, "Having observed the effect of my operation in keeping the womb *in situ*, etc." If he means keeping the womb in its normal situation, I must remind him that no perineal procedure will keep the womb *in situ*. I am quite sure this is his opinion too. He means, keep the womb from falling out of the vagina. One great advantage of candour in physic is the saving to others mistakes in pioneering. What unestablished operation in this world succeeded 75 times without a failure, or without suggesting some necessary precaution not at first apparent? Besides, the practitioner has a right to demand reasonable precision on the part of those voluntarily addressing him on matters of practice, especially when these happen to be unusual, difficult, or undecided; and I only refer to the misuse of the term successful as offering an additional excuse for expressing a hope that he will, in his final summation of cases, not allow the pressure of his vocation to betray him into a style inconsistent with the maintenance of that confidence to which his well known energy in this branch of our art, I believe, should entitle him.

I am, &c.

HENRY SAVAGE.

3, Gloucester-place.

P.S.—Is Mr. Brown quite sure he takes "as much away as I do?" because, if so, my experience justifies me in advising him to look out for failures in every case where he removes the deep sutures on the evening of the second day.

## DR. BROWN-SEQUARD ON EPILEPSY.

[To the Editor of the Medical Times and Gazette.]

SIR,—In the review of my work on Epilepsy, in your last Number, it is said that the end of the work does not agree with the beginning; and the reviewer gives it to be understood that in one part I have tried to show that the seat of the disease is in the spinal cord; and in another, that this seat is in the encephalon. Neither of these views is mine. I have tried to show that the disease may originate from almost any

part of the nervous system, and that its organic cause may be as well in the spinal cord as in a peripheral nerve, or in the brain. Instead of supposing that the seat of the disease is in the spinal cord, I have related many facts to prove that, even when the spinal cord is the only organ where an alteration is found, the seat of the affection may have been elsewhere. I have tried to show that, whatever part of the nervous centres be first altered in epilepsy, the symptoms may be the same; while, on the contrary, they may vary, although the primitive alteration in different cases may be at the very same place.

As the seat of the disease is, according to what I have attempted to prove, in the part of the cerebro-spinal axis, which gives origin to the nerves first affected; and as there are great differences in this respect, it follows that the seat of this affection is variable. But daily observation, in man as well as in my epileptic animals, shows, that almost always the first parts affected are animated by nerves which come from the base of the encephalon, and from the upper part of the spinal cord. The conclusion to be drawn from these observations is, therefore, that the seat of epilepsy is most frequently in the named parts of the encephalon and spinal cord.

I am, &c.

E. BROWN-SEQUARD.

Paris, March 15.

## CHLORODYNE.

[To the Editor of the Medical Times and Gazette.]

SIR,—I observe in your Number of Saturday last a letter from Mr. Davenport, regarding my analysis of a preparation called "chlorodyne." This compound is represented by the manufacturer to be a perchlorate of a new alkaloid, which is said to have been discovered by Dr. J. Collis Brown while serving her Majesty in India.

Some time ago a bottle of this chlorodyne was placed in my hands for examination. I submitted it to the usual processes adopted by modern investigators for isolating the constituents of organic mixtures, and to my great surprise I obtained (about 50 per cent. of chloroform, besides distinct evidences of prussic acid. It really appeared to me very strange that a "perchlorate of a new alkaloid" should yield such constituents; and this circumstance led me to examine it more minutely. The examination I made of it was a very general one. I submitted a fluid ounce of the chlorodyne to very gentle distillation by a water-bath, and obtained a colourless distillate measuring half a fluid ounce. This distillate separated into two strata, the upper and smaller one being an aqueous solution of prussic acid, the lower and larger one chloroform. I next examined the dark-coloured residue. When a portion of this was heated strongly it intumesced very violently, indicating perchloric acid. To determine the presence of this acid with certainty I mixed with a portion of the residue (after all the chloroform had been separated) a small quantity of pure alcoholic potassa evaporated to dryness and ignited. By this means I combined the perchloric acid with the potassa, and formed perchlorate of potash. By igniting this the oxygen of the perchloric acid was evolved, and burnt off the organic matter in a few seconds. The white residue when tested with nitrate of silver was found to consist of chloride of potassium. In this manner I proved perchloric acid to be one of the constituents of chlorodyne. On further examination of the dark-coloured residue I recognised the odour of peppermint, the pungent and unmistakable taste of capsicum; and by other tests I recognised liquorice, with which there might have been a little treacle. In this residue I moreover recognised the presence of a basic substance, which in its properties bore a remarkable resemblance to morphia. To have investigated the base I isolated fully, I should have required at least half a dozen bottles—an expense I did not think it worth while to incur, especially after finding the chief constituent of chlorodyne to be chloroform.

Mr. Davenport does not deny the correctness of my analysis, but he says my statements (by which I presume he means my conclusions) are untrue, and that his chlorodyne contains a something which my chemistry cannot detect! Now I am ready to admit that chlorodyne may contain a new alkaloid, the nature of which I have not yet taken the trouble to determine, and which he says he has "compounded

with other organic products, and for the expressed object of preventing detection and misleading the analyser." Now, if Mr. Davenport, or any one else, has discovered a new alkaloid possessing valuable medicinal properties, the Profession will not object to Mr. Davenport keeping the source of that alkaloid a secret, in order that he may reap a pecuniary reward for his discovery. This is legitimate enough; but it certainly appears to me a very extraordinary proceeding on the part of Mr. Davenport to "disguise" his pretended new alkaloid by upwards of 50 per cent. of two such potent agents as chloroform and prussic acid. Mr. Davenport may rest assured that with the rapidly increasing knowledge of chemistry the Profession will not allow an unscientific and unchemical mixture of the most potent and dangerous remedies to be received as "a perchlorate of a new alkaloid!" He may rest assured that, disguise his "new alkaloid" as he may for the purpose of "misleading the analyser," it will not escape the scrutiny of hard-working, zealous investigators, who have devoted their lives to organic chemistry.

Apologising for the length of my communication,

I am, &c.

H. MEDLOCK.

20, Great Marlborough-street, London.

#### BLEEDING IN ARMY MEDICAL PRACTICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—One would suppose, from the tenor of the letter signed "W. O. Markham," published in the last number of the *Medical Times and Gazette*, that your correspondent must be impressed with an idea, of which I would wish to disabuse his mind as speedily as possible, as I believe there is no class of Medical men so keenly and fully alive as Army Surgeons are to the requirements so much needed in the formation of bone and muscle—viz. blood.

I am at a loss to think how, in these days of advancement in science and practical knowledge, your correspondent could for a moment suppose that any class of educated gentlemen could be so lamentably ignorant of the first principles of their Profession as—as a general rule—to bleed largely, even in acute inflammatory disease,—a practice which cannot be too highly deprecated (were it not unnecessary and uncalled-for) in the treatment of soldiers; while we possess such valuable remedial agents as antimony, digitalis, opium, leeches, etc.

For my own part I have long since ceased to use the lancet, except for vaccination, and I believe the habit of phlebotomising has for many years past been quite exploded from military as well as civil practice.

While the mortality in the Army generally—but more especially in the Guards—is much to be deplored, and is justly a matter of the gravest concern, and demanding the closest reflection and consideration, not only on the part of the Profession, but of the public at large, still it must be attributed, and can be traced to other and more fertile sources of disease than malpraxis or venesection.

I am, &c.

M. FENTON MANIFOLD, Staff-Surgeon.

Templemore, March 16, 1858.

#### POST-MORTEM EXAMINATIONS.

[To the Editor of the Medical Times and Gazette.]

SIR,—Dr. Renton asks in the last number of your Journal what is the practice at the London Hospitals with respect to the publicity given to post-mortem examinations? As Pathologist to a large Hospital, allow me to state that our inspection-room is open to all who choose to enter it, and any one is allowed to take notes of the case; and as regards the records made by myself, they are deposited in the museum, open to the view of students and others, permission merely being asked as a matter of form if a copy is requested, a refusal never being offered.

I am, &c.

Guy's Hospital, March 15, 1858.

M.D.

The Queen has been pleased to appoint William Aurelius Harland, Esq., M.D., to be Colonial Surgeon for the Island of Hongkong; and Joseph B. H. Collings, Esq., M.D., to be Auditor-General for the Island of Malta.

#### REPORTS OF SOCIETIES.

#### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 9, 1858.

Sir C. LOCOCK, Bart., President, in the Chair.

Mr. HUMPHRY read a paper on

#### EXCISION OF THE KNEE.

The paper contained an abstract of thirteen cases operated upon by the author. Of these, one (a little child in whom the operation was performed on account of acute suppuration of the joint) died; in four amputation was required, the patients all recovering; and the remaining eight did well, retaining, or with the prospect of retaining, a useful limb in each case. In none were any severe constitutional symptoms excited by the operation, from which it might be inferred that the operation is not in itself one of much danger. Nevertheless, the processes of reparation are more difficult than after amputation; there is likely to be protracted discharge and recurrence of abscesses, etc., and therefore, when the patient is of strumous temperament, or in a very reduced state, amputation is to be preferred to resection. The results of excision are likely to be favourable in proportion as the disease for which it is performed is slight and not acute. Amongst the most suitable cases are those in which the severe stages of disease have passed by, and left the joint crippled, and the limb, consequently, useless. The cases also in which simple inflammatory disease, commencing in the synovial membrane, involves the cartilage and bones, destroying the former to such an extent as to leave little hope of a useful joint, are well suited to excision. But where the disease remains long confined to the synovial membrane, inducing great thickening and various other changes in it, the prospects of excision are less good, because the subjects of this form of disease are generally of strumous temperament, and some portions of the morbid structure are liable to be left, and so become sources of irritation and suppuration. Nevertheless, the author would not altogether decline to perform the operation in this latter class of cases, inasmuch as the remaining fragments of the diseased membrane may fall into a quiescent state and disappear, and the cases do well, provided the bones become firmly united to one another; and if the health begins to fail, the limb can still be removed. The operation is also well suited to some other cases of rarer occurrence, such as certain cases of chronic rheumatic arthritis, knock-knee in the adult, unreduced dislocation, compound fracture of the patella, etc. In performing the operation, Mr. Humphry makes a crucial external incision, takes away the patella, and dissects the soft parts away from the bones no more than is absolutely necessary for the removal of their articular ends, is careful to tie the bleeding vessels, and to secure good apposition of the cut surfaces of the bones and of the skin. The straight position and quiescence of the limb are secured by splints and bandages, which should be changed no oftener than is necessary for cleanliness. The after-treatment was very simple in all the cases related; opiates were very rarely given, and stimulants were generally avoided.

Mr. HOLMES COOTE said he could not agree with the author in the conclusions at which he had arrived. Thirteen cases of resection had been detailed, six of which had been followed by amputation or death. Eight were young persons, and five adults. The author stated that resection should be resorted to only in slight cases, and among these he enumerated knock-knee in the adult, cases of contracted joints, &c. He (Mr. Holmes Coote) might be permitted to state what was the result in the largest hospital in London, having 642 beds, and 389 surgical beds. There had been admitted a vast number of cases of joint disease in every possible form, but during the last twelve months there had been but ten cases of amputation, and not a single case of resection. He ventured to say, in the presence of his senior colleagues, that there was not one case of diseased knee in which any man could have ventured to perform the operation of resection with an easy conscience. Resection should be regarded in a

two-fold point of view, as applying to the young and to the old. In young persons the result was often surprising, whilst in grown-up patients, the varied diseases of the internal organs to which they were subjected rendered the operation far more formidable. Of the ten amputations to which he had referred, three only had been upon young subjects. One of these was a pallid little Irish boy. There was not sufficient disease to require amputation under ordinary circumstances; but as the boy's health suffered, and the lungs were diseased, the limb was removed for the purpose of restoring the general health. Had it not been for the disease of the chest he had no doubt the knee would have ultimately recovered. The next case was that of a child who had met with an accident. The third was a young girl who suffered from necrosis of the femur; the limb was removed, and the patient died. In not one case had it been deemed necessary to perform the operation of resection. It might be said that patients had probably died in consequence of that operation not having been performed; but he had gone over the list of deaths with a view of ascertaining the point, and he found that during the past year there was scarcely a case upon record in which death had occurred from diseased knee. In only one case not operated on had death occurred—the case of a child (under Mr. Lloyd) who died from phthisis. He was unable to say why no operation had been performed. He, therefore, concluded that in children diseased knees, if properly treated, and in the absence of any great cause of excitement, would in time do well. Even in adults but few deaths had occurred from diseased knee-joints. There had been two cases in the hospital during the past year, and in both the men refused amputation. He would also mention the result of experience acquired in the Orthopædic Hospital, where cases of joint disease in every form were constantly brought, many of them having been condemned by other Hospitals, and the patients declining amputation. Since 1851, between 300 and 400 cases had come under the notice of Mr. Tamplin, and the idea of amputation or resection never entered his head. Most of the cases had been relieved. Between the 10th of December last and the 10th of January he could recall six cases of children who came to the Hospital with joint diseases, all of whom told the same tale—that they had been to other hospitals, and that their limbs had been condemned, some for amputation and some for resection; but he was confident that in the course of a few months they would be able to walk far better than they could with a wooden leg, or an excised joint. He did not know of a single case in which resection had been performed in the upper ranks of society.

Mr. SKEY said he listened with considerable attention to the details of the various cases recorded by the author, who he fully expected would himself have concluded from the evidence he had adduced that he ought not to recommend the operation of resection to the Society. There were thirteen cases and five amputations! Had the author calculated that five amputations out of thirteen cases of resection amounted to something like thirty per cent. of failures? Were they in the habit of recommending any operation which exhibited such an enormous proportion of failures? He considered that the inventor, as well as the modern re-introducer of the operation of resection had great claims upon the acknowledgment of the Profession, because he considered the operation to be a great invention or discovery, which might be subservient to the most important uses in the restoration of limbs. But the question was not whether, by sawing off the extremities of a bone, and bringing the two surfaces into contact, a useful limb might be retained; but the question was, Who should determine when such an operation should be performed? The author had alluded to a "judicious selection of cases." He might refer, however, to the statistics mentioned by Mr. Coote, showing that St. Bartholomew's Hospital, in the course of the last five years, had produced no aggregate equal to that of the author alone. Another striking fact was, that these remarkable cases of excision came from comparatively few quarters, and were not spread over the whole of the Profession. It could not be said that one practitioner had three cases and another five; but twelve cases came from one surgeon, fifteen from another, and fourteen from another, the whole number being confined to a few persons with whom the practice appeared to be the rule rather than the exception. It behoved the authorities of the Profession to stand forward and declare where the line should be drawn. He knew of no disease that required more patience, more know-

ledge, more perseverance, more anxious watching day by day before the end was accomplished, than joint disease. He had before him the vision of his own master and friend Abernethy, who narrowly watched cases of that kind week after week, and month after month, and rarely failed in restoring them without having recourse to the operation of resection, which he regarded as a substitute for amputation, and which ought only to be regarded as a *pis aller* when all the other methods of treatment had failed.

Mr. CURLING said he thought Mr. Holmes Coote had been a little too credulous in believing the statements made by the patients coming to the Orthopædic Hospital, to the effect that their limbs had been condemned elsewhere. He believed there was scarcely a case of diseased joint in children requiring amputation, and he did not believe that the statements made to Mr. Coote were true.

Mr. HUMPHRY said his statement was, that excision of the joint should be performed in cases where the joint was not likely to be restored to usefulness. He had remarked that such diseases rarely terminated fatally; and he did not propose excision as a means of saving life, but as a means of restoring a useful limb. It might be true that amputation was not required to save the patient; but the question was, what kind of joint had been left in the cases treated in the ordinary way. Frequently the disease passed off after a time; but when it reached the point to which he had referred in his paper, it was not often that a useful limb was left; but by the operation of excision in such cases the use of the limb was in a great measure recovered, without danger to the patient's life.

Mr. TAMPLIN could not conceive that any surgeon was justified in putting the life of a patient in danger for the chance of restoring a limb, in the way proposed. According to statistics recently published, the operation was fatal in one case out of six; and even from the author's statement it appeared that the operation was not free from risk. As to the result of the more favourable cases, he was not aware that bony union was established except in a few instances; if that did not take place, the operation was a great failure, and there being no ligaments to hold the bones together the limb was like a fall. The first case mentioned was that of simple contraction of the knee-joint—displacement upwards and backwards; and cases of that kind had been from the first successfully treated at the Orthopædic Hospital by extension, and by subcutaneous division of the tendons. Not one fatal case had occurred at the Hospital, and out of the large number of cases of diseased joint in children, he had not seen one that failed to be cured by the most ordinary care and attention. Some time ago, a boy came to the Hospital with thirty openings extending from above the condyles of the femur to the ankle-joint. Amputation had been recommended by more than one surgeon. The boy, on applying, was about 10 or 11 years old; he was now about 17 or 18, and every wound was healed, the joint being no larger than the other, and he had no doubt that the leg would be entirely restored. He had asked the patient whether he would have preferred to have his leg off six years ago, or be in his present condition, with the prospect before him of having a straight leg; and he had expressed but one opinion upon the subject, which was in favour of the course of treatment that had been adopted. Dr. Sigmund, of Vienna, had told him that he never amputated, nor did he think a surgeon was justified in amputating, in young subjects, unless there was a prospect of hemorrhage. The Society then adjourned.

## EPIDEMIOLOGICAL SOCIETY.

MONDAY, MARCH 1, 1858.

Dr. GREENHOW in the Chair.

Dr. RICHARDSON read a paper

### ON THE INVESTIGATION OF EPIDEMICS BY EXPERIMENT.

He commenced by pointing out the weakness of the present system of epidemiological study, which sought after results by trying to descend from the general to the particular. This method lets pass simple laws, which lie at the root of all inquiries. It is painful to say, as a fact, yet a fact proper to be said, that the researches at present so laboriously conducted

do not lead to such proofs of unanimity, or to such positiveness of science, as might, on *a priori* reasoning, be expected from them. The present modes of research may bring out negatives, the present modes of research may bring out partially-accepted positives, i.e. a sufficient of positive evidence to satisfy a section of men, but as yet they have failed to educe such demonstrations, that all who are educated to the same mark can read off the same phenomena by the same process of thought and inductive learning. Dr. Richardson next proceeded to point out carefully such experiments as might be reasonably instituted for the purpose of investigating particular epidemic disorders—especially small-pox, scarlet fever, and typhus; commenting also on the care which should be taken in the selection of the animal subjected to experiment, and showing that in inquiries relating to the three special diseases named above, the pig is the proper animal to be selected, as one more easily susceptible of these diseases than other members of the inferior animal kingdom. Thence leaving proposition for the history of experiment itself, as a means of investigation, the author explained what had been done in recent times towards the production of some diseases artificially, and the information derivable from this form of investigation. He followed up this argument with a minutely recorded account of some experiments performed by himself, in which all the characters of typhus—symptomatology and pathological—were produced by the introduction of alkalies into the system. He showed further, that the typhous condition which could be induced by the injection of animal putrid matters were coincident with, and dependent on, the development of a supra-alkaline condition of the blood; and he connected the pathology of putrid fever, so called, with conditions analogous to those which had thus been artificially produced. In a connected, simple mode of argument, which peculiarly arrested the attention of the audience, the question was next put, Whether, when the virus of a disease is introduced into a healthy animal, so as to reproduce that disease, the symptoms and the pathological changes are due to an absolute reproduction of the virus itself, and to the actual presence of such virus; or whether the virus actively setting up such new changes in the body that a product generated secondarily, and differing in character from the original poison, were the cause of the symptoms? He (Dr. Richardson) was inclined to the latter view, and gave some clear experimental evidence in support of his position. He admitted, at the same time, that further experiments were required, and argued that until this point was defined, no sound progress could be made in the study of epidemics. It is impossible in an abstract to give more than the briefest outline of a communication written in so condensed a style, and opening up for consideration so many subjects, each differing in detail, yet having but one object. But the final propositions laid before the Society were as follows:—1. That by experiment it might be ascertained in what excreta the poisons of certain of the epidemic diseases are located. 2. By what surfaces of the body such poisons may be absorbed, so as to produce their specific effects. 3. Whether the virus of a disease, in reproducing its disease in a healthy body, acts in the development of the phenomena by which the disease is typified primarily or secondarily—i.e. by its own reproduction and presence, or by the evolution of another principle or product. 4. Whether climate, season, or other external influences modify the course of epidemics by producing modifications of the epidemic poisons, or modifications in the system of persons exposed to the poisons.

A discussion followed, in which Dr. Greenhow, Dr. Camps, Mr. Hunt, Dr. Delimer, Dr. James Peird, and Dr. M'William, took part.

Dr. RICHARDSON having replied, the meeting adjourned.

**THE MEDJIDIE.**—The following names were omitted in the list of Medical officers to whom permission has been granted by Her Majesty to accept and wear the Imperial order of the Medjidie conferred upon them by the Sultan. See pp. 1253, 1267, *London Gazette*, March 2, 1858. Officers on the British Staff attached to the Ottoman Army:—4th Class—Acting Inspector-General of Hospitals, Alexander Farquhar; 5th Class—Acting Inspector-General of Hospitals, Frederick Le Mesurier, M.D.; Surgeons:—Samuel Dougan Bird; Thomas Buzzard; Charles Francis Edwards. Dresser—Charles Turner.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, MARCH 4, 1858.

Dr. HAMILTON ROSE, President, in the Chair.

### UREA IN EPILEPSY.

Dr. SIEVEKING referred to the supposed suppression of the secretion of urea as a cause of epilepsy. He related a severe case of epilepsy in which there was excess of urea; and in several cases since examined he found invariably a large excess of urea, which necessarily resulted in great debility.

### DEFORMED RIBS FROM LUNG-DISEASE.

Dr. GRAYL HEWITT exhibited a cast of the upper ribs and cartilages of the left side from a child just under two years old. The preparation was a marked and very interesting example of a deformity frequently observed by Dr. Hewitt in badly-nourished children about this age, who have been the subjects of bronchitis. The cartilages were bent inwards, close to the junction with the ribs, that of the second rib forming a projection inwards of half an inch. The effect was produced during inspiratory efforts by atmospheric pressure, the chest walls being unusually deficient in firmness; and it was remarkable that this extreme degree of deformity existed over a part of the lung peculiarly liable to be affected by collapse in these cases of bronchitis in young children. The lungs were greatly reduced in size, and showed a high degree of collapse or apneumotosis.

### SYCOSIS.

Mr. WERDEN COOKE exhibited two drawings, one showing extensive sycosis of the nose and upper lip existing for two years, and the other the healthy aspect of the face after a month's treatment. Mr. Cooke observed that this disease most commonly affected the chin, which was more difficult to cure, owing to the continuous irritation of the bulbs of the beard. The treatment adopted was linseed poultices to remove the scabs, and then a solution of the manganese c. potassa (3ij. to the pint of water) to be constantly applied. This quite healed the ulcers in one month, and the man was discharged from the Hospital cured.

Mr. HARRY WM. LOBB then read a paper

### ON GALVANISM AS A THERAPEUTIC AGENT.

The author proceeded to explain the theory of the production of galvanic electricity, during the combination of zinc with the oxygen of the decomposed water and sulphuric acid, and the direction of the current, and showed how the penetrative power or intensity of the fluid is increased in the same ratio as the number of separate systems. The secondary, or coil of induction of Professor Faraday, was then described. "I shall now endeavour to show," said the author, "that the nerve-force circulating in the nervous systems of animals bears a very striking resemblance to electricity." He mentioned the *gymnotus electricus* as an example, the electricity generated by that animal being identical with chemically generated electricity, as has been proved by Professor Faraday, M. Gassiot, and others. He then gave a condensed abstract of his views upon the generation and distribution of nerve-force, extracted from his lately published work, "On Nervous Affections." The different kinds of apparatus adapted to the administration of galvanism were then described. He passed a very high eulogium upon the Pulvermacher chain, by which a continued current of electricity in an uniform direction was generated; and he performed the experiment with its aid of decomposing water with a current of electricity which had already passed through the body. The electro-magnetic apparatus was then described, and the method of administering the fluid derived from it, with the class of cases likely to be benefited by the two distinct forms of application. The author advanced the opinion of several French physicians upon the utility of galvanism as a therapeutic agent, and read a communication by M. Hiffelsheim from the *Gazette des Hôpitaux* of the 9th of February, in which that gentleman highly approves of the "continued persistent voltaic current." He then described the effect on the different forms of electricity upon the circulation in the web of the frog's foot, as observed by the aid of the microscope, from which he established this law: "That an inter-

rupted current of voltaic electricity stimulates muscular contraction, and that a continuous current of the same excites the circulation and relaxes muscular contraction." After describing the advantages to be expected from each form of administration, he read the notes of four cases in which he had effected cures or afforded relief with their aid:—1st. A case of stammering, in which, by the administration of electro-magnetism, the patient had been enabled to pass a viva voce examination. 2nd. A case of rheumatism, or rather neuralgia of the brachial plexus, cured with the aid of the continuous current generated by Pulvermacher's chain. 3rd. A case of deafness which had lasted ten years, and had resisted the efforts of several distinguished aurists to relieve; this gentleman had by the use of galvanism so far recovered his hearing as to be able to hear the service in Church, which he had not done for years, as also to obtain an appointment in Australia, which before he could not accept on account of his malady. 4th. A case of severe fracture of the leg, in which through want of use the muscles of the calf had withered and were hardly perceptible: by the aid of electro-magnetism they resumed their form and tone, and the patient (with the exception of a slight limp, caused by the fracture) can now walk perfectly well. The author concluded with an appeal to the Profession not to allow a therapeutic agent of such extreme power and undoubted value to again slip from their hands "into the ready laps of a tribe of greedy and ignorant quacks, always ready to seize upon that which we too easily relinquish to their use; but to study the laws governing this subtle fluid and its administration, and make it of real advantage to the public and ourselves."

Dr. THEOPHILUS THOMPSON had ordered electro-galvanism in partial paralysis. One case of constipation, the result of an injury to the head, resulted in great benefit. He had formerly seen the greatest good produced by galvanism in cases of chlorosis and amenorrhœa; but either from the time employed, or the difficulty of getting this agent properly applied, it certainly had fallen into undeserved neglect by Physicians generally.

Mr. SQUIBB had found electro-galvanism beneficial in facial paralysis, and in cases of innervation, dyspepsia and torpid liver. He related the case of a lady of property, who was enabled to make a very important codicil to her will, and sign it, by the stimulus of galvanism applied by Mr. La Beaume.

Dr. FULLER had not seen much good done by electro-galvanism in paralysis. Of 150 cases electrified in St. George's Hospital, only three derived decided benefit from it. In an inquiry he had made at Guy's Hospital, the same unfavourable report was given. He acknowledged that the muscles of the paralysed limb became less flaccid under its influence, and that in amenorrhœa, when accompanied by the exhibition of steel, it seemed to produce some beneficial effects. In rheumatism he had very rarely seen any good done by galvanism. The cases said to be relieved by this agent ought to be classified, and the mode of applying the instruments should be more distinctly indicated.

Mr. BALLARD wished to know if the author had seen any mineral (lead or mercury) deposited from the body in the electric bath. Certain advertisements pronounced that such effects were obtained.

Dr. HUTCHINSON POWELL thought that without other internal remedies electricity was at present of little avail.

Dr. HANDFIELD JONES had seen life probably saved by galvanism in spasm of the heart. In a case of opium poisoning galvanism was used, and the patient recovered. In atonic affections of the uterus good was likewise effected.

Dr. GRAILY HEWITT referred to a case of hemiplegia, the result of acute softening or clot, in which much improvement was effected; and thought that the introduction of needles to the deep-seated muscles was a desirable improvement in the application of this agent.

Mr. WEDDEN COOKE wished to know if there were really two different actions produced by galvanic agency—viz. a tonic or stimulating action, and an absorbent, sedative action. If it were so, the kind of cases to which electro-galvanism was applicable would be clear. The interrupted current was said to produce the tonic effect, and the continuous current the absorbent effect. He instanced the benefit derived from the use of the interrupted current by relating the case of a gentleman, who, at 40 years of age, from residence in India, and having been attacked by some of the diseases of that

climate, returned to England with his virile powers greatly impaired, so that he feared to marry, as he wished to do. By means of electro-galvanism, and acid given internally, to arrest a discharge of phosphates in the urine, which was said by some notorious quacks to be seminal fluid, he was quite restored.

Mr. LOBB having replied, the Society adjourned.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in Classics and Mathematics on Tuesday and Wednesday, the 16th and 17th inst. :—

ATTWOOD, JAMES, Southwick-place, Hyde-park-gardens.

BROUGHTON, HENRY TODD, Manor-road, Bradford.

CARTER, FREDERICK, Billericay.

COOKSON, SAMUEL, Needham-market.

COOKSON, ALBERT, ditto.

CORBIN, WILLIAM JOHN, Hampstead-road.

COX, HENRY WILLIAM, Dorchester.

DOOLEY, WILLIAM, Liverpool.

ECULES, EDMUND, Longridge, near Preston.

EDDOWES, WILLIAM, Pontesbury, Shropshire.

FAWCETT, FRANCIS M., Yatm.

GALE, HENRY STANLEY, 47, High Holborn.

HAYDEN, WILLIAM GALLIMORE, High Wycombe.

KEMPE, CHARLES MARSHALL, Falmouth.

KENT, JOHN GEORGE DAVIS, Brigg, Lincolnshire.

LITTLE, FREDERICK, Eye, near Peterborough.

MEECE, JOHN THOMAS, Guy's Hospital.

MISKIN, GEORGE ALBERT, York-road, Lambeth.

MORRISH, THOMAS FOX, Christ's Hospital.

MORTON JOHN, Holbeach.

PAGE, WILLIAM IRVING, 3, Ulster-place.

PHILLIPS, GEORGE RICHARD T., Pentonville-road.

PICK, THOMAS P., Dalemene-street.

REES, HOWARD, 17, Canonbury-square.

SQUARREY, CHARLES EDWARD, Salisbury.

STUBBS, HENRY, Wye.

SUTTON, CHARLES FREDERICK, Wragby, Lincoln.

THOMAS, DAVID BOWEN, Newcastle Emllyn.

TROTTER, ARTHUR E. H., Stockton.

WAGSTAFFE, WILLIAM WARWICK, Walcot-place, Lambeth.

WAGSTAFFE, MATTHEW MAWE, ditto.

WATTS, WILLIAM EYRE, Hampstead.

WINTLE, RICHARD, Kensington.

## DEATHS.

**BAYLE.**—M. A. L. J. Bayle, nephew of H. L. Bayle, so well known by his works on pathological anatomy, and great-grand-nephew of the celebrated author of the "Dictionnaire Historique," has just died, aged 59. He commenced his Medical career by a brilliant dissertation on primary chronic meningitis, in which he first made known the existence of a disease which is now known to be so prevalent in France, viz. the general paralysis of the insane. He pursued the subject in various other works on mental pathology, and in 1854 received the Academy prize for his essay on the "Organic Cause of the general Paralysis of the Insane." He also published the well-known collection of memoirs, the "Bibliothèque de Thérapeutique," and was editor of the influential publication, "Encyclopédie des Sciences Médicales." He was one of the chief contributors to the pages of the "Revue Médicale;" and had recently published a summary of his Medical doctrines in his "Éléments de Pathologie Médicale."

**CHIBNALL.**—On the 9th November, at Cuba, West Indies, Charles Chibnall, aged 27.

**FAITHFULL.**—On the 1st February, at Bombay, John James Faithfull, Surgeon, Bombay Army, aged 39.

**LANG.**—On the 13th instant, at Howley-place Villas, Maida-hill, C. H. Christian Lang, M.D., aged 76.

**MAGRATH.**—On the 17th of February last, at Kingston, Jamaica, Joseph Magrath, M.R.C.S. Lond. 1812, aged 69, for many years Senior Surgeon to the Public Hospital, and President of the College of Physicians and Surgeons of this Island.

**PRING.**—March 6, at 2, Park-row, Bristol, aged 38, John Pring, M.D., King's Col. Aberdeen, 1854; M.R.C.S. Eng. 1852.

**SHEAN.**—On the 11th inst. at Southsea, Robert Shean, M.D. Edin. 1836; late of 7th Royal Fusiliers, aged 66.

**SIMMONS.**—On the 7th inst., at Hatcham, Nicholas Fenwick Simmons, M.R.C.S. Eng. 1837, upwards of seventeen years Surgeon of the Royal Naval School, New Cross.

**BREEDING LEECHES.**—M. de Quatrefages has communicated to the Institute various essays made at Algiers and in Paris, to show that the little leech called in Africa *dragon* is as vigorous and profitable as the French leech. He points out the means of multiplying it and of turning it to good account, and on that occasion he states a fact of the highest interest: the use of a small apparatus which he calls a *domestic marsh*, that every one can construct for himself with a tube of sand-stone, and in which leeches may be conveyed from one place to another without any kind of danger to their preservation. Nay more, these annelides, deposited in the earth contained in these apparatuses, multiply there admirably. M. de Quatrefages obtained thousands of young leeches by that process.

**ADDRESS TO THE LORD LIEUTENANT OF IRELAND.**—On Monday the 15th inst., a deputation from the Apothecaries' Hall of Dublin waited by appointment on the Earl of Eglinton at the Castle, to congratulate his Excellency on his resumption of the office of viceroy of Ireland. In reply, his Excellency said, "I am aware of the great utility of men of your Profession and companies such as yours, and you will not find me backward in assisting you in carrying out measures which are likely to increase civilization and improve the sanitary condition of the community."

**THE ASSOCIATION OF MILITIA SURGEONS IN IRELAND.**—An important meeting of this body was held in the Rotunda on the 13th instant, Dr. Bushe, Mayo Rifles, president, in the chair; Dr. Guinness, County Dublin Regiment, honorary secretary; when after several communications had been read relative to surgeons being placed on the staffs of their respective regiments on a more permanent footing, amount of pay, etc, for which object a deputation is to wait on General Peel, Secretary of State for War, it was unanimously resolved that the Society be amalgamated with that of the English and Scotch, into one general association for the welfare of the militia service, and their mutual interests as a professional body.

**AMERICAN VIEWS OF CANCER-CURING.**—The editor of the *New York Journal of Medicine* observes: "It will be seen, by referring to the review department of this number, that the novelty in the treatment of cancer, which the learned Surgical staff of the Middlesex Hospital accord to Dr. Fell's method, namely, that of incising the cancerous tissue before the application of the caustic, is not new, but, in fact, was a favourite practice of some of their own eminent, but evidently long-forgotten surgeons. The humiliation of these *savans*, who have been for the last year gravely sitting in judgment upon one of the most transparent systems of quackery yet practised, is complete. They are condemned by the voice of their own fathers, who have arisen from the dead to claim the honours which their degenerate sons have attempted to confer on a shallow empiric."

**ACTION OF LIGHT ON ANIMALS.**—M. Bernard has been making some curious observations on the action of light on animals. It appears from his experiments that differently coloured lights, or, in other terms, the different rays of the solar spectrum, have a very different influence on the development of young animals, on the hatching of eggs of insects, etc. The experiments of M. Bernard are simple enough, and can be repeated at leisure by any physiologist. Taking a certain quantity of eggs of the common blue-bottle fly (*Musca carnaria*, L.) he divides them into separate groups and hatches them under different coloured glass jars. If in four or five days' time we examine the larvæ that are produced, we shall find that those coming from the eggs which were placed under the blue and violet coloured jars are far more robust, or more fully developed than the others. Those coming from eggs which were placed under the green jar have taken the least development. By more minute examination we shall observe that after the larvæ of the blue and violet jars, come

next, in strength and development, those hatched under the influence of red light; then, those under the yellow and white (or transparent) jars, and finally those of the green. The series, beginning at the coloured light most favourable to the development of these eggs and larvæ, may thus be set down:—Violet, blue, red, yellow, white, and green. The larvæ developed in a given time in violet light are more than three times as large as those hatched and bred in green light. On birds and mice being placed under the same coloured jars, no difference was observed in any physiological function; their respiration, for example, was exactly the same in these circumstances as if they had been placed in ordinary day-light. The author attributes this to the circumstance that light cannot come in contact with the bodies of these animals, on account of their feathery and hairy coverings. Frogs, on the contrary, being animals with whom cutaneous respiration is very perceptible, give different results:—A given weight of frogs living entirely in green light, evolve far more carbonic acid in a given time, than the same weight of frogs under the influence of red light. If the frogs are deprived of their skin the result is precisely the reverse.—*Illustrated Inventor.*

**THE FEVER IN BERMUDA.**—The House of Commons has ordered the publication of the copy of a despatch from the Governor of Bermuda, enclosing a report from the Commissioners appointed to inquire into the first appearance and the spread of yellow fever at Bermuda in the year 1856. The Commissioners conclude that the said epidemic was not introduced *ab extra*, but that it originated in the colony itself; that it appeared, not at one, but at several points, distinct and widely separated (at two such points simultaneously); that it did not spread through contagion or infection, but through the same causes that had given rise to it—an inferred epidemic constitution of the atmosphere, exploding in attacks of the disease where it encountered the other required elements, predisposition in individuals, bad sanitary condition in localities, or both combined; that at present nothing is known which is calculated to prevent absolutely a recurrence of epidemic yellow fever in the colony; that some new organisation is required to carry out sanitary measures effectively, and that quarantine should be applied only to ships with yellow fever, and not to the crews of such ships.

**ASSOCIATION OF GENERAL MEDICAL PRACTITIONERS OF IRELAND.**—The Annual Meeting of the above body was held in the Board-room of the Apothecaries' Hall of Dublin, on Wednesday last, St. Patrick's day, John Nalby Esq., M.D., President, in the chair. A report of the proceedings of the past year was read, in the absence of the Secretary, by Mr. Vance, the Treasurer, who made special allusion to the efforts of the Association on the subject of Medical reform. A resolution was unanimously adopted, that the Association gladly hail the announcement made in Parliament that Lord Elcho intends shortly to bring in a Bill for a reform of the Medical Profession, and that the President be instructed to furnish his Lordship with the views of the Association, as embodied in their address recently sent to the Right Hon. W. F. Cowper, M.P. The following were elected officers of the Association for the ensuing year:—President, Dr. Moore; Vice-President, Mr. Gorman; Treasurer, Mr. Vance; Librarian, Mr. Shaw; Secretaries, Dr. Ryan and Dr. Long. A vote of thanks to the outgoing President, Dr. Nalby, for his very valuable services during his year of office, was unanimously passed.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, March 13, 1856.

### BIRTHS.

Births of Boys, 1043; Girls, 964; Total, 2007.  
Average of 10 corresponding weeks, 1848-57, 1683.

### DEATHS.

	Males.	Females.	Total.
Deaths during the week ... ..	771	716	1487
Average of the ten years 1848-57 ... ..	695.8	590.7	1186
Average corrected to increased population ... ..	...	...	1306
Deaths of people above 90 ... ..	...	...	...
Deaths in 15 General Hospitals ... ..	37	34	71

## DEATHS IN SUB-DISTRICTS FROM EPIDEMICS.

## METEOROLOGY.

From Observations at the Greenwich Observatory.

Mean height of barometer ...	29.526 in.
Mean temperature ...	54.7
Highest point of thermometer ...	50.8
Lowest point of thermometer ...	23.6
Mean dew-point temperature ...	29.9
General direction of wind ...	N.W.
Whole amount of rain in the week ...	0.25 in.
Amount of horizontal movement of air in the week ...	865 miles

## TO CORRESPONDENTS.

*A Non-Medical Reader.*—The letter has been forwarded to Mr. Mackenzie.

*Dr. Ogilvie's case of Poisoning by Strychnia* has arrived, and shall appear in an early number.

*G.*—There can be no doubt of the possibility of perfect recovery in such cases.

*Isicus.*—We know nothing of the individual named. The book is not one to be relied on—quite the contrary.

Papers by Dr. Halford, Mr. Newman, Mr. Welford, Mr. Jackson, Mr. Lawrence, Dr. Silvester, Mr. Byrne, Mr. Mofton, Dr. Whitehead of Boulogne, and Mr. Thompson, are in type, but are unavoidably postponed; as are reports of the Pathological, and Western Medical Societies.

## PRACTICE IN CANADA.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I shall feel greatly obliged if you will kindly inform me, in the next number of your journal, if an English Surgeon can practise in either Upper or Lower Canada without passing an examination there? If there is a good chance of succeeding in general practice? and which is considered the best locality for settling? An answer to the above will greatly oblige me.  
M.R.C.S.E.

[Perhaps some correspondent with personal knowledge of Canada will reply to the above.—Ed.]

## ADVERTISING SURGEONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—With reference to the advertisement extracted from a provincial paper and commented on in last week's Gazette, I beg to state that the office of House-Surgeon to this Hospital has never been filled by any one bearing the name of "William Preston." I am, &c.  
Guy's Hospital, London, S.E. JNO. CHAS. STEELE, Superintendent.  
March 16, 1858.

## INDISCREET PUBLICATIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I forward you by this post one of the numerous filthy publications which are constantly being thrust into the bosom of families by unprincipled quacks; three married officers of this ship have each received a copy by this morning's post. It is full time some measures were enacted to rid society of this class of impertinent pretenders, who are constantly doing their utmost to poison the minds of our youth, and at the same time are an annoyance to persons of maturer years. I am, &c.  
H.M.S. "Implacable," Devonport, L. H. J. HAYNE, R.N.  
March 11, 1858. M.R.C.S. Eng.

[The work alluded to by our correspondent is entitled "Human Frailty." It is published, according to the title-page, by Messrs. Sherwood, Piper, and Co., 23, Paternoster-row, London, and written by *Medicus*, 19, Berners-street, Oxford-street, London. We think the tendency of this disgusting production so demoralising, that we have forwarded the copy to the Society for the Suppression of Vice, and sincerely hope that at least one prosecution may be instituted under Lord Campbell's Act.—Ed.]

*ERRATUM.*—In last No., p. 280, col. 2, line 29, for *Hornton* read *Thornton*.

*A Secretary.*—We thought it advisable to allow Mr. Acton's long letter—objecting to our criticisms on certain of his schemes—to appear without comment. But a remark of his requires notice, which says, that we have only superficially looked at his book, for had we read it we should "have found that domiciliary visitation was not proposed by me." Now, in answer to this, we must observe that Mr. Acton cannot know what has been published under his name, or we do not know the ordinary value of words. At p. 123 of the work on Prostitution, known as Mr. Acton's, the author says, "It might be insisted on . . . that all houses and persons notoriously harbouring prostitutes, if not already under the

operation of licensed victualler's or common lodging-house acts, should be compelled, or compellable to become so." He goes on further, "Thus we should bring all casinos, pleasure-gardens, brothels, and accommodation-houses, not already under supervision as licensed public-houses, under the action of a special branch of the police, who should have powers of domiciliary visitation," &c. And he adds, admitting the tenderness of the ground he is treading, "It is fair to say that more than one of the most eminent lawyers who have illuminated the seat of justice in this country, have expressed themselves against domiciliary visitation as 'contrary to the spirit of English law.'" That the term brothels above mentioned includes all houses where prostitutes reside is evident from other parts of the work. At p. 16, all houses occupied by prostitutes are generically termed brothels. And at p. 96 the author speaks of lodging-houses crowded together, and called generically by the police "notorious brothels." As far as we can find, he gives no description of the particular quality of the lodging which is to exempt the prostitute inmate from domiciliary visitation. According then to his plan, as we plainly read it, every lodging-house that notoriously holds a prostitute or prostitutes is to be subjected to domiciliary visitation; and if this is not the thing in full force, we know not what would be deemed to be so. The other parts of Mr. Acton's letter refer merely to matters of opinion, concerning which we differ from him. He says "yes" of them, and we say "no." Whose judgment is most correct time alone can decide.

## COMMUNICATIONS have been received from—

Dr. SYMONDS, Clifton; Mr. WILDS, Dublin; Dr. CUMMING; Dr. BROWN-SQUARD, Paris; Dr. COILVIE, Alexandria; Dr. WILKS; Mr. WIELIN, Southampton; Mr. WINDSOR, Manchester; SECRETARY, GENERAL BOARD OF HEALTH; Mr. BAKER BROWN; Dr. W. COOKE; Mr. GRIFFIN; Mr. HAYNE, R.N.; Mr. LANGDON BROWN; PRESIDENT AND COUNCIL, ROYAL MEDICAL BENEVOLENT COLLEGE; Mr. RIVERS; Mr. BARLOW; PRESIDENT AND COUNCIL OF THE PHOTOGRAPHIC SOCIETY; Mr. BIRTWHISTLE; Mr. M'DERMOTT; Mr. J. HARRISON; Mr. HOWARD; Mr. J. DAVIES; Dr. M'KENZIE; J.B.; MEDICUS; Dr. LONGTON; Dr. R. COULSON; Mr. PHILLIPS; Mr. J. ALLEN; Mr. R. DAVIS; Mr. J. BROWN; Mr. COATES; Mr. J. GRAHAM; Dr. G. HEWITT; STAFF-SURGEON MIDDLEMORE; Mr. EDWARDS; Mr. WAKEFIELD; Mr. HART; Mr. CLAY; Dr. WENTWORTH.

## APPOINTMENTS FOR THE WEEK.

March 20, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; Westminster, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."  
MEDICAL SOCIETY OF LONDON, 8 p.m.: Dr. Andrew Clark, "On a Form of Colonorrhoea, or Follicular Disease of the Colon, accompanied by Increased and Vitiated Secretion of the Mucous Membrane."  
GUY'S HOSPITAL SOCIETY, 8 p.m.: Mr. Durham, "On Sleep in Health and Disease."

## 22. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 3 p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Huxley, "On Biology."

## 23. Tuesday.

Operations at Guy's, 1 p.m.  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8½ p.m.: Mr. Toynbee, "On Ankylosis of the Staples to the Fenestra Ovalis;" Dr. Tyler Smith's Case of "Inversion of the Uterus."  
ZOOLOGICAL SOCIETY, 9 p.m.  
METEOROLOGICAL SOCIETY, 7 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."

## 24. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m., Orthopaedic Hospital, 3 p.m.  
GEOLOGICAL SOCIETY, 8 p.m.

## 25. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL SOCIETY, 8½ p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."  
ROYAL INSTITUTION, 8½ p.m.: Professor Tyndall, "On Heat."

## 26. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.  
ROYAL INSTITUTION, 3 p.m.: Richard J. Barlow, M.A. F.R.S.V.P. and Sec. R.I., "On Mineral Candles, etc. manufactured at Belmont."

## EXPECTED OPERATIONS.

Westminster Hospital.—The following operations are expected on Tuesday next, at 2 o'clock:—  
Wutzer's operation for radical cure of hernia, by Mr. Holt; amputation at the shoulder, Mr. Holthouse.  
King's College Hospital.—The following operations will take place on Saturday, March 20, at 2 o'clock:—  
For ectropion, by Mr. Bowman; for diseased carpus, trephining tibia, and double hare-lip, by Mr. Fergusson; amputation of foot (Pergoff's), by Mr. Partridge.

## NOTICE.

**West-end Dispensing Establishment.**

In consequence of numerous errors which have occurred of late years through the carelessness of inexperienced Dispensers of Medicine, Messrs. CURTIS deem it expedient to assure the Profession and the Public that their method of transacting business precludes the probability of mistake, thus offering peculiar advantages for the Dispensing of Medicines, and fulfilling the best wishes and interests of the Profession and the Public.

**Messrs. Curtis continue to receive**  
the most satisfactory results from Medical Men in favour of  
"P.A.S.M.A."

(Or, HEALING POWDER),

THE REMEDY FOR

**EXCORIATIONS, BURNS, ULCERS, AND ERUPTIONS; ALSO, A PROPHYLACTIC OF ABRASIONS IN DELICATE, TENDER, AND IRRITABLE SKINS.**

Messrs. CURTIS feel called upon to caution Medical Men against spurious imitations, and to inform them that the genuine is not a Metallic Preparation (nor a secret one), the Proprietors having informed the Profession of its exact composition.

Messrs. CURTIS also invite the attention of Medical Men to their **NEW PHOSPHATE, or PULV. EBORIS PREPARATA**, as prescribed by Dr. Stocker in Rickets, etc. etc. (Vide "The Lancet," Dec. 19th, 1857.) Also to their

**EXPRESSED JUICES, LIQUORS, MEDICINAL EXTRACTS, TINCTURES, etc. etc.**

**CURTIS & CO.,** Pharmaceutical and Dispensing Chemists, (Wholesale and Retail), 15, Crawford-street, London. Established 1820.

ESTABLISHED 1830.

**M. and R. Jewell beg to express their**

thanks for the encouragement they have received from the Medical Profession, and hope for a continuance of their favours at their Medical Glass and Bottle Warehouse, 53, Howland street, Tottenham-court-road, where an extensive Stock is always kept on hand, at the lowest prices. Measures, Stopped Bottles, Pedestal Mortars, etc. etc. Orders punctually attended to. List of prices forwarded post free.

**The Medicated Cod Liver Oils,**

comprising  
**OLEUM MORRHUE CUM QUINA.**

Prepared only by **SAVORY and MOORE**, 143, New Bond-street.**Liquor Pepsinæ.—A Convenient and**

**EFFICACIOUS PREPARATION BY**  
**SAVORY and MOORE**, 143, New Bond-street.

**Dr. James's Fever Powder.—This**

celebrated Medicine, when genuine, is found by experience to be more mild and certain in its effects than any other preparation. Its efficacy is most certain when freely given on the attack of fever, measles, sore throat, recent cold with cough, and other inflammatory disorders. In rheumatism and chronic complaints it has performed the most extraordinary cures when used with perseverance. Dr. James's Powder is still prepared by Messrs. Newbery from the only copy of the process left by Dr. James in his own handwriting. Observe the name, "J. Newbery, 45, St. Paul's Churchyard" London, engraved on the Government Stamp. Price for dispensing, 6s. per oz.; also in packets at 2s. 9d.—Established A.D. 1746.

**Great Saving in the Purchase of Six**

**GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS,** assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.
6 and 8 oz., any shape, plain, or graduated, ..	8	0 per gross.
3 and 4 oz. ditto ..	7	6 do.
1 oz. Moulded Phials ..	4	6 do.
1 oz. ditto ..	5	6 do.
1 1/2 oz. ditto ..	6	0 do.
2 oz. ditto ..	7	0 do.

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

**Wines from South Africa.—Port,**

**SHERRY, etc., TWENTY SHILLINGS PER DOZEN.** These Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome, and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices. A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy, and the opinion formed is that they are worthy of being patronized."—Clerical Journal, October 22, 1857.

**EXCELSIOR BRANDY,** Pale or Brown, 15s. per gallon, or 30s. per dozen. Terms—Cash. Country orders must contain a remittance. Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

## "NEMO SIBI VIVAT."

**New Equitable Life Assurance**

COMPANY.—Offices, 449, Strand, Charing-cross.

## TRUSTEES.

G. H. Barlow, M.D., Union-street, Southwark.  
James Copland, M.D., F.R.S., 5, Old Burlington-street.  
Sir James Duke, Bart., Alderman, M.P. for the City of London.  
Sir Charles Hastings, M.D., D.C.L., Worcester.  
Richard Partridge, Esq., F.R.S., New-street, Spring-gardens.  
John Probert, Esq., 6, New Cavendish-street.

## DIRECTORS.

Chairman—George H. Barlow, M.D., 5, Union-street, Southwark, Physician to Guy's Hospital.

Deputy Chairman—John Weston, Esq., Hulme-House, Hampton-wick.

George Chapman, Esq., 23, New-street, Spring Gardens.

Richard Jobb, Esq., 9, Old-square, Lincoln's Inn.

Thomas B. Jones, Esq., Holland-road, Brixton.

J. C. W. Lever, M.D., 12, Wellington-street, Southwark, Obstetric Physician to Guy's Hospital.

W. J. Little, M.D., 34, Brook-street, Grosvenor-square, Physician to the London Hospital.

Richard Partridge, Esq., F.R.S., 17, New-street, Spring Gardens, Surgeon to King's College Hospital.

Samuel Richards, M.D., 38, Bedford-square.

Robert Smith, Esq., 20, Endsleigh-street, Tavistock-square.

W. Tyler Smith, M.D., 7, Upper Grosvenor-street, Grosvenor-square, Obstetric Physician to St. Mary's Hospital.

J. Grace Stevens, Esq., 38, King-street, Covent-garden.

## CONSULTING PHYSICIANS.

Benjamin Guy Babington, M.D., F.R.S., 31, George-street, Hanover-sq.

James Copland, M.D., F.R.S., 5, Old Burlington-street.

## CONSULTING SURGEONS.

William Fergusson, Esq., F.R.S., 16, George-street, Hanover-square.

J. Banald Martin, Esq., F.R.S., 71, Grosvenor-street, Grosvenor-square.

## MEDICAL EXAMINERS.

F. J. Farre, M.D., F.L.S., 7, Montague-street, Russell-square, Physician to St. Bartholomew's Hospital.

Thomas H. Wakley, Esq., F.R.C.S., 7, Arlington-street, Piccadilly, Surgeon to the Royal Free Hospital.

By a small annual payment, Life Assurance secures the following provisions:—

1. Policies at death of husband, father, or son, so that widows and child on are not left destitute.
2. Settlements secured in marriage contracts.
3. Endowments to children; so that funds are provided for apprenticeships, &c.
4. Security to creditors to provide against the death of their debtors.
5. Security to the debtors themselves; so that at death their estate or business is unencumbered by debt.
6. Capital to meet the loss entailed by the falling in of annuities or reversions.
7. Funds to meet renewals of leases at increased rents.
8. Sums of money payable to the assured themselves on attaining a certain age.

The attention of the Medical profession is called to the following scale of fees payable by the Company on business introduced by the medical attendant:—

Fee of £2 2s. for every assurance of £250 and upwards.

Fee of £1 1s. for every assurance of £100;

and, in addition, a commission of 10 per cent. on the premium of the first year, and five per cent. on subsequent payments.

Prospectuses and proposal forms may be obtained on application to  
**FREDERICK BIGG, Actuary and Secretary.**

449, Strand, Charing-cross.

**For Use Medicinally, in all Diseases of**

the **STOMACH, CHEST, etc.**, for dressing and deodorizing cancer and all foul wounds, for purifying sick chambers, for embalmment of the dead, etc. Mr. JASPER ROGERS'S PATENT CARBONIZED PEAT MOSS. The various kinds of powder and lozenges are prepared solely by the Health of Towns Improvement Company. Sole Wholesale Agent, Joseph G. Thompson, Esq., 3, Adelaide-place, London-bridge, London, E.C., and 5, Donegal-square, Belfast; sold by Mr. W. L. Bird, Pharmaceutical Chemist, 42, Castle-street, East, Oxford-street, W.; Mr. J. Johnson, Chemist, 123, Upper-street, Islington, N., London; Messrs. Bewley and Evans, Dublin; and all respectable Chemists. See extracts from publications on the subject, with the preparations.

**The Best Food for Children, Invalids,**

and others.—ROBINSON'S PATENT BARLEY, for making Superior Barley-Water in Fifteen Minutes, has not only obtained the Patronage of Her Majesty and the Royal Family, but has become of general use to every class of the community, and is acknowledged to stand unrivalled as an eminently pure, nutritious, and light food for Infants and Invalids; much approved for making a delicious Custard Pudding, and excellent for thickening Broths or Soups.

ROBINSON'S PATENT GROATS, for more than thirty years, have been held in constant and increasing public estimation, as the purest farinæ of the oat, and as the best and most valuable preparation for making a pure and delicate GRUEL, which forms a light and nutritious supper for the aged, is a popular recipe for colds and influenza, is of general use in the sick chamber, and, alternately with the Patent Barley, is an excellent Food for Infants and Children.

Prepared only by the Patentees, ROBINSON, BELVILLE, and CO., Purveyors to the Queen, 64, RED LION-STREET, HOLBORN, LONDON.

Sold by all respectable Grocers, Druggists, and others, in town and Country, in Packets, at 6d. and 1s., and in Family Cansisters, at 2s. 6d., and 10s. each.

## ORIGINAL LECTURES.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## LECTURE III.

ON INDIRECT FRACTURES OF THE BASE  
OF THE SKULL.

At the close of my last lecture I was speaking of direct fractures of the base of the skull, and I now proceed to the consideration of its indirect fractures.

If, on the one hand, direct fractures of the base are very rare, indirect fractures, on the other hand, are very common in this region. Indeed so common are they that they form by far the greater portion of the fatal cases of injuries of the head which occur in our Civil Hospitals. It is not that these fractures, however extensive, are in themselves more dangerous than those of the vault; the great danger lies not in the fractures, but in the deadly mischief done to the organs contained within the skull.

For a long series of years, fractures of the base of the skull were, for the most part, looked upon as fractures by "contre coup." And so much was this the case at one time, that fractures of the base, and fractures by "contre coup" came to be all but synonymous terms. Modern researches, however, have clearly demonstrated that fractures by "contre coup" are as uncommon about the base, as they are in the other parts of the skull.

Let us not, however, now run into the opposite extreme, and deny altogether the existence of these fractures by "contre coup" at the base of the skull.

A close analysis of fractures of the base of the skull proves that the bones of this region may be broken in several different ways.

For instance, a blow dealt upon the perpendicular portion of the frontal may give rise to a fracture of the orbital plate of this bone, without any injury whatsoever being perceptible in the intervening osseous tissue.

In a man, who was admitted into St. George's Hospital in 1849, with two large scalp wounds denuding the bone on the vertex, the left orbital plate was the only part of the skull where a fracture was detected; it was a mere fissure, half an inch in length, passing perpendicularly towards the lesser wing of the sphenoid. No blood was extravasated in the neighbourhood of the fracture. The man died of intra-cranial suppuration with purulent infection.

A case very similar to this is related by Boyer. A man fell from the top of a house on his forehead; the injury appeared to be over the left eyebrow; there was no fracture here, however, but the corresponding orbital plate was broken into splinters.

Cases such as these are of very rare occurrence, and you will find but very few recorded by modern Surgeons.

Again, the central bones of the base may be the only bones broken when the front and back part of the head have been caught between two opposing forces.

A man, 36 years of age, while carrying a heavy piece of timber, fell backwards, and struck the back part of his head against the pavement, the piece of timber at the same time falling on his forehead. No fracture was detected either in the occipital, or in the perpendicular portion of the frontal, but the body of the sphenoid presented an extensive and comminuted fracture, from which linear fractures were traced in various directions. One fissure ran forwards into the cribriform plate of the ethmoid, and slightly into the left orbital plate of the frontal. Another fissure, passing outwards, reached the squamous suture, and a third, passing outwards and backwards along the anterior surface of the petrous portion of the temporal, was traced as far as the squamous portion.

But cases such as these are also of rare occurrence.

Again, fractures of the base may be produced by the force acting from below upwards, the shock being transmitted to the skull through the intermedium of the spinal column. And here we may also find, as in the previous instances, that the broken bones are away from the spot which was struck.

On the 24th of May, 1843, a man, aged 40, strong and stout, alighted from a height of 12 metres directly on to his feet. He was a little shaken, but did not lose his senses, walked home, and on the following day went to work again. Four days after this, however, he began to feel some acute pain about the right ear, became restless, and was unable to sleep at night. Three weeks afterwards came intense pain in the head, and a squint inwards of the right eye was for the first time observed. He was admitted into the Pitié, under the care of M. Nonat, who bled, leeches, and blistered him, but all to no purpose. Feeling no better, this man left the Pitié, and shortly afterwards got admitted into Beaujon, under the care of M. Robert. He was then much in the same state as before, with intense and continuous pain in the head, and flying pains about the limbs. Sundry preparations of aconite were prescribed, but without any benefit; and thus he went on until the 20th of September, when he was suddenly seized with violent delirium, and died within twenty-four hours, three weeks after his admission into Beaujon, and nearly four months after the accident. At the examination of the body, the two posterior clinoid processes were found broken off; the right petrous bone presented an extensive fracture running across its inner third, and thus breaking off a large piece of this bone. These were the only injuries done to the bones of the skull. The visceral arachnoid was thickened and opaque, especially at the part corresponding to the fracture, and at the posterior lobes of the brain. The sixth pair of nerves on the right side was torn across opposite to the fracture.

A man, in a drunken fit, threw himself out of a second floor window, and was picked up apparently dying. Both knees and the right elbow were most severely bruised; the left radius was broken close to the wrist, and there was a small scalp wound over, and parallel to, the right brow, with severe bruising of the eyelids. Such being the only external injuries which could be detected, this man was thought to have alighted on his knees. He died three days after the accident. The only injury about the head was a fracture at the apex of the right petrous bone, with another small fracture running along the right side of the sella Turcica, and laying open the sphenoidal sinuses. The bones of the right orbit presented no traces of injury. The liver and the right lung were extensively ruptured.

A man alighted on his heel from a height of 10 to 12 metres. He was terribly shaken, and was evidently suffering from severe internal mischief about the belly. For two days he lost a good deal of blood from the nose, and lingered four days after the accident. The heel was smashed. The bones of the leg and of the thigh were not injured, but the sacro-iliac synchondrosis was torn right open. The walls of the belly, and the organs contained in this cavity were severely and extensively bruised. The only injury detected about the head was a fracture of the cribriform plate of the ethmoid. Every other bone in this region was perfectly sound.

In the three cases which I have just mentioned, the patients alighted either on the knees, or on the feet, and the shock from thence was evidently transmitted through the spine to the base of the skull. Cases such as these are seldom met with. But this impulsion of the spinal column forcibly against the occipital condyles is nevertheless supposed by some Surgeons to be the cause of the fractures so frequently observed about the base of the skull.

The late Mr. Earle observed to Sir Benjamin Brodie that he had not known a fracture of the base to take place, except where the blow seemed to have operated in such a manner as to impel the occiput forcibly against the atlas, the line of fracture passing through the former bone, where it rests upon the latter. And Sir Benjamin Brodie states that his own experience corresponded very nearly with that of Mr. Earle.

Mr. Hilton, in his valuable lectures on the cranium, recently published, also expresses the opinion that the frequency of the fractures occurring through the petrous bone is dependent upon the forcible impulsion of the spine against the occipital bone.

"In a fall on to the top of the head, from a great height,"

says Mr. Hilton, "the body comes with considerable force or violence against the occipital condyles, and the vibrations thus generated, being conducted by the dense ridge of bone extending from each condyle to the jugular process, are thence communicated to the petrous bone, at the point where it is joined or united to the occipital. Thus starting from the point of union between the jugular process of the occipital and the petrous bone, and pursuing the direction in which the vibrations travel, the fracture usually intersects and ruptures the membrana tympani."

To illustrate these remarks, Mr. Hilton performed the following experiment. "An ordinary adult skull was fixed on a firm support, with its vertex downwards, and its base upwards—a strong piece or bar of wood was placed across the occipital condyles, and then, by means of a hammer, a stout blow was applied as evenly as possible over its centre. The result of this was a fracture through the petrous bone, the line of fracture intersecting the membrana tympani."

That certain fractures of the base may be thus produced, there is no doubt; but that the great majority of fractures of this region are not thus dependent upon the shock of the spine, there is also, to my mind, no doubt at all.

If we look somewhat closely into these fractures of the base of the skull, we shall soon perceive that many of them are exactly limited to certain regions, beyond which they do not extend, and that the fracture in such cases has nothing whatsoever to do with the condyles of the occipital bone. Before I proceed further, let me illustrate this by three specimens from the museum of St. George's Hospital.

In this preparation (a) the injury of the base of the skull does not extend beyond the bones of its anterior fossa. The upper wall of the right orbit is broken into several fragments, and the cribriform plate of the ethmoid, and the lesser wing of the sphenoid, are separated from the frontal. The patient having fallen from a great height, was admitted into St. George's Hospital in October 1842, and died within a few hours, the brain having been extensively bruised.

In this second preparation (b) we have a well-marked instance of a fracture confined to the middle fossa of the skull. The fracture commencing at the posterior inferior angle of the parietal, descends through the front part of the mastoid portion of the temporal, and thence on to its petrous portion, where it runs through the cavity of the tympanum, and ends at the spinous process of the sphenoid. The man was admitted into St. George's Hospital in July 1835, having fallen against a stone step during a scuffle in which he was engaged with one of his companions. He ultimately died of intracranial inflammation.

And in this third preparation (c) we shall now find the fracture confined to the posterior fossa of the base of the skull. Commencing at the torcular Herophili, the line of fracture passes perpendicularly down into the foramen magnum, where it ends. The patient was admitted into St. George's Hospital in July 1842, having fallen off a donkey, and struck the back of his head against the ground. He died of inflammation of the membranes of the brain, with secondary deposits in various parts of the body.

Some scattered observations of fractures thus strictly confined to these three different regions of the base, are to be found in various authors, but how and why these fractures are limited in certain cases was, as far as I know, first pointed out by Dr. Aran in the year 1844.

In his most able paper Dr. Aran (d) has clearly demonstrated the course which the line of fracture usually takes in these cases. In precipitating a large number of bodies from various heights on to the head, Dr. Aran found that the part of the vault which first struck the ground, gave, as it were, the key to the fracture which would take place at the base. Similar results were also obtained when diffused blows were dealt on the skull by means of a large and heavy hammer.

In the front part of the vault, injuries thus produced led to a fracture of the anterior fossa; in the middle part of the vault, they led to a fracture of the middle fossa; and, at the back of the head, to a fracture of the posterior fossa; in no single instance was a fracture detected at the base, without a line of fracture being traced down from the vault.

These experiments prove, then, that in injuries of the base of the skull, the line of fracture does not, in the great majority of cases, start from the base, but from the upper or lateral parts of the skull, and from thence stretches into the base. The line of fracture is, in fact, to be traced from the point of the vault at which the blow was struck right into the base.

Some years back, being desirous of testing the value of Dr. Aran's views on this important subject, I determined upon carefully analysing, during a series of years, every case of fractured skull which was examined after death at St. George's Hospital.

These investigations were spread over a period of ten years, during which time seventy-eight cases of fractured skull of various kinds were examined; in most of which the accident had been similar to that produced artificially by Dr. Aran. A fall from a great height, or a blow from some heavy instrument, having been, in a large majority of these cases, the cause of the fracture.

(To be continued.)

## A COURSE OF CLINICAL LECTURES

ON

## DISEASES OF THE KIDNEY.

By GEORGE JOHNSON, M.D. F.R.C.P.

Physician to King's College Hospital.

### LECTURE VII.

In my last lecture I gave you some particulars of a case of contracted Bright's kidney, or as we prefer to call it, *chronic desquamative disease of the kidney*, which ended in fatal coma. This mode of termination occurs in a very large proportion of the cases of this and other forms of Bright's disease; indeed so frequent and so intimate is the connexion between coma and renal disease, that it is of high practical importance to examine carefully the condition of the urine in every case of illness in which coma exists as a symptom.

It is the contracted Bright's kidney—the "gouty kidney," as Dr. Todd calls it—which more frequently than other forms of chronic renal disease gives rise to coma, or convulsions, or other formidable cerebral symptoms, and this particular form of disease is the one which more commonly than any other is overlooked by the Medical attendant. There are few diseases of any organ more insidious in their progress than this chronic desquamative disease of the kidney; few which oftener reach their last stage before their presence is suspected. I have told you before that those cases of chronic Bright's disease which are associated with enlargement of the kidney have a different clinical history from those which we are now considering. Practically one of the most important differences between the two classes of cases is this, that while, as a rule, dropsy is present, and forms a prominent symptom in the one, the other cases—those in which the kidneys are contracted—very commonly pass through all the stages of renal degeneration without the occurrence of dropsy in any form or degree. The existence of dropsy immediately suggests the probability of renal disease, the urine is examined, and the disease is discovered; but if in a case of threatening head symptoms dropsy forms no part of the patient's history, it not unfrequently happens that the investigation of the urine is neglected, and the true nature of the disease is overlooked, until its discovery is too late for the patient's safety, or the practitioner's credit.

I can give you an illustration of these remarks in the case of Louisa S., aged 52, who came in here on the 9th June, 1856. She was unable to give any account of herself, and we could obtain but a very imperfect history of her. I saw her a few hours after her admission, and I noted that she was rather a fat woman, that she was conscious, but very drowsy, and could say little more than "Yes" or "No" to our questions. The legs, arms, and face were constantly twitching in a manner somewhat like the subultus of typhus, or the contortions of a patient with chorea, but with the movements of the mouth there was a continual foaming, as of a patient in an epileptic fit. The skin was cool, the pulse only 60 in a minute; the tongue coated, but not dry. A systolic bellows sound was heard over the base of the heart. There was no dropsy. We learnt that she had been under the care of a very

(d) Arch. g n r. de M dec. 4th S rie, tom. vi.

intelligent practitioner, and that he attributed the twitchings to a mental influence produced by her having read the reports of the strychnia-operations of the notorious Palmer.

The peculiar twitching movements in this case immediately reminded me of the case of a man whom I had attended as a Dispensary patient some years ago, and who had very similar twitchings while he was dying with chronic Bright's disease, and I suspected that renal disease, with uræmia, might here again be the cause of the symptoms. She had passed no urine since her admission, nor could she pass any now, when the nurse urged her to do so. The House-Physician, Dr. Probert, then, at my request, introduced a catheter and drew off about six ounces of urine, which was clear and pale, moderately albuminous; specific gravity 1010. After standing some hours it deposited no sediment, and a microscopical examination discovered in it no tube-casts.

These being the facts of the case, what was the prognosis? Those of you who were in the ward when we were investigating the disease, will remember that I commented upon it to this effect:—The affection of the nervous and muscular system is, in all probability, the result of contamination of the blood, consequent on disease of the kidney. The renal disease is chronic, for in no form of acute disease with which I am acquainted would the urine have the characters which it has in this case. In particular the pale colour and transparency of the urine, and the small quantity of albumen, make it very unlikely that the disease is acute. On the other hand, the appearance of the urine, and its low density, together with the absence of dropsy, render it in the highest degree probable not only that the disease is chronic, but also that it is of the chronic desquamative form in an advanced stage; in other words, that it is a case of contracted Bright's kidney. If we could have found the granular tube-casts in the urine (see fig. 7 in previous lecture), we should be more certain as to this being the form of disease; but it has occurred to me before, to find that during the last few days of a patient's life the tube-casts, which have previously been very numerous, greatly diminish in number, and sometimes entirely disappear.

In the course of the evening the patient became comatose, and in less than twenty-four hours she died.

The kidneys were found reduced to about half their natural size, and contained numerous cysts. On microscopical examination they presented the appearances which are characteristic of this form of disease; the most important of these characters being a denuded condition of the uriniferous tubes, consequent on destruction of their epithelial lining. I have here under the microscope some specimens which illustrate these appearances, and you will find them fully described in my book on the "Kidney." I shall not now occupy your time by further details upon this point. I have only to add that, so far as we could ascertain, the brain was quite healthy, and that there was some atheromatous deposit near the bases of the aortic valves which may, perhaps, have produced the bellows-murmur before mentioned.

With reference to the muscular twitchings in this case, I would remark that the state of blood induced by Bright's disease of the kidney appears not unfrequently to have the effect of irritating the muscles. Patients who labour under this disease often suffer from cramp in the muscles. Muscular rheumatic pains, too, are often complained of. A short time since I attended, with Dr. Bright, a gentleman who, while he was recovering from a serious attack of acute renal disease, with numerous purulent tube casts in the urine, continued for several weeks to suffer from very severe muscular pains, which shifted often from one part to another, but more commonly had their seat in the muscles of the back. Counter-irritation, opiate embrocations, and warm baths, each in turn had some mitigating effect; but in the end, a course of Vichy water, taken at home, got the credit of dispersing the pains.

Dr. Inman, of Liverpool, who has lately published a very able and original treatise on "Spinal Irritation," would probably have said that the muscular pains in the case to which I have just now referred were simply the result of fatigue in muscles which had been weakened by a long and severe illness, and that the pains ceased only when the muscles recovered their normal tone and strength. The history of the case is quite consistent with this explanation, which may very likely be the true one.

Returning now to the cases which have come under our care here, you have seen that two patients, one spoken of to-

day, and one in my last lecture, have died comatose, and that in the brain there was found no structural change which would account for the coma. These are cases of what was formerly called *serous apoplexy*—the theory being, that the pressure of the small quantity of liquid which is commonly found in the ventricles and on the surface of the brain is the proximate cause of the coma. This theory is now abandoned, and the coma is, with more reason, attributed to the toxic influence of contaminated blood upon the brain.

There may, however, be another cause for the sudden coma which sometimes affects the subjects of Bright's disease. Not unfrequently these patients are seized with *sanguineous apoplexy*, an example of which has lately occurred in the case of James L., aged 45, who was admitted into No. 4 Ward on the 9th July. This man was a carpenter, of very intemperate habits, who during a period of nine years had had repeated attacks of gout; and we learnt from a friend who brought him to the Hospital that about seven months ago he had been seized with convulsions, for which he was bled. He recovered without paralysis, and after a few weeks returned to his work. Three months after that seizure he had another convulsive attack, which was followed by some degree of paralysis of the left (?) arm and leg. He again recovered sufficiently to resume his work; but on the 7th July he was brought home insensible, and remained in much the same condition until his admission here two days afterwards. He was then in a half-conscious state, and answered questions with great reluctance and difficulty; the left arm and leg were powerless, and the face was drawn to the right side; pupils natural; bowels costive; urine generally passed in bed, but some which was obtained for examination was found to be slightly albuminous, its sp. gr. was 1011, and it contained small waxy and granular casts. He was placed on milk diet with beef-tea, and was directed to have ten grains of compound gamboge pill, to be followed by a senna draught.

The bowels were moved by the medicine, the urine and feces were passed in bed, and he remained in the same half-conscious state until the 14th July, that is, five days after his admission, when he suddenly became quite insensible, and the left pupil was much contracted, the pulse was imperceptible, the breathing irregular, and in about an hour he died.

On examination of the brain after death, we found the right ventricle filled with blood, and the walls of the cavity softened and disorganized. The quantity of blood effused was at least two ounces. There was the remains of an apopleptic clot just external to the left optic thalamus, the brain substance around it having a yellow tinge.

The heart weighed 14½ ounces, the walls of the left ventricle were thick and firm; the valves were healthy. Both kidneys were small, their surface granular, the cortical substance thin. One weighed 4½ ounces, the other 4¼ ounces. They were in a comparatively early stage of chronic desquamative disease; the course of the disease and the patient's life having been cut short by cerebral hæmorrhage. It is evident from the history of the case, and from the post-mortem appearances, that blood had been effused into the brain on more than one occasion before the last copious hæmorrhage, which probably occurred only an hour before death.

Here then is an example of chronic Bright's disease, complicated with an effusion of blood into the brain; and I beg your attention to a brief statement of the circumstances which appear to render the subjects of that disease more than ordinarily liable to this fearful accident.

In the first place we commonly find that there is more or less disease of the coats of the blood-vessels in the bodies of those who have died of chronic Bright's disease. Atheromatous patches are often seen on the lining membrane of the large arteries; and even the minutest subdivisions of the vascular system—the smallest arteries and the capillaries—may be seen, on microscopical examination, to have their walls studded over with oil-globules. This evidence of degenerative change in the capillaries of the brain was first observed and described by Mr. Paget. My friend and colleague Mr. Hulke, submitted portions of the brain of our patient James L. to a microscopical examination, and found decided indications of structural degeneration in the minute vessels. Now without stopping to inquire into the cause of this association of degeneration of the walls of the blood-vessels with chronic Bright's disease it is obvious that the existence of such degeneration, affecting the blood-vessels of the brain, must be a predisposing cause

of cerebral hæmorrhage. The cohesion and the elasticity of the vessels are lessened by the structural change in their walls, and they are therefore more than ordinarily liable to be ruptured by the pressure of their contents.

But there is another fact in the morbid anatomy of these cases which must have an important share in the production of cerebral hæmorrhage. I need not now repeat what I told you in my last lecture, of the frequent co-existence of hypertrophy of the left ventricle of the heart with chronic disease of the kidney; the only probable cause for the hypertrophy in a large proportion of instances, as in the case which I just now related to you, being that the blood when contaminated by urinary excrement is retarded in its passage through the minute systemic vessels. It is obvious that this hypertrophy of the left ventricle is an additional element of danger in the cases to which I am now alluding; for consider the facts of the disease. The blood-vessels of the brain have their walls degenerated, and, as we believe, unnaturally fragile. There is an impediment to the flow of blood through the minute systemic vessels, calling for an increased effort on the part of the left ventricle, which consequently, growing up to its work, becomes unusually thick and strong. It appears, therefore, that an abnormally strong heart has to drive impure blood through resisting vessels with morbidly brittle walls; a concurrence of circumstances highly favourable to the rupture of the vessels, and the escape of their contents. It is no valid objection to this view of the effect of hypertrophy of the left ventricle to argue that the increased growth of the muscular tissue of the heart is only sufficient to overcome the impediment which has called it forth, and that the actual force and speed of the circulation are not thereby increased. For it is manifest that, supposing the impediment to exist in the capillaries, all that portion of the vascular system which intervenes between the heart and the minutest vessels which are the seat of obstruction, must be subjected to excessive strain and pressure, and in a corresponding degree to the risk of rupture.

Do not, I beseech you, look upon the question of the connexion between cerebral hæmorrhage, hypertrophy of the heart, and renal disease, as one of mere speculative pathology, with which the practical Physician has no concern. It is very important to recognise these facts in practice, not so much on account of any direct influence which a knowledge of them will exert on the treatment of disease, as with reference to their bearing upon prognosis. An attack of apoplexy supervening upon chronic disease of the kidney, is, *cæteris paribus*, a more formidable affection, more likely to be immediately fatal, or, if not so, yet more likely to quickly recur, than a similar attack uncomplicated with renal disease. The case of our patient, James L., who had three or four seizures within seven months, is an illustration of this statement. It is evident, therefore, that the interests of the patient and the credit of the practitioner alike require that these circumstances in the history of an apoplectic seizure should receive their due share of attention.

## ORIGINAL COMMUNICATIONS.

### THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.

Consulting Physician to the Hanwell Asylum.

#### No. 5.—MANIA AND CONVALESCENCE.

THE four illustrations of maniacal physiognomy already given in previous numbers have shown a few of the infinite modifications of facial expression in the human being. In the first, the profound reflection and the torturing conscience of the religious melancholic, covering this beautiful world with a veil of darkness, and tempting the victim to rush she knows not where; in the second, that dreadful condition of mind when all worldly hope has left it, and it is occupied with imaginary dangers, and with terrors unspeakable; in the third, the blank hopelessness and helplessness of imbecile old age, when all the long past years constitute but an unsatisfactory dream, and no fresh flowers, and no prospect nor hope of a second spring cheer the winter of the heart;—these are

representations of some of the mental trials incidental to the most highly gifted of the creatures of this globe. The fourth illustration showed how some of the forms of suffering may be, at different times, varied and interchanged in the same individual; in consequence of some morbid change in the relations of the senses or affections, or, perhaps, of the whole nervous system, with the impressions ever making upon it, and which in health it receives or responds to with salutary results to the body and the mind.

The reader who takes sufficient interest in these papers to refer again to the preceding one (No. 4), will find in the engraving very significant indications of such changes of feeling in the countenance of the patient whose portrait accompanies it. At first this was a case of puerperal mania, with a propensity to suicide. Melancholia succeeded to this stage, and after a time gave place to a return of maniacal excitement. The portrait represents the patient in the transition stage from sadness to renewed excitement. Although the melancholy traces of the form of her malady in its first stage have not wholly disappeared, new emotions have evidently risen up in the mind, and have modified the movements of the muscles of the face. The lines of care from the ale of the nose remain, and the chin and lower part of the cheek still retain the impress of depression; but the eyes have awakened from the gloomy sleep of the melancholic stage, and are bent energetically, even fiercely, on some real or imaginary object, near or distant. The forehead, still wrinkled, bespeaks aroused attention; and the general expression of the face is that of an angry sense of injury inflicted, and of some novel suspicions which menace violent actions. The patient, it will be remembered, was subjected to the photographer when mania was displacing the melancholia to which it had previously given way. There are many patients whose mental disorder, being incurable, presents these alternations several times in a year, and for all the remaining years of life. An unhappy man will pace up and down some chosen part of the ward of an Asylum, or of the gravel-walk of a garden, day after day, for many months, until the very earth and stones are worn; never speaking, never smiling; the personification of misery. But to this state may succeed a strangely-contrasted gaiety, lively talking, wild laughter, and the dance of merriment. Unhappy-looking women, who have sate from morning to night, week after week, the hands clasped and pressed on the breast; the eyes heedless of the passers by; and dependent on the help of attendants as respected dress, food, and every other care; pass from this moping condition to a state of gaiety which produces amusement even among their fellow-patients; unexpectedly making their appearance in some old and carefully preserved finery; their hair curled and ornamented; their whole deportment displaying the vanity of fancied beauty and of faded grace marvellously restored.

In some instances the alternations are even more extreme, the depressed state being accompanied with suicidal intentions, requiring much precaution; and the lively state passing into dangerous mania, in which the patient will try to break and destroy all surrounding objects, tear clothing to rags, and make sudden and violent attacks on any one within reach. The transformations occurring in this description of cases are extensive and curious. Every feature undergoes a change; the muscular system is either wholly excited or in a general repose; and the very hair seems to sympathise with the mysterious changes existing in the diseased nerves, being in one state lank, heavy, and hanging in heavy masses about the sorrowful visage, and in the other starting up wildly and in a picturesque fashion from the scalp, as if each particular hair did really stand on end with emotional excitement.

Some beautifully-executed plates appended to Esquirol's great work on "Mental Maladies" have been already alluded to, and woodcuts have been given of two of them, representing chronic oppression of the intellectual faculties, and a continued and insupportable grief. The eighth and ninth Plates in the same work present such remarkable illustrations of the variable expression of the faces of patients in different stages of mental disorder, that it has been thought desirable to insert woodcuts of them in the present number. Both plates represent the same patient: a young woman; the first in a state of acute mania, the second when a state of calmness, mingled with some degree of melancholia, had given assurance of her convalescence, and she was about to leave the Asylum. In the first plate the patient's countenance, and attitude, and

dress, almost relate her case—indicating high maniacal excitement, general moral commotion, a disposition to destroy or to

attack, and a mind occupied with irritating and tumultuous thoughts and images, excluding all consideration of external objects, and of the realities and duties and utilities of existence. Deep corrugations above the nose and inner angles of the eyes deform the youthful face; the cheeks are indented with lines of intense agitation; the mouth is compressed with anger and a kind of disdain, and the determined contour of the chin, the lower lip slightly up-gathered, is in harmony with the whole appearance of the disturbed maniac. The hair is itself in a kind of mad disorder; the trunk of the body, invested with a single garment, is pressed against the wall; the uncovered feet are gathered up on the bench on which the patient sits, as if preparatory to some sudden spring or action, and doubtless the arms would be in motion, if they were not fastened up in a camisole; a restraint considered necessary in the time of the good Esquiro, but which subsequent practice has proved to be unnecessary even in cases of this kind; which it is found better to leave in what seems a wild liberty, but yet so carefully looked after that the natural relief of strong muscular exertion can be permitted, with satisfaction to the patient, and without danger to others. The position of the patient in the figure would seem to indicate some resistance to the restraining dress, and there can be little doubt that her being thus bound would tend to confirm her prevalent delusion that she was to be murdered.

While contemplating this figure, indeed, there arise in the memory figures impressed there in former years, when close restraints were often capriciously imposed, and generally reluctantly removed. The rage usually ensuing in a patient violently tied up in them was intensely manifested by facial

distortion, and by all the outrage that the tongue could pour on all the persons of insane establishments: the body became heated and feverish, refreshing sleep was banished, nutrition impaired, and often deep local mischief induced. When in such cases restraints were, in the first days of such trials, experimentally removed, and removed all at once, the scene which ensued was often very touching. The outrageous words, and almost inconceivable execrations, then considered among the regular symptoms of mania, ceased in an instant; and the silence was only at length broken by sobs of surprise and gratitude, which the patient could command no words to express. The relief thus conferred never seemed to pass out of the patient's recollection; but was in some cases referred to, and often with renewed emotion, years after it had taken place.

The second wood-cut shows the young female patient, 20 years of age, who is seen in the first so wholly under the dominion of a paroxysm of mania, now restored to composure and to reason, and to intellectual and to moral life. All sign of passionate emotion has disappeared; the attitude is

that of rest and calm; the features of the face are placid, representing exhaustion and depression, but no anger, or disturbance, or suffering of any kind. The hair has submitted to control; the forehead is smooth, the eyes are pensive, the indentations of the cheeks are gone, the liberated arms and hands are crossed, and the whole figure expresses relief and satisfaction.

It is the recollection of such contrasts, every now and then revealed to the Physician in practice of this special description, which helps to sustain him when first appearances are

full of discouragement, and sometimes even revolting. He has seen them before, and seen them recede under the influence of medicinal and moral treatment, followed with discretion, and dictated and animated by the feelings of kindness which may be truly said to be generally characteristic of men engaged in the Medical Profession.

In the great movement that has taken place within the last quarter of a century in relation to the management of the insane, nothing has been more remarkable than the general anxiety of Medical men of all ranks to encourage every effort to produce amelioration. Their general character, indeed, confers honour on the Profession to which they belong. In the great social questions now occupying so many considerate minds and benevolent hearts, their services in the collection of facts, and suggesting improvements, are equally conspicuous.

If the general lot of medical men is but a life of labour and anxiety, of which advancing age and inactivity are the only limits, their minds are still, it may be observed, usually full of cheerful thoughts; for almost all their recollections are associated with some benefit, great or small, conferred on old and young, and on rich and poor, and on those pained in body, or those more pained in mind. Toiling through the streets of London, or of our large towns of never-ending struggle; or riding over hill and moor and marsh in the country, for their allotted period of some fifty years, in all seasons, in all weathers, and at all hours; strangers to social, and sometimes of necessity even to family comforts and enjoyments, these good men are in every town, and in many an out-of-the-way village, the centres of civilisation, the promoters of every improvement, the medium of communication between the scientific world and the ignorant; the founders of Hospitals, the gratuitous servants of Charities innumerable; and the perpetual intercessors between the rich and the poorest of the poor.

The student of medicine must pardon an old lecturer to the young, himself passing onward "to the river we must cross," for thus diverging into a kind of eulogy of a Profession to which they, as well as he himself belong. He feels confident that they will admit that the mere acquisition of knowledge would be of very limited value if it did not confer power for beneficial ends; and that our aspirations are, in this world, only redeemed from meanness by our ever preserving the great truth in our hearts that "Power to do good is the true and lawful end of ambition."

To this end let the student of medicine be assured that the study of the external characters, and even of the facial characters of disease, is neither trivial nor profitless. As respects mental disorders, to the outward characteristics of which these papers are particularly devoted, the facial expression and the general shape of the face and head will be found to impart important information, both as regarding the character of the affection itself and the probable event; guiding the practitioner in the prognosis, the subject of which is usually forced upon him by anxious relatives. It was evidently the intention of Esquirol, if longer life had been accorded to him, to prosecute this subject further (tom. ii. p. 167); and it is deeply to be regretted that the numerous drawings he had caused to be made with this object, and which are preserved, and doubtless interesting, should be rendered comparatively valueless by the want of references to the cases of the patients represented.

There are not a few persons who profess to consider what is called Physiognomy as a merely fanciful science, based only on the most striking departures from regularity of feature, or quiescence of expression. Some extravagances interspersed with the acuter observations in Lavater's great work on the subject, and the enthusiasm of his readers when it appeared, now more than sixty years since, and who professed, somewhat pedantically, to read characters in faces, but dwelling more on the bony shape than on the muscular expression, not only led to doubts concerning the accuracy of their general observation, but created a sort of distaste for a science which seemed a little too curious and presuming. People with odd-shaped eyes looked askance at the disciples of Lavater; and people with long noses or chins disliked having conclusions drawn from them. It requires, however, no argument to prove how much the character of the face has a general relation to the habits, and prevailing sentiments and passions. A great part of an actor's study and profession consists in the skilful representation of every variety of external manifestation of character except his own; and his

achievements well exemplify how large a meaning attaches itself to physiognomy; which, disregarding, as we may well do, the derivation of the term, really signifies the external manifestation of character in the face, the gestures, the mode of walking and speaking, and the dress. The popularity of caricature drawings rests wholly on the felicity with which the artist catches the broader oddities of mankind, in features and figure, and in their favourite costume; by which their whole character is often portrayed, without the necessity of verbal description.

## ON THE SURGICAL TREATMENT OF GLAUCOMA.

By J. W. HULKE, F.R.C.S.

Assistant-Surgeon to King's College Hospital; and Medical Tutor in King's College, London.

IN a paper read before the Royal Medical and Chirurgical Society on the 12th January of the present year, I communicated the results of the dissection of several eyes affected with glaucoma, which I had examined directly after their removal during the life of the patient. These notes on the morbid anatomy were accompanied by a description of the ophthalmoscopic signs, and by a brief summary of the symptoms of this disease. An abstract of this paper has already appeared in the *Medical Times and Gazette* of January 23rd, to which I would refer those who are anxious for further information on this subject. In the above paper I made frequent allusions to the writings of Dr. A. von Graefe, Professor of Ophthalmology in the University of Berlin, who has recently defined with great precision the true nature of the disease as distinguished from some other deep-seated affections of the eyeball, and has proposed on scientific grounds a plan of treating it, which already promises to be as successful in its results as it is masterly and original in conception. Mercury and the abstraction of blood are the chief measures which have been heretofore employed against this disease; and that these and other remedies have constantly failed, even in the hands of their most sanguine advocates, is so well known as hardly to need remark. Glaucoma has been one of the most intractable and hopeless of eye-diseases. It can hardly be wondered at, then, that when accounts reached us last spring that Dr. A. von Graefe was curing glaucoma by excising a portion of the iris, they were received with some degree of scepticism and incredulity. However, the communication which he made to the Ophthalmic Congress assembled at Brussels in September of last year, the facts which he stated in favour of his views, together with the remarkable success which attended his mode of treatment, all these confirmed and thoroughly established his position.

Dr. A. von Graefe has stated his views, and described his treatment of this disease in a Memoir addressed, in July or August last, to the Institute of France, and in an elaborate article in the second part of the third volume of the "*Archiv für Ophthalmologie*," edited by Professors Arlt, Donders, and himself, and published at Berlin, October 1857. It is very interesting to notice how he was brought, step by step, to the operation which finally gave him such success. How to lessen the excessive intra-ocular pressure was the leading idea which guided him; for he was convinced by the visible pulsation in the central artery of the retina, by the cupped state of the entrance of the optic nerve (both which he first described in this disease, of which he considers them pathognomonic), by the hardness of the eyeball, and by the other symptoms, that the tension of the globe was greatly increased, and he rightly ascribed the blindness which takes place so early in the acute form of the disease to the effects of pressure upon the retina and entrance of the optic nerve, rather than to any structural changes already taking place in these parts. How to diminish this augmented pressure, and so to restore the natural tension of the eyeball, was the problem he undertook to solve.

The whole class of evacuates, antiphlogistics, diaphoretics, diuretics, laxatives, and a mercurial course pushed even to salivation, had failed in his hands, just as had always happened to others; and this directed his attention to local measures. He first tried mydriatics, which he had found useful in the ciliary neurosis which attends corneitis and iritis; but here they

failed him, probably, as he says, because little or none of the atropine he dropped in was absorbed, in consequence of the internal distension. Then he tried the well-known operation of paracentesis of the anterior chamber, and with some abatement of the symptoms, but the melioration was only temporary; and even in cases where he had at intervals repeated the operation, the results obtained were not permanent. His own observations had already made him acquainted with the influence of the formation of an artificial pupil in certain cases of partial sclerotic and corneal staphyloma. The practice has been to remove the staphyloma, and then, if possible, to make an artificial pupil if the natural one was obstructed, but Dr. A. von Graefe has reversed this order: he had first made the artificial pupil, and then had found that the staphylomata sank to the common level. (A. F. O. Bd. iii. Abth. ii. 491.) Bearing this in mind, he experimented on animals, excising portions of the iris, and found the operation was followed by a softer state of the eyeball. Supported by these facts and conjectures, he thought himself justified in performing iridectomy in glaucoma. He performed his first operation in June 1856. The operation he recommends consists in the excision of a large portion (even a fifth or fourth) of the iris in its entire breadth from the edge of the pupil to the ciliary margin. Mr. Bowman does not (at least in chronic cases) excise more than an eighth of an inch, but, whatever the extent, he makes an excision of corresponding length at the edge of the sclerotic into the extreme rim of the anterior chamber, with a common extraction knife, great care being taken not to wound the iris or lens. So far the operation resembles that for extraction, only a very small flap is raised at the junction of the sclerotic and cornea, but rather in the sclerotic.

Dr. A. von Graefe recommends that the portion of iris to be excised should be larger in proportion to the intensity of the symptoms and distension of the globe. Mr. Bowman has observed that much care is necessary in making the incisions; the small size of the anterior chamber consequent on the advance of the lens demands great caution in directing the point of the knife; and if the chamber is opened by a simple puncture, which is subsequently enlarged by a sawing movement, the difficulties may be increased by the immediate escape of the aqueous humour, and the knife becoming entangled in the iris, or wounding the lens before the incision has been enlarged to the desired extent. The knife, therefore, once entered, should be pushed steadily but slowly onwards, so as to cut its way out ere the escape of the aqueous humour allows the iris to fall before its point or edge. When the incision is complete, the iris bulges a little through the margins of the wound; it should now be gently drawn out with forceps, and be cut off with scissors at each angle of the wound. The result is that the pupil is at once enlarged up to the incision, which forms, as it were, the base of a *coloboma iridis*, and the edge of the lens with its suspensory ligament passing in front of the vitreous humour to the ciliary processes is exposed to view; a little blood often trickles into the chamber, and may be either removed through the incision, or allowed to remain and be absorbed.

Dr. A. von Graefe usually makes the incision at the inner side of the cornea; he thinks the situation of little importance, but says it may, if desirable for appearance sake, be made above. This last situation was chosen, and is preferred by Mr. Bowman, because, while he considers it a matter of indifference as far as regards the relief of tensions which part is excised, he believes that the cover thus given by the upper lid to the margin of the lens, which has been exposed by the removal of the iris, contributes to the perfection of vision, the central part only of the lens being usually uncovered.

The operation was introduced into England by Mr. Bowman, and first performed by him in the Moorfields Ophthalmic Hospital, May 1, 1857.

Subsequently it was taken up by Mr. Critchett, and by other members of the Hospital staff. During the last six months it has been subjected to extensive trial, and, I may safely affirm, has succeeded beyond expectation. Mr. Critchett believing that a less extensive excision of the iris is sufficient has modified the operation; he makes a small incision within the margin of the cornea with a broad cutting needle, draws out a portion of the iris with a blunt hook, and leaves it in the wound; or if it protrude much, he removes a portion, and leaves the remainder in the wound. Entangled in the wound, it soon becomes adherent, and, after a few days

have passed by, the little bead of iris shrinks away, or remains for awhile as a small hernia.

The operation proposed by Dr. A. von Graefe is not very difficult to perform, and is not attended with subsequent inflammation; indeed, it may be undertaken, and often succeeds best during the active congestion of the acute form of glaucoma. The simplest treatment afterwards suffices; the lids should be closed for a few days with a small strip of plaster, and a piece of wet rag may be laid upon the eye if agreeable to the patient's sensations.

For a day or two after the operation the aqueous humour drains away, but soon the incision unites and the anterior chamber again fills. The hardness of the globe is at once lessened, and gradually diminishes till a natural tension is attained. The pain generally at once abates and soon altogether ceases; usually there is at once a slight improvement of vision, and this goes on steadily increasing for some time. The dulness of the cornea and the diffused haziness of the humour disappear, and, in many instances at least, the iris regains its natural brightness and its functions. I mention this latter fact particularly, because statements have appeared in print, that the iris becomes atrophied after the operation. The enlarged ciliary veins decrease, and soon the eyeball resumes a more natural appearance; indeed, the artificial coloboma is the only striking tell-tale which is left, and if the excision has been made under cover of the upper lid, even this is concealed from view. Coincident with these changes a similar improvement is going on in the deeper parts of the eyeball. The vitreous humour regains its clearness, and the ophthalmoscope shows us, that the pulsation of the central artery of the retina ceases; the retinal ecchymoses, which Dr. A. von Graefe says often increase immediately after the operation, undergo absorption in the course of a few weeks; and the turgid, dilated veins regain a natural size.

The improvement is most strongly marked in the acute cases, and the more early the operation the more successful is the result obtained. I have seen patients who previously had only a faint perception of large objects, afterwards able to read; and others who had merely a perception of lights and shadows have regained a most useful amount of vision. One very remarkable circumstance is the gradual increase of the visual field to its natural limits; patients have more than once remarked, "My sight is no longer so contracted."

In chronic glaucoma, the results are not so striking as in the acute form; nor need this surprise us, for the rapid blindness which occurs in the early stage of acute glaucoma is the direct effect of pressure upon the retina, rather than the consequence of structural changes; while in chronic glaucoma, structural changes in the retina proceed, *pari passu*, with gradual increase of pressure and the diminution of sight; yet, even in those cases of chronic glaucoma in which no obvious improvement has followed the operation, it appears to arrest the progress of the disease, and to preserve to the sufferer what little sight he has left. Future experience can alone determine whether the relief is permanent. A very important question is the expediency of performing the operation in the premonitory period, which, in about three-fourths of all the cases, precedes the more urgent symptoms. The difficulty of coming to a correct solution of this question will be increased in proportion as the early symptoms are vague; but when they are strongly marked, the known undeviating course of the disease will justify us in recommending the operation even at this early period.

I have hitherto abstained from entering into any speculations as to how excision of a portion of iris can reduce the over-tension of the eyeball; that it does so is an established fact, but the theory of the procedure is very far from clear. Dr. A. von Graefe himself conjectures that the reduction of the tension may be effected by a combination of circumstances, which comprehend the diminution of the secretory surface (of the iris), the relaxation of the tensor muscle of the choroid (ciliary muscle), and the influence which iridectomy exerts upon the circulation of the choroid.

The following we believe to be Mr. Bowman's views:—He supposes that the primary relief of the internal tension is due to the aqueous humour escaping at the time of the operation, and continuing to trickle through the puncture in diminishing quantity during the few days occupied by the healing process. During this first period the eyeball, he says, becomes more soft than natural, and the lens remains in contact, or nearly so, with the cornea. As the wound becomes firmly united,

the gap formed by the removal of the iris allows the aqueous and vitreous humour to come together (of course with the intervention of the delicate hyaloid and suspensory ligament), whereas the iris was before an effectual barrier between them, it being now clearly ascertained by the researches of Cræmer, Donders and others, that the iris is naturally applied closely to the surface of the lens, and admits no aqueous humour through the pupil—in fact, that no posterior chamber of the aqueous humour in reality exists. In glaucoma, the lens is usually forced forward, and the iris projected in front of it so as to be even more closely and firmly in contact with it than natural. Mr. Bowman conceives the result of excision of the iris probably to be, that the redundant fluid effused behind, and mingled with the vitreous humour, causing it to compress the retina, is permitted to transude into the aqueous humour, and then to escape from the eye either by exosmosis through the cornea (a road not previously open to it), or by being absorbed by the vessels distributed on the anterior surface of the iris. As this removal of the effused fluid gradually takes place, opportunity is given for progressive restoration of the aqueous humour in its natural quantity, and for the return of the lens and iris to their proper positions, while the globe acquires more firmness, without again becoming tense. As observed by Mr. Bowman, however, an eye thus treated is very apt to lose the power of adaptation to near vision, which it may have in some degree retained in chronic glaucoma up to the time of the operation: the exercise of this power depending on an increase of the curvature of the lens in the pupillary area under the pressure of the iris on its marginal region, an action which becomes almost, if not quite impossible, when part of the iris is excised. It thus, he says, may sometimes happen that an eye which is gradually and certainly losing all sight under the advancing disease, but which under favourable conditions, and with the aid of a convex glass, retains the faculty of reading even small print within a few degrees of the axis of vision, may lose some of this power by the operation, and nevertheless obtain a much wider range of sight, and secure that range permanently, by the subsidence of the morbid process consequent on the relief given to internal pressure. It is of course desirable in all cases, as pointed out by Dr. A. von Graefe, to excise as small a portion of the iris as shall suffice to secure the cessation of the disease. Future experience will probably serve to determine how much may be necessary for this, under the varying intensity of symptoms, and at different stages of its progress.

Another explanation has been offered by Mr. Critchett, who makes a smaller incision in the cornea, a little within its margin, and leaves the iris entangled in it, by which, he says, time is allowed for the adjustment of the normal tensions, and a sort of safety-valve is left for a time, to prevent such equilibrium from being again disturbed. (a)

Though all originality is due to Dr. A. von Graefe for the treatment of glaucoma by iridectomy, yet it is interesting to observe that the operation of paracentesis of the eyeball has been performed from very early ages; but such extreme difference of opinion has always prevailed as to the cases in which it is appropriate, and its value has been so variously estimated, that even to the present day the operation has never come into general use.

To go no farther back than Riverius, 1679, Jobus à Meekren, 1682, Antonius Nuck, 1696, we find the operation recommended, and designs are given for suitable instruments. The operation had been recommended in hypopyon, in onyx, in cases where blood was effused into the anterior chamber, and in dropsy of the eyeball; but great credit is due to Wardrop, who gave it an extensive trial, and first attempted to define the cases in which it was likely to prove useful. His observations are recorded in *Medico-Chirurgical Transactions*, vol. iv. 1813; he employed puncture of the cornea in cases both of superficial and of deep-seated inflammation of the eye, and with a view to lessen fulness and congestion.

Stimulated by Wardrop's success many other Surgeons, among whom I may mention the names of Langenbeck and Walther, warmly took up the operation, but their experience did not altogether tally with Wardrop's, and the operation again fell into disuse. In our own day paracentesis of the eyeball has been recommended by no one more strongly than

by Desmarres (b), who punctures the cornea more frequently than the sclerotica. For puncturing the cornea to let out the aqueous humour only, he prefers a needle with a shoulder or stop, which limits the distance to which the point can enter the anterior chamber (c); but he says if pus or lymph is to be evacuated, a larger incision should be made with a knife. For puncturing the sclerotica he employs a larger needle, also provided with a stop, and grooved; he plunges this instrument through the sclerotica, a few lines distant from the margin of the cornea, between the tendons of the lower and outer recti muscles; and if a portion of the vitreous humour does not flow readily away, he passes a probe or curette along the groove of the needle into the humour, and, by breaking up the hyaloid membrane, favours its escape. In this way he treats the inflammation which sometimes follows needle operations for cataract, and he also appears to employ it in deep-seated inflammation generally. When his object is to evacuate collections of fluid, as in sub-retinal dropsy, he pierces the sclerotica further back, to avoid wounding the lens. Among English Surgeons of our own day paracentesis has gained but little favour, though most persons have occasionally performed it. Mr. William Martin, Superintendent of the Calcutta Eye Infirmary, speaks highly of its beneficial action in fulness of the globe, with pain of a tensile character, and has recorded several cases in which he tried it with advantage (*Indian Annals of Medical Science, and Report of Cases*, etc. published Reigate, 1857). The frequency with which it often has to be repeated, and the temporary nature of the relief which it affords, constitute the chief objections to this operation.

## LACERATION OF THE DIAPHRAGM.

PROTRUSIONS OF THE ABDOMINAL VISCERA INTO THE CHEST—  
DEATH—EXAMINATION.

By VINCENT JACKSON, M.R.C.S.

Late House-Surgeon to University College Hospital.

Protrusions of the abdominal viscera into the chest arise generally from a solution of continuity in the diaphragm; the solution is either congenital or produced traumatically. Cases exemplifying the congenital variety have been reported by Sir Astley Cooper and others. The following case is an example of a protrusion arising from a lesion produced by external violence.

J. S., aged 71, was brought to University College Hospital, June 13, 1857. It appeared that early that morning the poor man was engaged in his work as a cleaner on the London and North Western Railway. He was described as standing behind the buffer of an engine, but leaning forward to clean some part of it, when suddenly two engines which were behind him were moved on, and the unfortunate deceased was jammed between them. He was immediately removed to the Hospital, but he died on the way. The breathing after the accident was described as having been short, quick, and catching, gasping every now and then.

*Post-mortem Examination.*—No marks of external injury. The chest below the nipple on the left side appears flattened.

*Chest.*—On removing the superficial structures it is found that the fifth and sixth ribs are broken; the fifth rib is not completely broken, being partly bent and partly fractured. The sternum is broken across transversely at a point corresponding to the fourth rib. On opening the chest the left lung is seen to be pushed up by some viscera of the abdomen, namely, stomach, spleen, transverse colon, and part of the small intestines; these have entered the chest through a rupture in the diaphragm. The viscera are easily withdrawn. The rupture of the diaphragm is considerable. Direction obliquely upwards and outwards; the tendinous, as well as the muscular portions being implicated in the fissure. The rent does not reach the middle line at the lower end, and it stops short of the wall of the thorax at its other termination. *Abdomen.*—The pelvic bones are separated at the symphysis pubis. The

(b) *Traité Théorique et Pratique des Maladies des Yeux*. Par L. A. Desmarres. Deuxième Edition, tom. iv. p. 28.

(c) Jobus à Meekren (*Observations Medico-Chirurgicales*, Amst. 1682, p. 97), gives designs of a lancet with a globular head, which prevents the lancet penetrating too deeply, because, he says, this cannot happen without injury to the lens.

(a) *Treatment of Acute Glaucoma*, by Mr. Critchett. *Ophthalmic Hospital Reports*, Jan. 1858, p. 59.

ligament that unites the bones in this position is ossified. Urethra not injured. *Left Thigh.*—Adductor muscles lacerated and discoloured with blood. No fracture of the bone.

The injuries received by a man at the patient's age were of that nature that almost immediate death followed. It was mentioned in the report that a "catch" in the breathing was noticed by the friends during the short time that he survived. This has been pointed out by Mr. Guthrie as a sign of diaphragmatic injury. These classes of injuries produced by the buffers of railway carriages, engines, etc., have been called "Buffer accidents;" the term is expressive enough, and is now become an addition to Surgical nomenclature. In the case detailed the rent was on the left side, and this, as far as observation goes, is the rule, but it has occurred on the right side. (d) There can be no doubt that the diaphragm was injured primarily by the external violence, and not secondarily by the broken ribs.

Sometimes the fractured ribs have occasioned the laceration. (e) In the Museum of University College a specimen—placed there by Mr. Quain—is preserved, showing the diaphragm ruptured on the left side, and portions of the stomach, colon, and omentum, with the spleen, in the left thoracic cavity. The fissure extends from the seventh rib obliquely inwards and downwards through the muscular and tendinous portions nearly to the spine. This also is an instance of the so-called "Buffer-accident."

## EXPERIMENTS AND OBSERVATIONS ON THE ACTION AND SOUNDS OF THE HEART.

By GEORGE B. HALFORD, M.D.

Lecturer on Anatomy, Grosvenor-place School of Medicine, &c.

(Concluded from p. 193.)

It would be impossible, within the limits of these papers, to criticise all the views that have been put forth in explanation of the cause or causes of the heart's sounds. Some of the opinions are well worthy of consideration, and can only be put aside by observation and experiments tending to their contradiction, —others are little else than fancies, directly opposed to known physical laws. The assigned causes, I believe, worthy of investigation are:

1st. Bruit musculaire; 2nd. Impulse of heart's apex against the ribs; 3rd. Rush of blood into and out of the heart's cavities.

1st. With respect to "bruit musculaire," if it and the first sound were identical phenomena resulting from the same cause, viz. muscular contraction, it would follow that in cases of hypertrophy of the heart, in which the cause is increased, the effect (the first sound) should be increased also; but the reverse is the fact; therefore, they are not identical phenomena.

Again, that they are not identical, is proved to demonstration by my last experiment, in which, although muscular action is going on vigorously, no sound whatever is heard. The explanation of the diminished sounds in hypertrophy is that the sounds being valvular, are less audible through thicker than through thinner ventricles.

Indeed, much, if not all, of what is usually put down as bruit musculaire is nothing more, in my opinion, than the vibrations of the compressed air in the tube of the stethoscope, or in the external auditory meatus, produced by the impulsion of the instrument or some other solid against the ear, or by friction between the two; for a low rumbling sound can be produced by pressing a handkerchief or the corner of the pillow against the ear, or by slightly pressing the tragus into the meatus, and another sharper sound is developed by its sudden disengagement on the removal of the finger. On this subject, the late Dr. Bellingham has a very good remark; speaking of the so-called bruit musculaire heard at night during the contraction of the masseter and temporal muscles, he says that it is only heard by the ear resting on the pillow, and not at all by the other; a fact I have frequently verified, and which is explicable only upon the supposition that the

sound results from the contact of the ear with the pillow. Now, all such adventitious sounds may be developed at the time of the ventricular contraction, or beat of the heart, and the more awkward the auscultator, the more are they likely to arise; but that the first sound of the heart is due to muscular contraction, and identical with "bruit musculaire," is, I think, logically and experimentally disproved.

2ndly. The striking of the heart's apex against the ribs has been given as a cause of the first sound. But since the apex is not tilted forward, and inasmuch as the blow is only apparent, and is the result of the noiseless change of form of the ventricles within the pericardium; and further, since the sounds are more audible after the walls of the chest have been removed than before, this, at first sight, probable cause, becomes, in fact, no cause at all.

3rdly. The passage of the blood into and out of the heart has been assigned as the cause of one or both sounds of the heart.

Several modifications of this cause have been entertained by different authors, as, for instance, "Shock of blood against the ventricular walls;" "Collision of blood against the orifice of the aorta and pulmonary artery;" "Concussion between the active and passive portions of blood;" "Rush of blood," etc. etc. etc.

One author's opinions only I shall examine at some length, for the value of one represents pretty nearly the value of the whole.

The opinions of the late Dr. O. B. Bellingham, of Dublin, it will suit my purpose best to criticise; first, because his work is of recent publication, and has, I believe, the confidence of a great portion of the Profession; and, secondly, because the views he there sets forth are diametrically opposed to the Valvular theory of the origin of the heart's sounds, which it is my present purpose to establish.

He says, "The first sound of the heart we know is synchronous with the ventricular systole; in this act the blood, compressed by the contraction of the powerful muscular walls of the ventricles, is propelled with considerable force into the aorta and pulmonary artery, the sigmoid and semilunar valves of which are suddenly elevated. In the rapid passage of blood from a wider to a narrower area, there must be considerable friction between this fluid and the parietes of the arterial orifices, quite sufficient, in my mind, to produce the prolonged first sound of the heart. This sound has necessarily a distinct character from the second sound of the heart, because the resistance to be overcome is so much greater, and the passage of blood through these orifices is more gradual; it is likewise more prolonged, because sound must be developed during the entire period that the blood is passing from the ventricles into the large arteries; and the slower the action of the heart the more prolonged will the sounds be."

To this I object, that it asserts nature to be at fault, which is impossible. There is no such disproportion (in health) between the orifices of the vessels and the cavities from which they spring; they are gradually continuous one into the other; the aorta and pulmonary artery, by virtue of their perfect elasticity, increasing in area as the capacity of the ventricles is diminished, as shown in fig. 2, page 110. There is not "considerable friction between the blood and the parietes of the arterial orifices," so long as vessels, valves, and ventricles remain healthy. When either the mobility of the valves or the elasticity of the arterial coats becomes impaired, then, I grant, sound may be, and constantly is produced. But what can exceed in smoothness the lining membrane of the heart and arteries? There cannot, then, be friction, which would presuppose an error in the mechanism; an exception in the Divine Author's works. Again, the heart has sufficient work to propel the blood to the distant capillaries, without meeting with obstructions at the instant of its effort. Lastly, where is the "friction between the fluid and the parietes of the arterial orifices" in Brakyn's experiment, and yet the first sound is heard, resulting from valvular tension alone?

Of the second sound he thus speaks:—"The second sound of the heart we know is synchronous with the ventricular diastole. During this act the muscular fibres of the ventricles are relaxed, the cavity of the ventricle enlarges, and the walls of the ventricles re-expand; the curtains of the auriculo-ventricular valves open, and there is a sudden influx of blood from the auricles through the auriculo-ventricular orifices. It is scarcely necessary to say that it is not the contraction of the auricles which propels the blood into the ventricles at

(d) Medical Records and Researches. A case is given by Mr. Bowles, Surgeon at Bristol.

(e) Medico-Chirurgical Transactions, vol. vi. p. 375.

this period of the heart's action; nor is the dilatation of the cavities of the ventricles the result of the entrance of blood from the auricles, as some have supposed. It is not, either, necessary for the production of this sound that the diastole of the ventricles should be an active process like the systole: the ventricles being hollow muscles, the state of relaxation of their muscular fibres is a state of dilatation of their cavities; hence a vacuum would be created in them if the auricles were not at this moment full of blood, ready to supply them; but as the latter had been filling during the whole period of the ventricular systole, this cannot happen, and the blood passes through the auriculo-ventricular orifices in a full and rapid stream, and with sufficient force to generate sound."

Let me request the reader to turn to the Analysis of the Heart's Action, page 111, and, with it before him, follow me attentively, while I prove the above as full of error as it is possible for so many lines to contain.

According to Bellingham, then, the second sound is produced by the rapid flow of blood from the auricles into the ventricles, and this blood is drawn into the ventricles by the force commonly called suction, owing to the state of relaxation of their fibres, which, he says, the ventricles being hollow muscles, is a state of dilatation of their cavities.

In the first place, I object to the term "hollow muscles," as likely to mislead and perplex; for the ventricles are never hollow during life, their inner surfaces being either in contact with each other or with the contained blood. Then, as to the state of relaxation of their fibres being the state of dilatation of their cavities, see how this is completely disproved by my last experiment, where, the blood being shut out of the heart's cavities, the heart continues, nevertheless, to act vigorously. Here no dilatation can take place; for how—when the flow of blood through the heart is stopped, and hence all force from within removed—can the ventricular walls expand, how can the ventricular cavities be dilated? It is a physical impossibility (tending to a vacuum); and yet the globular form of contraction and the lengthened form of relaxation are distinctly seen, but no dilatation can take place. The phenomena are as follow:—So soon as the ventricles have ceased their contraction, relaxation of their fibres commences. This occurs previous to the dilatation of their cavities, and must not be confounded with it; for relaxation of the muscular fibres of the ventricles has no more to do with dilatation of their cavities, or with the passage of blood into them, than relaxation of the fibres of the sphincter ani has to do with the expulsion of feces from the bowel; yet in both cases the same passive yielding state of the relaxed muscular fibre is necessary to complete the act. As the abdominal muscles, through the medium of the feces, dilate the sphincters, so do the auricles, through the medium of the blood, dilate the ventricles.

Again, the blood does not, as Bellingham says, pass at the time of the second sound in a full and rapid stream into the ventricles. If it were so, it would follow that, by the time the auricles next contracted, the ventricles, as well as they, would be full; in fact, there would be full auricles and full ventricles by the end of the diastole; and the next contraction of the auricles (which he admits, with every one else, immediately precedes that of the ventricles) would tend to arrest the systemic and pulmonary circulations, forcing the blood back into the *venæ cavæ* and lungs, for it is certain their force could not be exerted on the already distended ventricles; and it is also equally certain that the auriculo-ventricular valves could not act otherwise than to force back the blood flowing into the auricles upon the venous and pulmonary systems, seeing, as has before been shown (page 111), these structures form a perfect septum between the auricles and ventricles as soon as the latter become distended. In fact, such a heart as Bellingham describes we meet with when the ventriculo-arterial valves are so diseased as to permit of regurgitation; in such cases, the ventricles being imperfectly emptied, the auricles, which have their supply ready to inject into the ventricles, have part of the blood thrown back upon them, thence into the *venæ cavæ* and pulmonary veins, producing those distressing symptoms we are too well acquainted with.

Let us now hear Bellingham's objections to the valvular origin of the first sound. He says: "Now the first sound of the heart cannot have its cause exclusively in the sudden tension of the auriculo-ventricular valves, because this act takes place at the very commencement of the systole; and

the first sound is a dull prolonged sound, which persists during the entire systole."

As this same objection was made by the committee of the British Association appointed to discover the origin of the sounds of the heart, I cannot do better than answer it in the words of Bryan, when combating the conclusions arrived at by that learned body twenty years ago. On what grounds, he asks, is it stated that the cause of the first sound is of equal duration with the sound itself? The sound of a drum is of longer duration than the blow which caused it; a harp string vibrates long after the finger has struck it; and though the shock of the sudden tension of the ventricular valves be instantaneous, yet the vibrations excited by the shock of sudden tension may continue." To this I shall only add that the unequal lengths and sizes both of the flaps of the valves and of the chordæ tendinæ fully account for the prolongation of the sound.

I have thus shown that Bellingham's theory of the heart's sound is incompatible with the perfect action of the organ, and also that his objection to the theory of the valvular origin of the heart's sound is founded upon a total misapprehension of the subject, and consequently is of no worth whatever.

There is yet another road open by which inquirers may reach the truth, viz. post-mortem examination. I would suggest that careful notes be taken of cases of morbus cordis, and the sounds heard during life put side by side with the condition of the valves after death. The heart, however, should not be examined as is usually done; it should be tested hydraulically, as in fact it is during life, and then I feel certain we should soon arrive at a comprehension of all morbid sounds (bruits), and at a just estimation of their importance. Any London curator giving his attention to this subject, would assist the Profession materially. The following method I would recommend:—

Let the heart be removed with an inch or two of the large vessels, then cut away the auricles almost close down to the auriculo-ventricular openings, carefully take away the clot from the ventricles without injuring the delicate chordæ tendinæ. (a)

First shut down the semilunar valves with a stream of water, (the coronary arteries at their origin must be tied,) then pour water into the ventricles, and the valves, if healthy, will rise upon the surface of the fluid in proportion as the ventricles become filled, and form a perfect septum between them and the auricles. Should the semilunar valves be so diseased as not to permit of closure by fluid, the aorta or pulmonary artery, as the case may be, should be tied, or a cork inserted into it before the mitral or tricuspid valve is tested.

The above was the mode adopted by myself, others can of course use their own methods.

In conclusion, I would urge upon the student of medicine the necessity of thoroughly mastering the mechanism of the heart's action, the time and order of the occurrences constituting the rhythm. Only by so doing will he comprehend the morbid conditions he will be called upon to combat, and the sufferings he will be expected to alleviate. And to this end the table (page 111), was drawn up, and I hope will prove useful; and, as a starting point in the study of both functional and organic diseases of the heart, let the student adopt the following simple exposition of the healthy sounds, and all morbid sounds will quickly become intelligible to him.

When listening to the heart, two sounds are heard, the first long, the second short; they may be tolerably well imitated by the sounds *tub-duc*. When the first sound is heard the ventricles contract, and the auriculo-ventricular valves are made *tense*, and completely separate the cavities of the ventricles from the auricles; the *tension* of these valves produces the first sound. When the second sound is heard the ventricular systole has ceased, the aorta and pulmonary artery have reacted upon their contents; the cavities of the ventricles are separated from the systemic and pulmonary systems by the closure of the semilunar valves, the *tension* of which produces this sound. This is the true mechanism of the valves, and a sufficiently physical explanation of the origin of both sounds, none other, in my opinion, being reconcilable with the teachings of Natural Science.

17, Victoria-square.

(a) If even one of them b injured the perfect adaptation of the flaps of the valve is reversed.

## THE LONDON

## PRACTICE OF MEDICINE AND SURGERY.

## HOSPITAL NOTES.

## PECULIAR FORM OF UMBILICAL HERNIA.

We are indebted to Mr. Birtwhistle, House-Surgeon, for the following notes of this case:

William Tator, a child four months of age, was admitted into the London Hospital on Monday evening, the 8th inst., suffering from a peculiar form of umbilical hernia, the intestine being destitute of any covering whatsoever.

His mother stated that on the day of his admission in the morning she noticed a swelling at the navel about as large as a walnut, and consequently took him to her medical attendant, who reduced it, and put a bandage round the abdomen, which, towards evening, when looking to see if it remained properly adjusted, she was horrified on finding tilted up by a coil of intestine. She forthwith came to the hospital, when the hernia presented the following appearance: a portion of intestine (ilium) about fourteen inches in length, was protruded through the umbilicus; it was tense, strangulated, and highly congested, though still retaining its lustre. Reduction was found to be impracticable without first relieving the stricture, which object was accomplished by Mr. Luke, with the assistance of a director, and probe-pointed bistouri, when the gut was carefully replaced, and the wound (eight inches in length) closed by glover's suture; one drop of tr. opii was ordered, and to be repeated if necessary after two hours. The child died the following morning at about 10 o'clock.

*Post-mortem.*—The integument in the vicinity of the umbilicus presented no abnormal appearance to account for its having been thus ruptured by the intestine; there was a slight amount of peritoneal effusion, and the recently strangulated gut had not in the slightest degree recovered itself.

## FIBROID TUMOUR IN THE THIGH TWICE RECURRENT.

Amongst the examples of that interesting and rare class of tumours which are locally recurrent, but not, as regards the constitution, malignant, which have been reported in our pages during the last few years, was one in which a woman under Mr. Cock's care in Guy's had twice undergone the removal of a fibroid growth from the inner aspect of the left thigh. The first operation was in July 1856, and the recurrence was so rapid, that a second had to be performed for a growth very much larger than the original one in December of the same year. The second return took place almost before the wound had healed, and the growth was extremely rapid. The woman having meanwhile become pregnant, the performance of another operation was deferred. After her delivery she was again admitted under Mr. Cock's care, and in August last amputation of the limb near the great trochanter was performed. At this time the tumour had attained an enormous size, its girth being more than four feet. Ulceration had occurred, and the woman had been reduced to the last stage of debility by repeated hæmorrhages. Very little bleeding occurred during the operation; but the shock was so severely felt in the already exhausted state of system, that death followed eleven hours afterwards. No autopsy was permitted; but no reason existed for believing that internal deposits were present. No enlargement of the lymphatic glands had taken place. In asserting that the disease in such a case as this was not truly malignant, we of course use the word in a very conventional sense. The very rapid reproduction of these recurrent tumours and the speed of their growth are marked features in their history; and they certainly differ from cancers only in that neither the glands nor the internal organs are usually affected. But even the immunity of these latter seems to exist only so long as the growth is allowed its original nidus for development. Several cases seem to show that amputation of the affected limb does not rid the patient of the disease, but only renders him liable to its outbreak in some other part. Mr. Paget's observation, that these semi-malignant tumours are usually met with in the relatives of cancerous patients, is an important one. It is

quite evident that malignancy, like most other vices, is an attribute which may vary very greatly in degree.

## CAUTION AS TO THE DIAGNOSIS OF MALIGNANT DISEASE OF THE TESTICLE.

Two cases of much interest have recently been operated on in Guy's Hospital, which illustrate the difficulty in stating positively the character of certain enlargements of the testicle, and show the propriety of adopting exploratory steps previous to extirpation. In the first, a man, aged 88, was under Mr. Cock's care with an obscurely fluctuating tumour in the scrotum, of such character that most who saw it thought it medullary cancer. Mr. Cock, however, had his doubts as to whether it would prove to be merely an hæmatocoele with thickened walls, and accordingly laid it freely open before proceeding to extirpate. His suspicions proved correct, and the contents having been evacuated, and a free opening obtained, the cavity was left to granulate. The suppuration was for some time profuse, but the wound ultimately healed well. The second case illustrates the difficulty in diagnosis rather than the necessity for exploration. It is that of a man, aged 37, under Mr. Cooper Forster's care. He was pale and emaciated. The testicle was as large as a fist, and no one who saw it expressed any doubt as to its being cancerous. Excision was performed, and on examination afterwards the whole gland was found to be disorganised by the infiltration of tubercle, the epididymis also being involved. Had the true nature of the disease been known beforehand no other measure could have been adopted. That peculiar difficulties often attach to the discovery of an exact cause of enlargements of the testis, all Surgeons will admit. Mr. Paget is accustomed to observe in reference to the simulation of cancer by syphilitic and rheumatic sarcocele, that no testicle should be condemned as malignant until three remedies have been severally tried—mercury, iodine, and colchicum.

## DEATH FROM ANÆMIA.

The case under the care of Dr. Todd in King's College Hospital, which we mentioned on a former occasion as being suspected to afford an example of supra-renal capsular disease, has just ended fatally. No disease of the organs in question was found, nor indeed any important visceral lesion. The skin had only been discoloured in certain parts, and the degree of discoloration had varied from time to time. It had been most marked where a blister had been applied at a former period on the chest. Many who saw the case had, we understand, doubted much whether it was an example of supra-renal melasma. It will be recollected that the patient was deemed to have derived much benefit at one time from the free use of sugar. The early fatal event must be held to invalidate this conclusion, as far as regards the effect of sugar on idiopathic anæmia, while the discovery that the capsules were healthy, of course leaves the question of its usefulness in true supra-renal cachexia where it was.

## POPLITEAL ANEURISM CURED BY COMPRESSION IN TWENTY-SIX HOURS.

We are indebted to Mr. S. Cusack of Dublin for a report of a case of popliteal aneurism cured in Stevens's Hospital, Dublin, in twenty-six hours and a-half. The patient was aged 38, the aneurism of nine weeks' duration, the result of a blow, about the size of an orange. Compression of the artery in the groin stopped all pulsation in the tumour. The man was treated for three days with digitalis, low diet, and advised to take but little fluid. The following details are interesting. The intermitting pressure, the simple form in which it was applied, and the use of opium to secure a proper amount of sleep, should attract attention.

October 30, 8 p.m.—A leaden weight, of a conical shape, and weighing five pounds and a-half, having been placed on the femoral artery in the groin, it was found that there was scarcely any pulsation in the tumour, and that he could bear this amount of pressure without much inconvenience. The pressure in this case was effected throughout by means of a conical leaden weight, the lesser end of which, about the size of an ordinary tourniquet pad, was applied over two folds of soft leather to the artery. To keep the weight in position, and to direct the pressure, a stiff iron wire, which had been inserted into its greater end while the metal was melted, was passed through a ring fixed in a cradle, large enough to stand on either side of his pelvis. He was ordered

a draught containing twenty drops of the liquor morphinæ, and it was hoped that he would be able to sleep with the pressure on. He was unable to sleep, but kept the pressure steadily on, except for about two hours, until half-past seven the next morning, when it was removed, to allow him to sleep, having been on nine hours and a-half. At half-past nine, a.m. (Oct. 31), the weight was re-applied until nine, p.m., making in all twenty-one hours' pressure out of the twenty-five. The tumour had by this time become much more solid, and the anastomosing vessels on its surface remarkably distinct; the leg a little more oedematous than before; the foot kept warm by a water-bottle.

Nov. 1, 10½ a.m.—He has had a good night's rest. There is a small gland, just where the pressure had been applied, which is tender; this, however, could be drawn to one side with the integuments, and the pressure was re-applied, having been increased to eight pounds, so as to stop all appreciable pulsation in the tumour. At 4 p.m., on removing the weight, which had been on this occasion applied five and a half hours (making in all twenty-six and a half hours), it was found that the pulsation and bruit did not return. The limb was warm, and he had no pain anywhere; but the tumour felt hot and tender. He was directed to keep the pressure on for six hours longer, to make sure of a perfect cure. At 10 p.m. all pressure discontinued; "repeat morphia draught."

All went on well until the 15th, when the tumour had so far subsided that the patient could not be persuaded to remain in the Hospital any longer.

## Medical Times & Gazette.

SATURDAY, MARCH 27.

### PRINCIPLES AND PROSPECTS OF MEDICAL REFORM.

Now that "the battle of the Bills" is again about to be fought let us clearly understand what we are to fight for. Let us clearly understand what is meant by "Medical Reform." Let us as a Profession be of one mind regarding the PRINCIPLES at least on which a Medical Reform Bill ought to be framed, so that when the subject comes to develop itself in its executive details, sound and fundamental principles being adhered to, there may be no difficulty in administering not only the letter, but the spirit of such a Bill.

The three fundamental principles which Medical Reformers may agree to maintain have been well put in an able paper entitled, "Principles of Medical Reform," which has been extensively circulated during the present week among members of both Houses of Parliament, and various influential persons. The paper will be found entire in another column. The three principles are thus enunciated:—

"First. Every Medical Practitioner, who has once been declared qualified, should have the right of free practice throughout the United Kingdom, without hindrance from local jurisdictions.

"Second. The names of qualified Practitioners should be inscribed in a register, to enable the public to ascertain their qualifications, and to distinguish them from the unqualified.

"Third. Every Practitioner, whatever higher distinctions

he may attain, should be required to pass through one common examination."

If the Profession could agree to agitate for these principles, there can be little doubt, after what Lord Derby said last week, (see our Parliamentary Intelligence,) that the present Session might put an end to this long-voiced question, without the necessity for the ROYAL COMMISSION we have so long held up as a middle course. And as they are the principles so long and so perseveringly insisted on by Medical Reformers in general, and especially by the British Medical Association, it appeared probable that something like union was to be expected, and that we should not have a repetition of the misapprehensions of last Session, reminding one so strongly of the old rhyme,—

"Friends and foes, to battle they goes,  
But what they all fight for nobody knows."

But Mr. Cowper's Bill, as we shall see presently, has introduced a singular complication, and bids fair once more to throw us upon the COMMISSION. In the meantime let us consider for a moment the bearings of the three principles given above in all their breadth and comprehensiveness; not only upon those who are already entitled to be regarded as properly and legally qualified to practise medicine, but also upon those who may become so under the proposed measure.

The three principles mutually supplement each other; so that, as a whole, they constitute a broad and comprehensive measure of Medical Reform. They imply in their integrity such a constitution of the Medical Profession as shall secure to all its members a good preliminary and Professional education, with free and unrestricted right to practise throughout the British dominions; a constitution calculated to promote the advancement of Medical science, the respectability of the Profession, and the security of the Public. Equality of privilege has long been contended for; and while the desirableness of such a measure is conceded by all, it is only characteristic of our free Institutions which are at once the glory and the pride of the British people. The science of Medicine will not be impeded but promoted by free and uncontrolled licence to practise in any locality. Let equality, then, of Professional rights be the first article in this Bill.

The names of qualified Practitioners being recorded in an authorized register, will at once show who are legally qualified practitioners and who are not; and make known the honorary distinctions they may ultimately possess, such as "Fellow of the Royal Society," "Fellow or Member of the College of Physicians," "Fellow, Licentiate, or Member of the College of Surgeons," "Doctor of Civil Law of any University," "Doctor of Medicine of any University." The Government Register under the Act would be the only legal record of the fitness of any man to practise medicine, or to hold any public appointment where medicine in any of its branches is practised, to give medical evidence in a court of justice, or to sign any medical certificate required in the daily practice of the healing art.

The question of registration affects two parties—namely, medical men already possessing qualifications, and those who would become qualified after the passing of the Act. With the latter there is no difficulty. So soon as they pass the necessary examination required by the Act, let them be simply registered by Government as "Licentiates in Medicine and Surgery," fitted to pursue any department of their profession, or to avail themselves of the best opportunities to practise in any part of the United Kingdom. This list would embrace that large body of Medical Practitioners who at present have neither a common feeling nor sympathy with any vested rights of Corporation or University; who, except that they had once derived a legal right to practise from some of them, are unconnected with these bodies. While such a register would doubtless be the lowest qualification, it would be,

at the same time, both a legal and a secure one for the public. The appearance of a name in it would be a guarantee to the very poorest man that he can obtain the attendance of a properly qualified Medical practitioner—one who has passed through a fair, uniform, and sufficient education. The Governmental record of such fair, uniform, and sufficient qualification could not, of course, prevent a man from seeking eminence in the higher walks of science or of literature. On the contrary, the higher grades of the Profession would still find that in such a register a column would be reserved for them in which to record the honours they may have attained in Societies, Colleges, or Universities. These institutions would remain unfettered in their modes of elevating their standards of qualification for those honours they are entitled to bestow. Such institutions will thus be left to fight their way by healthy competition and dignified emulation. The scientific position of all will tend to elevation by such wholesome competition, the powers of all to do good will be greatly extended, and new charters to these learned bodies may still more enhance the good they are able to effect, in accordance with the liberal spirit of this age of progress. It is true, a slight difficulty in registration meets us at the threshold; but we think it is to be easily got over. It is the question as to how we are to dispose of the various qualifications of the Medical men now practising, so as to admit them into the Government Register as simple "licentiates in Medicine and Surgery." At present it is a fact that "no existing body confers a complete licence for general practice;" and therefore we think that such a mutual concession ought to be made, that all who at present hold a qualification from any body having at present the legal right to confer it ought to be registered *simpliciter* in the Government Register as "a licentiate in Medicine and Surgery."

So much for the second article for which we contend, namely, one Government Register of the legally qualified. In Mr. Cowper's Bill the first and second of those principles are admitted. The third is the battle-ground. In place of the one State Examination, all the existing licensing bodies are to go on as at present. The constitution of the Council is also materially different in the two Bills; but we must reserve for next week a summary of the points of agreement and difference. Lord Elcho's Bill is down for the second reading on the 12th of April, and Mr. Cowper's on the 23rd; but as the first is low on the list, it may probably not come on, and Mr. Cowper's may be the first on which a debate can arise.

Let us, then, consider the third article, namely, the "one portal" through which all ought to be required to pass. It is only by this means that the Legislature will be able efficiently to provide for the security of the public; by regulating the courses and the modes of instruction and the tests of proficiency. The tendency of the competition which at present exists among the licensing bodies is that of deterioration. It is a state of things which fosters a "competition downwards;" and it is only the pressure from without which keeps them up to the level *merely of mediocrity*. No doubt some of the licensing bodies have and do attempt faithfully to discharge their duties. Others again are more remiss, in order that they may draw to themselves a greater number of candidates for their "licence." So soon as that is effected, the more praiseworthy institutions are forced to relax their exactions and become remiss in their turn. Nay, it were not difficult to convince any one that the rigour of some examinations, though *visa voce*, written and prolonged, are more terrible in name and appearance than in reality, and therefore not efficient as practical methods of examining.

It were surely, therefore, preferable to establish one fair, uniform, and sufficient examination through which the Profession should be entered than maintain the present deteriorating system. Such a fair, uniform, and efficient test of

Professional acquirements contains the principle of wholesome competition in an upward direction. While all must enter by a common door, all may start fair in the race of life and step by step may rise upwards from this common level in Medical acquirements. The highest honours which Universities, Colleges, and learned Societies can bestow would be still open to all, would be no less diligently sought and honourably contended for. A still further stimulant to contend for such honours will be found in the fact that private Institutions and Hospitals would no doubt continue to select their candidates for office, as heretofore, from those who possess the highest attainments in science. Competition in the Medical Profession would thus be fostered, and not repressed; the Corporations and Universities would not be interfered with; they would be permitted to acquire an honourable independence; and thus they would at once be put in the position of Scientific Institutions. Competition, both as regards individuals and Medical Institutions, would be put upon a much more wholesome footing; and few will remain at the dead level of the simple qualification of "Licentiate in Medicine and Surgery" whose intellectual attainments are able to raise him higher. Hitherto the competition for honorary distinctions has been most strenuous; and the ardour would not be diminished by the fact that all must pass into the course through one common entrance.

The Bill which has now been read a first time by Lord Elcho in the House of Commons, is the Bill of the Select Committee of 1856, presided over by Mr. Cowper. Of this Bill it is to be said that no Medical Bill ever before arrived at so advanced a stage as to be reported upon *unanimously* by a Select Committee. Moreover, it is the only Bill we have yet seen which comprehends the *three great principles* we have just considered; and we think Lord Elcho does wisely in adhering to the exact form of the Bill in which it left the Select Committee of 1856, leaving any change that may be considered desirable in the executive details of the Bill a subject for consideration in Committee of the House. We have, therefore, purposely avoided saying anything about the constitution of the Council, because it is essentially a question of executive detail, not to be compared in importance, nor to be allowed to take precedence of those great principles we have noticed. Let us, therefore, be careful not to shift our ground; but on these three articles the Profession should stand firm in the fight for Medical Reform. The successful issue of such a fight would no doubt affect the individual interests of some; but who ever heard of a decisive fight in which one of the combatants did not yield? To be efficient, the conflict must be a decisive one. Some privileges had better be relinquished for the public good before they are altogether wrested from their possessors by the pressure of public opinion and the influence of social progress. It will always be found impossible to reconcile what is irreconcilable; and it is hopeless ever to expect the consent of all the various bodies whose interests will no doubt be affected in working out the executive details of an efficient and comprehensive measure of Medical Reform. To the justness and goodness, therefore, of the measures we have here advocated we look for success through a liberal and enlightened Legislature.

#### THE WEEK.

Lord Campbell gave a judgment at Warwick, on Monday, of considerable interest to scientific men likely to be called upon to give evidence in Courts of Justice. "A scientific witness having asked his opinion as to whether he was bound to attend upon being served with a subpoena, he would say that a scientific witness was not bound to attend, and ought not to be subpoenaed. If he knew any question of *fact*, he might be compelled to attend, but Her Majesty's subjects were not compellable to give their attendance to speak upon matters

of opinion." This should be jotted down among the things which should be, but are not, generally known.

Mr. Wiblin of Southampton has applied to us to allow subscriptions to be received at the office of this Journal for the benefit of the widow of the late Dr. Rolph of Portsmouth. We accede most willingly to Mr. Wiblin's request, and trust that his benevolent exertions may be followed by complete success. Dr. Rolph, it may be remembered (see *Medical Times and Gazette*, November 21, 1857), had the misfortune to attend in a case of adherent placenta. A portion came away, and he judged it better to leave the remainder, and wait for the natural action of the uterus, than to exert a degree of violence he thought likely to be dangerous in separating the adherent portion. The woman died, not of hæmorrhage, not of peritonitis, not of pyæmia, but of a form of low fever prevailing in the neighbourhood. An inquest was held. The jury agreed to a most damaging verdict. Under the instigation of enemies this verdict was engraved on the tombstone of the woman. Dr. Rolph saw it, and he died of a broken heart. All those who, like our departed brother, are exposed to the danger of being held criminally responsible for the misadventure of losing a patient after exerting their best efforts in her behalf, have now the opportunity afforded them of showing their sympathy with the widow he has left unprovided for.

Mr. E. Touch, Assistant-Surgeon of the 83rd Regiment, has earned his promotion to the rank of Surgeon by the display of such military ability as many Medical officers undoubtedly possess, but are not often called upon to exercise. It is well known that during the weary trench work in the Crimea, the influence of the medical officers was very great in maintaining the discipline and endurance of the men; so, lately in India when the mutiny broke out at Aboo, Mr. Touch was the only officer present able to take command. In this emergency he led on his men in the most gallant manner, and took such vigorous measures, that the mutineers, who outnumbered his men by three to one, were completely routed, and the lives of all the Europeans in the place and the hospital were saved. Mr. Touch was constantly in the saddle for three days. Surely the Victoria Cross would be well bestowed upon such an Army Surgeon as this.

The annual meeting of the Cork Medical Protective Association was held last week at the Royal Cork Institution, when a large and influential body of Medical gentlemen assembled together under the presidency of Dr. Harvey. From the cordiality and unanimity which prevailed among the members of the Association, and from their correct appreciation of the evils which now afflict the Profession, we may anticipate that much benefit will accrue to the interests of our Medical brethren in Ireland and throughout the empire. One very excellent feature in their proceedings, and one worthy of imitation in our own country, was the system pursued during the last general election, of demanding from all candidates for seats in Parliament a distinct pledge that they would protect the interests of the Medical Profession. The Association, it appears, determined to support only those candidates who consented to give such a pledge, and disregarded all political considerations in comparison with the urgent claims which Medicine now possesses on the attention of the Legislature. The chief point of interest at the late meeting at Cork was the sympathy expressed for the Dispensary Medical officers in Ireland, who appear to be exposed to the same tyranny, caprice, and parsimony, at the hands of Poor-law Guardians, as the Poor-law Medical officers are in Eng-

land and Wales. Dr. McCarthy of Kenmare, who, it will be recollected, was subjected to the indignity and injustice, last autumn, of having his miserable salary reduced by the Guardians of his district, and to whose eloquent speech on that occasion we drew attention in our columns, delivered another most able and animated address before his Medical friends at Cork. He stated very truly, that although the Kenmare Guardians and the Irish Poor-law Board had succeeded in cutting off £20 a-year from his salary, yet the perpetration of this pitiful act of meanness and injustice had awakened a spirit of indignation throughout Ireland which would not soon be allayed, and had drawn more and more closely together the members of the Profession in defence of their common interests and rights. He also proposed a resolution that, in the opinion of the meeting, the minimum salary for Workhouse and Dispensary Medical officers should be £100 a-year; and he suggested, moreover, that the Profession should combine together in the determination to accept nothing less,—a sentiment which was most cordially applauded by the meeting. If any Medical man, after this general declaration of opinion, should accept a smaller sum, "then," said Dr. McCarthy, "we have the remedy in our own hands. Exclude him from the society of gentlemen, let him not be met in consultation." We are most happy to record the proceedings of the Cork Medical Protective Association, and we hope that the example set by the Irish members of our Profession in that large city and its surrounding district will be followed by the establishment of similar Associations in all the great cities of the United Kingdom.

M. Chevallier declares that in France at the present time phosphorus is the most dangerous form of poison known, having replaced arsenic, which is now so difficult to obtain, while there are less certain antidotes known for phosphorus than for any other poison. He has collected references to 86 cases of poisoning by phosphorus, of which number 21 arose accidentally, 25 were from suicidal intention, and 40 from criminal poisoning. Of these 86 cases, in 51 chemical matches supplied the phosphorus employed; and it is found that these cases are on the increase, just as cases of poisoning by arsenic are on the decrease. M. Chevallier also feels convinced that of late years a fourth at least, if not a third, of the fires that have occurred have been caused by these matches, whether from their careless employment, or from peculiar causes having given rise to their inflammation. He therefore calls upon the authorities to interdict all matches that are not fabricated with amorphous phosphorus, which, while they are innocuous to life and property, do not give rise in their manufacture to disease of the jaw among the employees.

The following advertisement is copied from the *Caledonian Mercury* of the 17th inst. :—

"MR. SYME'S CASE OF CANCER OF TONGUE.

The Medical Profession are recommended to read Dr. Renton's unanswerable Letter in the *Medical Times and Gazette* of March 13, page 278,—

AND

To corroborate Dr. Renton's Statements, *Medicus, junr.*, submits the following extracts to the Profession :

The late Mr. Miller, Fellow of the Royal College of Surgeons, in his 'Inquiry into the average Mortality in Lithotomy Cases,' thus observes :—"Mr. Syme, with his usual candour, takes no notice of the event; the reader is led into the belief that this was a successful case, the operator (Mr. Syme) being at the same time aware that the patient was dead."

Professor Miller, in a controversy with Professor Syme, in the *Edinburgh Medical Journal* of May 1851, states :—"I make no comment further than to observe, that should Mr. Syme explain

terms deny the occurrence of the serious evils thus maintained by those best acquainted with the facts to have followed his operation in this particular case, I fear some allowance must in future be made in reading his statements, regarding the other patients, in whose treatment no unpleasant consequences are said to have occurred.'"

What a pity it is, as this life is so short, that our Edinburgh friends should waste so much time in quarreling!

The annual festival of the Medical Benevolent College at the Freemasons' Tavern, on Wednesday, passed off remarkably well notwithstanding the absence of Lord Stanley. His place was well filled by Sir Charles Locock, who in a simple, manly, unaffected, but warm-hearted speech, advocated with such good effect the cause of the Charity that upwards of £1200 were added to the funds.

William Baldwin, the "chemist and man-midwife" of Maidstone, has been sentenced to one year's imprisonment, having been found guilty of gross ignorance in his treatment of a midwifery case. The particulars of this case have been given and so fully commented on in these columns, that we need do little more than refer to it as a proof of the absolute necessity of a Government register of qualified Medical men—not to prevent the public from employing whom they please, but to enable them to distinguish between the men who are authorized to practise, and the ignorant pretenders who are not. The uneducated must be protected by the educated from the dangers they are exposed to from unprincipled pretenders to Medical knowledge. Another case at Shrewsbury strikingly illustrates the necessity for such protection. A man named Lacey, who "having been a gas-fitter and soda-water and blacking manufacturer, had taken upon himself the practice of Physic," treated a case of pneumonia with some powders, which an analysis of the contents of the stomach after the sudden death of the patient showed to be "Indian tobacco." The prisoner had treated the deceased for inflammation of the liver and stomach, and the judge, Mr. Baron Channell, said that "if it could not be proved that the prisoner had been guilty of gross ignorance or of gross negligence in his treatment of the deceased, he was entitled to be acquitted." The jury then found him Not guilty, and he was discharged! So that if an inspired gas-fitter chooses to treat patients with "great care and attention," and cannot be proved to be guilty of gross ignorance or gross negligence, the law cannot interfere.

## PRINCIPLES OF MEDICAL REFORM.

In approaching the question of Medical Reform, it is necessary that we should have clear notions of what it is that calls for amendment.

During the past quarter of a century three Select Committees of the House of Commons have considered the subject, and numerous bills have been brought into that House. Some of these bills have chiefly aimed at imposing penalties upon unqualified practitioners, quacks, and systems of unorthodox medicine; the right, however, which is asserted by every free-born Briton to indulge in medical as well as theological heresies, renders it vain to attempt to establish faith in any system by Act of Parliament. Other bills have attempted to define the boundaries of the different orders of the Profession, viz. of Physicians, Surgeons, and General Practitioners; but the tendency of society, as well as of the Profession, being towards a fusion of these orders—Physicians being daily found practising as General Practitioners, Surgeons as Physicians, and General Practitioners both as Physicians and Surgeons—it would be futile to attempt by legis-

lation to mark out boundaries which neither the Profession nor the public are prepared to respect. Bills have also been framed with the object of reforming the constitution of the various Corporations of Physicians, Surgeons, and Apothecaries throughout the United Kingdom, and also of effecting reforms in the system of conferring degrees in some of the Universities. Legislation in this direction would be very desirable; but the diverse constitutions of the bodies to be dealt with, and the conflicting interests involved, must render this an extremely difficult, if not an absolutely hopeless, task.

What Parliament, as the guardian of the public interests, have chiefly to consider is, the relation which should subsist between the Profession and the community to whose necessities it ministers. Viewed in this light, there are three requirements which specially call for legislative recognition, and which should form the basis of a Medical Bill.

First. Every Medical Practitioner, who has once been declared qualified, should have the right of free practice throughout the United Kingdom, without hindrance from local jurisdictions.

Second. The names of qualified Practitioners should be inscribed in a Register, to enable the public to ascertain their qualifications, and to distinguish them from the unqualified.

Third. Every Practitioner, whatever higher distinctions he may attain, should be required to pass through one common examination.

In regard to the first of these requirements, it may be observed that, in the present state of the law, persons legally qualified to practise in one of the three kingdoms are prohibited from practising in either of the other two, and that even persons legally authorized to practise in one part of such kingdom have no legal right to practise in another part of it.

EXAMPLES 1. No Irish or Scotch Physician, Surgeon, or General Practitioner is legally qualified to practise in England, unless he submit to be re-examined and pay fees to some corporate body in England—and *vice versa*.

2. Graduates of Oxford, Cambridge, and London, have legal authority to practise throughout England, except within London and seven miles round; but within this boundary they cannot legally practise until they have been re-examined, and have paid fees to the London College of Physicians.

3. In Ireland, the legal right to practise as a Physician or Surgeon in Dublin and seven miles round, and also eligibility to certain public appointments in the provinces, are confined to members of the Dublin College of Physicians and Surgeons.

4. An Army or Navy Physician or Surgeon is not legally qualified to practise as a civilian, until he has been re-examined by, and has paid fees to, some Medical body of the kingdom in which he proposes to practise.

The exigencies of society have broken through many of these absurd impediments, but, nevertheless, most of them continue in sufficient force to prove petty annoyances in the hands of rival practitioners, inconveniences to the public, and obstacles to the admission of highly qualified men to public appointments.

It cannot be questioned by disinterested and unprejudiced minds, that it is most desirable to sweep away the *débris* of antiquated barriers to the right of free practice throughout the United Kingdom, so far as regards all persons who are properly qualified.

Little needs to be said in regard to the second requirement, —the institution of a Medical Register. Without limiting the free agency of any one, it is very desirable that the public should have an authorized list to refer to, in order to ascertain whether a practitioner is legally qualified or not, and what his qualifications are. Further, it will scarcely be considered an unreasonable concession to Medical men that they should have some public and official record in which to set forth their titles to public confidence.

At this point some Medical Reformers would stop short, and deprecate any further legislative interference. It will not, however, be possible to secure all that the interests of the public require, without having regard to the third requirement, viz. the one common examination,—and for the following reasons:—

There are about twenty different bodies—Universities and Medical Corporations—in the United Kingdom which confer qualifications to practise. Even with the present impediments to free practice, there exists a rivalry among them which is not favourable to the attainment of a high average standard

of proficiency. Among them are some which, at the risk of diminishing the number of applicants for their qualification, demand, both in general and professional knowledge, a high degree of proficiency; but, unfortunately, there are others which, deterred by the apprehension of being underbitten by each other, and thereby incurring loss of fees, are either slow or unwilling to make their examinations as searching as they ought to be, and therefore, it is apprehended that, if the obstacles to free practice are removed, without due provision being made for securing a fair standard of proficiency, increased facilities will only be afforded for carrying on the injurious competition. The heads of the Army, Navy, and East India Company have long since become sensible of this evil, and have instituted examinations of their own, through which all must pass who seek to gain admission to the public services. Why, may it be asked, should the necessities of civil life be less worthy of attention than the requirements of the public services? What is needed, therefore, is, that some Central Body or Medical Council should be instituted to establish a sufficient course of study and examination, through which, as through a common portal, all persons must pass who seek to be enrolled in the Register. The object is not to prevent persons from aspiring to additional distinctions, such as the degree of a University, or the diploma of a Medical Corporation: on the contrary, it is hoped and believed that the educational status of the whole body of the Profession being raised, and the competition downwards put an end to, the great bulk of the rising generation of Medical men will become ambitious of enrolling themselves as members of such Universities and Medical Corporations as will confer additional privilege and distinction upon them.

Meanwhile the Medical Corporations, like most other corporations, resist all legislative interference, unless on the condition that they shall be constituted the sole licensing authorities; and, as may be expected, the Universities, though assentient to the institution of an independent Medical Council, and common-portal examination, are unwilling to be put in a subordinate relation to the Corporations to which they attribute, and not without reason, the persistence in a low standard of education, and the fostering of ill-will by tenacious efforts to maintain local jurisdictions. All prospect of such an agreement between the Universities and Medical Corporations as would be conducive to the real interests of the Profession and the public being hopeless, the institution of an independent Medical Council becomes indispensable. The question remains, however, as to what should be the constitution of the Council. Regarding this there has been so much discussion as to threaten to entirely obscure the main question. Strong objections have been raised to Crown appointments to the Council, based upon the apprehension that it might give rise to jobbing. To remove these objections, it has been proposed that the Council should consist of representatives of the Universities and Medical Corporations. The objections to this proposition are various:—

1. Such representatives would likely prove mere delegates of the bodies which deputed them.

2. It would not be easy to indicate the proper persons in these bodies respectively who should elect the representatives. In the case of the Universities they might be chosen for the most part by non-medical men. In the case of some of the Corporations the electors might be too limited in number: for instance, the Master and two Wardens would be the electors in behalf of the London Society of Apothecaries.

3. Though such Representatives might represent the numerically small bodies by which they were elected, they would in no sense represent the Profession, which is for the most part linked by the weakest possible tie to either the Universities or Medical Corporations.

The only mode by which the Medical Council could be made in reality representative of the Profession, would be to commit the election to the whole body of Medical men in the United Kingdom: but a scheme which would devolve the appointment of persons to such an important executive body as the Medical Council to twenty thousand or more practitioners distributed over Great Britain is open to objections which are too evident to need to be enlarged upon. There seems, therefore, no alternative but to fall back on the system of Crown appointment; and considering that it has never been contemplated that the Medical Council should assume any government over the Profession, that it never was intended that it should supersede the existing Medical bodies, but that it should be

simply interposed between them and the public as the only available means of securing a sufficient, and at the same time a uniform, standard of qualification, it may be reasonably doubted whether any better mode of appointment could be devised, especially as it is proposed that the Council should be presided over by a member of the Government, and the whole of its proceedings laid annually before Parliament.

## MR. COWPER'S NEW MEDICAL BILL.

THIS measure has been prepared by the Board of Health, and, but for the change of Government, would have been brought in by the President of the Board. The principal features of the proposed bill are the following:—

"1. The present legally constituted examining bodies in England, Scotland, and Ireland respectively, to be re-enacted as the 'Examining Authority' under the Act for England, Scotland, and Ireland respectively; not to be touched in their several rights of giving titles of honour; but their certificates, if purporting to confer any claim to registration as 'legally qualified practitioner,' to be subject to regulation as under:—

"2. A Council to be established, as nearly as may be, representative of all interests concerned, taking as a basis (but subject to modification in detail) Mr. Headlam's proposal, that it should consist of 17 delegates from the different examining bodies, with 6 members appointed by the Crown.

"3. The Council to have the right of attendance by its members or by deputy at any examination held for the purposes of the Act.

"4. The Council to have power, after due public notice, and with the approval of Her Majesty in Council, to make orders and regulations as follows:—

"A. As to the form of keeping the general register and such special registers as may be kept; and as to the payment of registration fee by admitted candidates.

"B. Fixing, in respect of age, study, knowledge, and examination, the conditions under which the future candidate shall be admissible to the Medical profession as a qualified Medical practitioner.

"C. Determining, in respect of the several Examining Boards of the United Kingdom, what share may be fulfilled by the certificate of each of them acting separately, or by the certificate of two or more of them acting conjointly, as contributory to the total certification which shall give admission to the register.

"D. Disallowing the future certificates of any Board which shall conduct its examinations inefficiently or irregularly.

"E. Establishing, or causing to be established, examination in particular branches of knowledge, professional or preliminary, where arrangements for such examination shall not have been otherwise sufficiently provided.

"5. The Council to have power to disregister persons convicted of crime or guilty of infamous conduct in any professional capacity.

"6. The register and its titles to be protected from falsification; and non-registered persons to be excluded from professional privileges.

"7. Every registered person to be entitled to practise according to his qualifications in any part of the United Kingdom."

## REVIEWS.

*Human Histology, in its relations to Descriptive Anatomy, Physiology, and Pathology.* By E. R. PRASLER, A.M. M.D. &c. &c. Philadelphia and London. 8vo. Pp. 616.

THE aim of this work is—1. To give a connected view of the simple chemical elements, of the immediate principles, the simple structural elements, and the proper tissues entering into the composition of the fluids and the solids of the human body. 2. To associate with the structural elements and their tissues their function while in health, and the changes they undergo in disease.

This appears to have been the first work on Histology, or

the minute anatomy of the tissues, which has issued from the American press. It is well written, amply illustrated with excellent woodcuts, well known to those familiar with the writings of those men in Germany, France, and Britain who have done the most for this department of science. In some places only the source of these woodcuts is stated, but not in all. Quekett, Goodsir, Bennett, Todd, Bowman, Paget, Kölliker, Wedl, Lebert, are thus freely, and too often without acknowledgment, laid under contribution. As a compilation of the most consistent and recent information on histology, in its relation to physiology and pathology, the work before us must prove a useful one for the student. Organic chemistry and microscopic anatomy have now contributed to science such a vast accumulation of facts, often of a most isolated nature, that the labour of arranging them, and of condensing the results to which a study of them in a classified and systematic manner naturally leads, is a labour of no ordinary kind.

In the work before us, however, there is not only abundant evidence of such labour, but there is also evidence of much painstaking industry. The importance of accurate and extensive information on the subject of histology in all its bearings cannot be over-estimated; for now the science of Medicine may be said to be in a transition state, through the revelations of microscopy and chemistry. Without an accurate acquaintance with the most minute structural elements of tissue, in their purely anatomical as well as chemical relations, a profound knowledge of physiology and of the nature of disease, especially as taught by morbid anatomy, becomes impossible. This work, therefore, giving, as it does, a clear and condensed view of the state of our knowledge on histology, will prove of great value to the student of anatomy and physiology.

The work consists of two parts:—Part I. contains an account of the simple elements, and of the immediate principles of the tissues and the fluids. The topics in this part are treated of under the general title of *STÆCHIOLOGY*, from *σταῖχος*, an element. Under this term is comprised the classification and description of the simple chemical elements; and of the immediate principles which enter into the composition of the tissues and fluids of which the human body is composed. In the first division of this part, the simple chemical elements entering into the structure of the human body, are stated shortly: while the second division treats of the immediate principles of which the tissues of the human body are composed. Here the nature of "Immediate principles" of organised bodies is well described, the study of which is "intermediate between mere organic chemistry on the one hand, and histology on the other," and must take precedence of the latter. A convenient classification of these "Immediate principles" is followed by a tersely given description of each in groups. In this division, the researches of Robin and Verdel, Burdach, Lehmann, Denis, and other eminent chemists are chiefly drawn upon and with due acknowledgment. An interesting and instructive section treats of the immediate principles of organic origin, formed within the body by what Dr. Peaslee terms "dis-assimilation"—a word which implies the same as the terms "waste" or "metamorphosis" of the tissues. The immediate principles of this class are sometimes termed "Secondary organic compounds," and the pathological bearings of the study of their formation and accumulation or retention in the system is of the utmost importance in appreciating the nature of *Constitutional diseases*.

Part II. treats of human *Histology* embracing under this title a scientific classification and description of the structural (morphological or organised) elements of the solids and fluids of living organisms. It includes also "*Histogeny*," or the development of these elements.

The topics in this part of the work are considered in three divisions, namely:—First, a description of their simple histological elements, their distribution, development, uses, and morbid states. Secondly, a description of the fluids of the human body (*Hygiology*) which contain histological elements. Under the third division, the tissues properly so called are classified and described.

Our limited space will not permit a full analysis of this part of the work, but there are several chapters and passages we have marked off as particularly deserving of perusal, and which we can only indicate, namely:—Chapter iv. on "Cytology," and the chapters on "Areolar Tissue." As an example of the concise and "to-the-point" mode in which Dr. Peaslee deals with his subject, we quote the following passage, and

recommend the book with confidence to the Profession, and especially to the student of Physiology and Pathology.

"Much discussion has arisen, of late, in regard to the value of the microscope in the diagnosis of cancer: one party contending that this instrument is totally unreliable in this respect, while the opposite (party) would rely upon it alone. The following is believed to be the only tenable view of this subject:—

"1. In all cases of *well developed* cancerous formation, the microscope in the hands of one *skilled in its use*, will alone demonstrate the true character of the growth, unaided by any knowledge of its appearance to the naked eye, of its tactile properties, or of the history of the case. This it will do by detecting one or more of the peculiar form of cell or nucleus already described. Here, therefore, the diagnosis may be positively expressed in the affirmative.

"2. But there are all possible grades of development, from the encephaloid, as the most strongly pronounced form of cancer, to the fibrous cancer, and onward to the simple, innocent sarcoma. There will, therefore, be a corresponding shading off of the peculiarities of the minute cancer elements (cells, nuclei, &c.) into the normal elements of true tissues. Besides, when cancer cells are still young, they do not present the peculiarities before mentioned. (Note.—"*All pathological newly-formed cells have no especial character peculiar to them.*"—Wedl, p. 66.) In the imperfect or early development of cancer, therefore, the cancer cell may so nearly resemble the fibro-plastic or some other cell that a microscopic discrimination is impossible. Here, then, the microscopic diagnosis must be guarded, and the history of the case and the other sensible properties of the growth must decide.

"3. The cancer elements may exist in small amount in masses supposed to be cancerous, and in the midst of a variety of other minute elements, and therefore escape detection. If so the microscopic diagnosis is *inferentially* negative, but not unqualifiedly so. The unaided eye, the sense of touch, and the history of the case may, however, together, decide the diagnosis *unqualifiedly*, either in the affirmative or the negative.

"4. In cases of well-developed cancer, therefore, the microscope, since it alone may decide the diagnosis, is in the highest degree reliable. In the other two cases mentioned it is less reliable than the other means alluded to; but here also it may prove of the highest value, by confirming or opposing the diagnosis suggested by them. It is the absurd assumption that the microscope can decide in every possible case, which has brought the instrument into disrepute. It merely enables us to see what would be invisible without it; and gives, so far as the minute elements are concerned, an advantage over those who refuse to use it, like that which one who has perfect sight enjoys in respect to things visible to the naked eye, as compared with the purblind. But as the unaided sight alone is almost never expected to decide, in case of suspected cancer, without regard to the tactile properties and the history of the case, so the sight, when aided by the microscope—for it is mere sight still—must not, except in a single class of cases, be relied upon alone. In these it should be recognised as an *arbiter* in the diagnosis of cancer; in all other cases it is merely a valuable aid."—P. 144.

*Gleet: its Pathology and Treatment.* By HENRY DICK, M.D. M.R.C.S. Pp. 88. London: 1858.

It is well known that a gleet, which is always the result of gonorrhoea, may continue for a very long period without causing much inconvenience; but that under certain exciting causes, independent of fresh contagion, a new gonorrhoea may be established. Dr. Dick enters at length into the symptoms, diagnosis, and prognosis of the discharge to which the term gleet has been applied; and in the treatment of this tedious affection he recommends, after other means have failed, the introduction of bougies, and the division of any thickening, or new-formed tissue which may exist in the canal of the urethra, originating and keeping up the gleet discharge.

*A Treatise on Electricity, in Theory and Practice.* By A. DE LA RIVE. Translated by C. V. WALKER, F.R.S. Vol. III. 8vo. Pp. 818. London: 1858.

THE present volume of this standard work is especially in-

teresting to the Medical Profession, as it contains important chapters on the production of electricity in physiological actions, atmospheric electricity, and the chemical, physiological, and therapeutic applications of electricity. About a hundred pages are devoted to a general view of the application of electricity to the art of healing, and descriptive of the apparatus employed, with an analysis of the direct and indirect therapeutic effects of electricity, an examination of particular cases to which electricity is applicable, and the physiological effects of atmospheric electricity. In this part of the work, Duchenne's work on localised electrization, and Becquerel's on the application of electricity to therapeutics, are critically analysed. There is an Appendix, containing a summary of new researches; and we think the author has quite succeeded in his endeavour to make his work "as much as possible parallel with the state of science at the end of 1857."

*The History and Design of the Foundling Hospital; with a Memoir of the Founder.* By JOHN BROWNLOW, Secretary of the Hospital. Pp. 144. London: 1858.

THE numerous visitors to the Foundling Hospital, and even the casual passenger who surveys the building as he walks along Guildford-street, will be interested in learning the history of this long-established institution. Mr. Brownlow has done good service to the public in presenting them with this little book, which contains a succinct statement of the progressive advances made by the Foundling Hospital, from its opening in 1741 down to the present time. The mode of admitting candidates has been altered from time to time, and great difficulties have always existed as to the selection of the proper objects; but the admissions are now entirely under the control of the Governors, who, we believe, exercise the trust reposed in them with discretion and impartiality.

*A Catechism of the Physiology and Philosophy of Body, Sense, and Mind. For use in Schools and Colleges, and in private study.* By T. WHARTON JONES, F.R.S. Pp. 124. London: 1858.

THE object of this little work appears to be to present the leading principles of physiology and psychology in a popular form to the mind. The plan adopted is that of a series of questions and answers, being the form most appropriate for the instruction of beginners. It will be readily admitted that a knowledge of the functions of the human body, and of the operations of the human mind, ought to form a part of all education, and the introduction of such information into our schools and colleges is certainly most desirable. In the work before us the leading truths of physiology are lucidly explained, and the well-known talents and reputation of Mr. Wharton Jones render it unnecessary for us to say more than that he has executed his task in a manner worthy of his distinguished position as a scientific writer.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### OBSERVATIONS ON HÆMOPTYSIS.

By Professor TROUSSEAU.

THESE observations by Professor Trousseau chiefly relate to the diagnostical and prognostical value of hæmoptysis. He observes that on finding an individual spitting blood, the first idea that presents itself is the existence of pulmonary tubercle; but if we note all the cases that present themselves, not in private but in hospital practice, we shall find the hæmoptysis as often dependent upon other causes as upon tubercular disease. This statement, paradoxical as it may seem, is quite true when confined to hospital patients.

A form of hæmoptysis that is rarely met with in hospitals is due to hæmorrhagic deviations. We meet with women who, without suffering from any notable disturbance of menstruation, but who are the subjects of nervous symptoms, spit blood frequently in considerable quantity. Neither the sym-

ptoms nor attentive exploration of the chest, indicate any affection of the heart or lungs; and when the period of menopause arrives the hæmoptysis becomes arrested, and does not return. Other women spit blood during pregnancy or lactation, and cease doing so when these conditions are terminated. These nervous women are also sometimes the subject of menorrhagia, seeming to be under the influence of a hæmorrhagic diathesis; and when the critical discharge does not take place by the uterine mucous membrane, it does so by the bronchial membrane. Although these hæmoptyses are not of the importance that might be supposed, and may be reproduced at longer or shorter intervals during several years, it must be borne in mind that this frequent repetition may induce a congested state of the respiratory apparatus, during which even a slight accessory cause may give rise to a more or less dangerous phlegmasia. Independently of abnormal circumstances, we may meet with hæmoptysis occurring, so to speak, as a physiological accident, supplying the place of a natural or accidental discharge of blood, which from some cause or other does not take place by the ordinary channel. Thus, in women with obstructed menstruation, it is one of the most frequent forms of hæmorrhage supplementary to menstruation. It will be readily understood that when with this peculiar disposition of the economy there is combined another dependent upon a local predisposing condition of the pulmonary apparatus, these hæmoptyses are still more readily produced. Under such circumstances the prognosis of hæmoptysis is far more serious than when it arises from hæmorrhagic deviations unconnected with local occasional causes. Here, in fact, the accidents become complicated with the local lesion which has led to these manifestations, just as this itself is necessarily complicated by the fact of the fluxionary hæmorrhagic movement, which at each return accelerates the evolution of such lesion.

As already observed, these varieties of pulmonary hæmorrhage are rare in hospital practice. The form of the affection, however, there most commonly met with is not hæmoptysis dependent upon phthisis, but hæmoptysis dependent upon disease of the heart. It is not meant by this to declare in an absolute manner that tubercular hæmoptysis is of rarer occurrence than hæmoptysis dependent upon disease of the heart, but only to state that in phthisis, hæmoptysis being in general a transitory condition, occurring early in the affection, the patients do not come to the hospital, while hæmoptysis dependent upon heart disease occurs principally when the disease is much advanced, and, consequently, at the period when patients are obliged to resort to the hospitals. Proceeding to consider some of the points of diagnosis between these two forms, we find that in youth, adolescence, and the early period of mature life, from the sixteenth to the fortieth year, hæmoptysis most generally is dependent upon pulmonary tubercle, and that whether it is met with in hospital or private practice; but after the fortieth year, and still more after the fiftieth, it is no longer, generally at least, a sign of phthisis, but of disease of the heart. There are exceptions to this rule, but they do not invalidate its general truth. In phthisis bloody expectoration may either precede any other manifestation of the disease, of which it may then be considered the earliest symptom, or it may appear in the course of the affection. Laennec indicated its slight quantity as a characteristic, and regarded very abundant hæmoptysis as almost always due to pulmonary apoplexy. But he had little opportunity of observation in private practice. It is true that in general hæmoptysis is not abundant, but still there are cases in which it is overwhelmingly so, causing death by the sole fact of the loss of an enormous quantity of blood. Hæmoptysis, consequent on disease of the heart, is, notwithstanding, still seldomer overwhelming (*foudroyante*) than bronchial hæmorrhage. It may recur fifteen, twenty, forty, or fifty days in succession without at once proving fatal. Of course, when dependent upon the rupture of an aneurismatic vessel into the bronchi, it may prove still more rapidly fatal than hæmoptysis supervening on phthisis. Besides the age of the patient and the progress of the symptoms as elements in the differential diagnosis, there is an important point in regard to the seat of the hæmorrhage, viz., that while in phthisis it takes place generally at the bronchial surface, in disease of the heart it is most often parenchymatous, first occurring in the pulmonary vesicles.

As to the question of the characteristics of bronchial and pulmonary sanguineous expectoration, it is said that bron-

chial hæmorrhage is observed under the form of spumous, semi-fluid sputa, resembling blood beat up with air, and having a bright redness, deemed characteristic. The quantity discharged is said to be sometimes very slight, and sometimes very abundant, not being mingled with the débris of alimentary substances or mucosities. But this is far from being always the case, as the sputa may be as viscous as those seen in the first stage of pneumonia, or in pulmonary apoplexy, an appearance, probably, due to slight accompanying inflammatory action, or to the accumulation and detention of the blood in the lungs. So, too, we may find the discharges mixed with alimentary substances when the hæmoptysis is undoubtedly connected with phthisis. Stethoscopic signs are often at default, or indicate as much, or even more, the pulmonary lesion upon which the hæmoptysis depends. Generally at the autopsy of persons who have been the subjects of bronchial hæmorrhage, we only find, besides the lesions proper to phthisis, redness of the pulmonary mucous membrane, which, indeed, may be due to imbibition. If cavities exist, they may contain a certain amount of coagulated blood, and that usually when vascular ruptures take place within these, otherwise we only find a little blood accumulated in the bronchi.

With respect to pulmonary hæmorrhage, we may advert to the erroneous term, "pulmonary apoplexy," which has been bestowed upon it, giving, as it does, no idea of the nature of the affection. It occurs in general during the course of an affection of the heart; and at the autopsy kernels of engorgement are found of as deep a colour as the spleen, and as hard as those of pneumonia in its second stage. The tissue of the lung is friable, and presents the granular aspect of hepatized tissue, except that while in the latter the vessels and lobular intersections are visible, the hæmoptical engorgement presents a uniform blackish, or very deep brown colour. This lesion, which would be better termed sanguineous infiltration, bears no analogy to cerebral apoplexy, the term apoplexy always implying the idea of suddenness and active fluxion, a condition rather belonging to bronchial than pulmonary hæmorrhage, which is ordinarily, to a certain extent, passive. There are, indeed, cases of true pulmonary apoplexy giving rise to sudden death, and characterized by the effusion of more or less blood amidst the lacerated lung. The term apoplexy would be much better applied to cases of active congestion of the lung, a not very rare disease, but which is rarely accompanied by hæmoptysis, properly so called. Gendrin proposes to substitute for the term pulmonary apoplexy, *pneumo-hæmorrhage*, indicating without ambiguity an extravasation of blood into the tissue of the lungs. As to the distinctive signs in these cases of pulmonary sanguineous infiltration, the expectoration is generally viscous, sometimes red, and sometimes black, and even deep black. But as in bronchial hæmorrhage the blood discharged is also sometimes black, so in the pulmonary it is sometimes spumous, and that especially when it is quickly and abundantly discharged.

While lesions of the heart are the usual causes of pulmonary hæmorrhage, contraction and insufficiency of the mitral valve is the most common of these lesions, and especially when, as is commonly the case, it is conjoined with ventricular hypertrophy. These hæmorrhages are sometimes very considerable, and may recur three, four, six, eight, or ten times in the course of the disease of the heart at other times, though rarely they are slight and transitory, and do not reappear. When the lesion is much advanced, the patients may spit blood for one or two months, and sometimes until their death. The disposition of these hæmorrhages is, in fact, to increase in frequency and in quantity with the disease of the heart, an effect of which they are, approaches its fatal termination.—*Union Méd.* 1857, Nos. 110 and 113.

#### CURIOUS CASE OF HEREDITARY DEFORMITY.

By M. SCOUTETTEN.

M. Scoutetten believes that the following is an unique example of a deformity, arising from an accidental cause, being transmitted through three successive generations, with a possibility of still further transmission.

A mason, of the name of Frache, aged 25, of regular conformation, fell from a scaffold, and severely injured his hands and feet. His son, Louis Frache, was born with a single finger on each hand, and two toes (the large and little ones) on each foot. He was a weaver, and a skilful operative. Louis had five children, four of whom were deformed, three

dying early. The eldest was well formed, and served in the army. He married and had one child who was normally formed. The second child, Margaret, having similar deformities to her father, married Linglemann, mason's labourer, aged 42, of robust health and good bodily form. Four children resulted—1. Louis Linglemann, 17 years of age when seen by M. Scoutetten, healthy and of natural formation; 2. Christopher L., aged 7, the feet have only the large and the little toes, and the hands only the medius and ring finger—these two fingers being in the right hand united as far as the first articulation, and in the left hand united throughout their whole length; 3. Catherine L., aged 5, the feet present exactly the same deformity; the right hand has three fingers, the index and the medius being entirely wanting. The left hand has only the thumb and the auricular, and on the last phalanx of the thumb is a projection indicating the abortion of a supernumerary finger; 4. Adele L., a little rickety girl, 18 months old, has only the two toes on each foot. The right hand has two fingers and a phalanx of the ring finger, the thumb and the index being entirely absent. The left hand has only the auricular and the first phalanx of the index. As to the mother herself, her feet are horribly deformed, having but two toes, curved inwards like the claws of a crab, like which, too, they move horizontally, pinching objects forcibly. The right hand has only the index finger, while the left has the auricular and ring fingers, united throughout their entire length.

Thus we have here three generations presenting deformities of the hands and feet, apparently originating in injuries to these parts which occurred to the great grandfather. And among the singular facts of the history are to be noted that the eldest son of Louis Frache, and the eldest son of Margaret Linglemann were both of normal configuration. This hereditary transmission of a deformity arising from a traumatic lesion is not to be confounded with vices of conformation, such as hypospodias, supernumerary fingers, or diseases transmitted from parent to child by a natural analogy of organisation, but which in nowise recognise an accident as their primary cause.—*Moniteur des Hôp.* 1857, No. 141.

#### NEW INSTRUMENT.

#### ON A NEW TROCHAR FOR PARACENTESIS THORACIS.

By CHARLES ROBERT THOMPSON, Esq.

ALTHOUGH there exists considerable difference of opinion as to the amount and nature of the risk incurred by the admission of air into the pleural cavity in performing paracentesis, there can be no question that it is desirable to avoid such an accident, as being never beneficial, and often productive of bad results.

With this view several instruments have been from time to time invented; but there has been a want of simplicity, or a doubtful efficiency in them; so that many surgeons still use the ordinary trochar, trusting to such a clumsy expedient as putting a finger over the orifice, during inspirations, to keep out the air, or leaving it to enter freely at the latter part of the operation.

The instrument which I have now to describe, will, I believe, fulfil the required conditions.

It consists of a cylindrical silver canula, about four inches long, and of the diameter generally used for this operation; into which opens, at near its middle, a short silver conducting tube of the same calibre, to which a piece of india-rubber tubing, about a foot long, is attached by a screw. In this canula plays a solid steel piston, with a trochar point; its body being of such length that when fully pushed forward (as in Fig. 1) its point protrudes sufficiently from the canula, and its other extremity seals the entrance of the conducting tube; and when fully withdrawn (as in Fig. 2) it retires so far as to open the conducting tube. This piston must fit the

canula so perfectly as to be air-tight when greased. The little cap of the canula unscrews, to admit of the removal of the piston for greasing or cleaning. The outer half of the canula is mounted in a solid wooden handle, to give a firm grasp of the instrument.

The mode of using it is as follows:—

Having well greased the piston, draw it back (as in Fig. 2) and, placing the end of the elastic tube into a basin of water, withdraw the air from it by suction at the end of the canula, and when the water reaches the lips push forward the piston. The elastic tube is now filled with water, which cannot escape, and the instrument is ready for use. When it is plunged into the chest, pull back the piston so as to open the conducting tube; when the fluid follows, and directly it meets the water in the tube, a syphon is formed. The end of the tube should be kept under fluid during the operation. If it is required to stop the flow, either during a fit of coughing or to change the receiving vessel, it can be done instantaneously by just advancing the piston sufficiently to cover the conducting tube.

The following appear to me to be advantages gained by this instrument:—

1. That no atmospheric air can gain admission during the operation; and by making a valvular opening, and careful pressure as the trochar is withdrawn, no air ought to be admitted after its withdrawal.
2. The syphon action would, I imagine, assist in keeping up a continuous flow of fluid, so long as the wall of the chest contracts, or the compressed lung re-expands.
3. The power of stopping and re-admitting the fluid at any moment through the conducting tube, by a simple movement of the piston.
4. That if the tube should get blocked by lymph, or anything should arise during the operation to make such a course desirable, the instrument may be converted into a common open canula, by unscrewing the cap and removing the piston.

This instrument may be conveniently applied to other purposes for which the common trochar is now used, as in tapping hydrocele, hydrocephalus, large chronic abscesses, etc. For paracentesis abdominis it is made of larger size, with an elastic tube three feet long. Here it presents great advantage over the ordinary trochar, by conveying away the fluid into the receiving vessel without any splashing, unseen and unheard by the patient; and by giving the power of so easily checking the flow by the piston, when required either on account of faintness or for the purpose of changing the vessel.

The instrument has been accurately made for me by Mr. Ferguson, of Giltapur-street, and it is very portable, and not expensive.

I have not yet had an opportunity of testing its efficacy on a living thorax, and should be much obliged to any Surgeon who will try it, and let me know how it works.

Westerham.

## GENERAL CORRESPONDENCE.

### COLONIAL MEDICAL PRACTICE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Having been, like M.R.C.S.E., desirous of finding a better opening for successful practice than I could meet with at home, I seized the opportunity of obtaining an appointment to an emigrant ship, to proceed to Canada and see for myself. The information thus obtained is at your correspondent's service.

Medical men, qualified in England, may practise in all colonies under British rule without further examination. The chance of making a successful practice is not great in any

part of Canada; a large proportion of the annual income must be received in the shape of agricultural produce in many parts, of which the practitioner must dispose as he best can. The larger towns are already well supplied, and the interior of the country, being deficient in that large middle class which constitutes in all long-settled countries the chief support of the Medical practitioner, offers very little inducement to any one wishing to improve his position, the risk being great and success limited. This, at least, was the conclusion to which I arrived during a stay of only two months in the country, in which time I had repeated conversations with many long resident in the colony, whose means of information were very extensive, and whose opinions coincided with that which I have expressed.

I will also state that, having since made a voyage to Australia with a like object, I found the Profession there worse off than in Canada; meeting several fellow-students (who, after having obtained their diplomas, had hastened to the "land of gold" to realise a fortune), and hearing of many more, who had not even the means of returning to their native land, but were driven to the most wretched shifts to obtain a mere sustenance.

I am satisfied that the opening in England for well-qualified men is as good as that offered by any new country, for, although we may hear of instances of remarkable success in the colonies occasionally, none but those who have seen for themselves would believe in the number who, equally talented—equally competent to the fulfilment of their Professional duties with their more successful competitors—fall through no fault of their own to make that position to which by birth and education they are entitled, and, overwhelmed in the unequal struggle with the resistless waves of adversity, "die, and leave no sign." The friends of such as these are mute, or our colonies would not long be considered "El Dorado."

Apologising for saying more than I at first intended through the importance of the subject, I inclose my card, and remain

Yours &c.

M.D.

### A FICTITIOUS DIPLOMA.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have been requested by the University of St. Andrews to beg that the following discreditable proceedings of a person falsely claiming to be a Graduate of ours may be made public through your pages.

Our Secretary recently received the following letter from one of the most eminent shipping houses connected with emigration to Australia:—

"Sir,—A Mr. T. O'Grady, now residing at New Market on Fergus, Ireland, represents that he got a diploma as M.D. from your University in 1843. He has applied to us to go in the capacity of Surgeon in one of the packets of this line to Australia, but on presenting his diploma to the Government Medical officer, it was discovered that in the body of the document an erasure had been made, and the name 'Thomas O'Grady' inserted, it is believed by the gentleman who says he is the person to whom the diploma was originally issued. Till this point is cleared Mr. O'Grady cannot pass the Government officer, and we should feel greatly obliged if you will say whether in the month of March or May 1843, a person of this name got a diploma, either as M.D. or as Surgeon, from the University of St. Andrews. We think it only fair to Mr. O'Grady to explain that he says that the name as originally written in the diploma was obliterated by accident, and therefore he put it in, so that the document might be perfect.

"We are, Sir,

"Yours obediently,

"&c.

"&c."

On the receipt of this letter, our Secretary examined the Minutes of the University, and found that no person named Thomas O'Grady had graduated at this University since the year 1800. A Mr. O'Grady presented himself for examination in the course of the year 1844, but was rejected. Such being the case, there can be little doubt that Mr. Thomas O'Grady has succeeded in obtaining the diploma of some person who graduated in the year 1843, and after an erasure in the name, his own has been inserted in its place.

It is gratifying to find that the zeal and energy of the Government Medical officer have at all events, in this instance, succeeded in leading to the exposure of a gross attempt at fraud.

I am, &c.

GEORGE DAY.

St. Andrews, March 22, 1858.

### GLONIN, OR THE NITRATE OF OXIDE OF GLYCYL.

[To the Editor of the Medical Times and Gazette.]

SIR,—A few remarks on the action of the nitrate of oxide of glycyll may prove acceptable to those who read with interest Mr. Field's letter in the *Medical Times* of last week.

Not long ago I was induced by a homœopathic friend to take an experimental dose of the first dilution of glonoin. I took less than one drop, and resolutely withstood its effects as long as I could. Before long, however, I was compelled to own to a tensive headache over the eyes and nose, extending also behind the ears, and soon followed by a tight and choaky feel about the throat like strangulation. Neither loss of consciousness nor nausea were experienced, and a walk by the side of the sea soon did away with all unpleasant feeling.

My friend was urgent with me to try a second dose. This I did not do, feeling convinced of the power of glonoin as a toxic or poisonous agent.

Of glonoin as a therapeutic agent I as yet know nothing. Pliny has said,—

"Ubi virus ibi virtus."

A *virus* there certainly is in glonoin, and the experiments of Mr. Field go strongly to prove that this body has also a *virtus* for curing a certain class of diseases.

I am, &c. JOHN C. THOROWGOOD, M.D. Lond.

Totteridge, Herts, March 20, 1858.

### PIROGOFF'S AMPUTATION AT THE ANKLE-JOINT.

[To the Editor of the Medical Times and Gazette.]

SIR,—The able lecture delivered by Mr. Spencer Wells on Pirogoff's operation, and published in your number of March 20th, is well worthy of the consideration of the Profession.

With the mode of performing the operation, and the care taken to insure the division of the plantar arteries, and not the posterior tibial artery, I quite agree, since the life of the posterior flap depends upon it.

It appears to me that the probable success of the operation is dependent upon the cause necessitating its performance.

I presume that in civil practice, at least, the ordinary cause for the operation is caries of the tarsus or ankle-joint; and knowing how liable this disease is to recur after removal, should expect its return in the remaining portion of the os calcis, and with that view should select Syme's in preference to Pirogoff's operation.

There is one point to be borne in mind in the performance of all amputations of the lower extremity, "to remove as small a portion as possible of the human frame," in which particular Pirogoff's has the advantage over Syme's. Since, however, arguing upon probabilities is little worth, let this operation have a fair trial, and then take its place in the scale of surgical operations.

I am, &c. C. F. MAUNDER, F.R.C.S.

Demonstrator of Anatomy in Guy's Hospital.

### MOVEABLE KIDNEY.

[To the Editor of the Medical Times and Gazette.]

SIR,—Should you think the following case of "Moveable Kidney" worth insertion, as an addition to those reported in a late number of your Journal, you will perhaps give it a place.

Mrs. C., aged 24 years, married six years, but has had no children, and who has for some years been suffering more or

less from severe pain in the loins, and frequent distressing neuralgia of the face, and of general feeble habit of body, requested my advice, a few days ago, respecting a "swelling," which she first noticed a fortnight or three weeks since, when, being suddenly frightened, she felt a pain in the right side, and upon instinctively patting her hand there, detected an enlargement. Suspecting it had something to do with pregnancy, she wished me to examine her. I found nothing noticeable so long as she lay supine; but upon her turning on the left side, a distinctly circumscribed tumour was readily felt towards the right side of the umbilicus. It could be pretty well grasped in the hand, and was easily pressed backwards into the right lumbar region, where the other hand then detected it, producing, upon slipping into its position, a peculiar sickening sensation to the patient; and, as she is thin, the whole movement of the kidney can be clearly traced.

Another patient, complaining of precisely the same symptoms, and not yet submitted to examination, will, I doubt not, be found in the same condition as the preceding.

Probably such cases are more frequent than at present supposed, and their detection will doubtless explain many at present anomalous symptoms, which may most probably arise when the kidney is much less moveable than those reported in the *Medical Times and Gazette*.

I am, &c. HENRY CARNLEY, M.B. Lond.

Hull, March 10, 1858.

## REPORTS OF SOCIETIES.

### THE PATHOLOGICAL SOCIETY,

TUESDAY, MARCH 16.

DR. WATSON, President, in the Chair.

#### Dr. O'CONNOR exhibited specimens of CANCEROUS DISEASE OF THE HEART AND LUNG.

A woman, aged 34, had been admitted with pericarditis and pleuro-pneumonia in association with acute rheumatism. At the autopsy deposits of cancer were found on the pleural surfaces of the ribs and on the pericardium. The left lung was extensively disorganized by cancerous disease. In the left kidney was also a malignant growth. Acute pericarditis had existed, and the heart was covered with villous lymph.

Dr. BRISTOWE inquired on what grounds Dr. O'CONNOR believed the deposits on the pericardium were cancer; he thought they looked like inflammatory exudation.

Dr. O'CONNOR replied, that Dr. Brinton had examined the specimen, and felt no doubt as to its nature.

Dr. O'CONNOR next showed a specimen of

#### FIBRO-PLASTIC TUMOUR OF THE OVARY.

It had been removed from the same patient as the previous one. The tumour was as large as an infant's head, and had occupied the space between the bladder and rectum.

Mr. ADAMS showed a specimen of

#### SPINA BIFIDA, RUPTURED BEFORE BIRTH.

The tumour had ruptured previous to birth. When the child was born the tumour was ulcerated and sloughy. The child lived four days. The nerves were found attached to the membranes of the sac. The deficiency of vertebral lamina was in the lumbo-sacral region. The child had double club-foot. Mr. Adams mentioned a second case, in the practice of the same accoucheur, in which a spina bifida had ruptured during the act of birth. In the latter the infant lived nineteen days.

Dr. GRAILY HEWITT next brought before the Society a specimen illustrating

#### FALSE CORPORA LUTEA.

The woman from whom the ovaries had been removed was single, and was believed to have never conceived. The object of exhibiting the specimens was to prove that, contrary to the generally received opinion, false corpora might have distinct lining membranes. The bodies in this instance had distinct

cavities. He had not found any liminary membrane around them.

Mr. HENRY showed a specimen of

# RECURRENT FIBRO-PLASTIC TUMOUR OF THE HUMERUS.

A woman had submitted to amputation at the shoulder-joint for a tumour in the head of the humerus, which was of characteristically myeloid structure. It was supposed that no recurrence would take place. Within eleven weeks, however, there were indications of a recurrent growth beneath the cicatrix of the operation. She died with all the symptoms of malignant disease. At the autopsy the growth on the scapula was of the size of a foetal head. There were deposits in the lungs which, like the original and recurrent growths, were of myeloid structure. (Drawings by Mr. Sibley, of the large poly-nucleated cells from the deposits in the lungs were shown, fully proving this point.) Mr. Henry pointed out the importance of this case (which was, he observed, almost a parallel to one brought before the Society by Mr. Hutchinson at a former session), as proving that myeloid tumours were not always innocent. He thought that Mr. Paget and Mr. Gray had much exaggerated the importance of the the myeloid cell formation, as a feature characteristic of a peculiar class of tumours.

A discussion followed, in which Dr. Wilks, Dr. Markham, Mr. Adams, Mr. Hulke, Mr. Nunn, and Mr. Hutchinson took part. It was generally admitted that the mere fact of myeloid cells being found in the interior of a tumour developed within bone, could not be held to indicate that the tumour would prove innocent. Dr. Wilks and Mr. Hutchinson, however, held strongly that it was possible to discriminate between the innocent myeloids and those which were really, like the specimen before the Society, examples of fibro-plastic with certain portions of myeloid structure added. Those not liable to recur were usually almost wholly made up of characteristic myeloid cells, whilst the others were fibro-plastic in the greater portions of their bulk, and only showed the poly-nucleated bodies in the interior of the bone. Mr. Hulke thought that he had seen the cartilage cells undergoing transformation into myeloid ones, but the correctness of this observation Mr. Adams seemed inclined to doubt.

Mr. SPENCER WELLS then exhibited a

## MULTILOCULAR OVARIAN CYST,

which he had removed successfully on the 19th of February. The patient was now convalescent. The cyst and contents weighed twenty-six pounds. The contents were of the ordinary viscid albuminous fluid, containing many granular cells. After emptying the large cyst and all the smaller ones by puncture, the cyst was soaked in water for some days to remove the blood, and afterwards in turpentine, until the fat was dissolved out. It was then stuffed with horse-hair and dried. When dry the hair was removed and the cyst varnished. It showed very clearly the formation of a number of secondary cysts from the wall of the primary cyst, and of still smaller cysts within the secondary formations. The patient was twenty-nine years of age, single. She was a general servant and in good health up to the age of twenty-one. She then began to complain of severe pain in the left side, low down, extending to the loins, but did not observe any tumour until three years and a half ago. The tumour increased gradually, and she was admitted into Guy's Hospital under Dr. Lever, two years ago, and tapped. After six months, she was readmitted and tapped again, and a third time after an interval of thirteen weeks. In June last she went to Lambeth Workhouse, and was tapped there four times by Mr. Bullen, at intervals of about two months, the fluid discharged each time averaging about two gallons. Undiluted tincture of iodine was injected twice, without the slightest benefit, on the contrary, the cyst appeared to refill faster than usual. She was admitted into the Samaritan Hospital on the 9th of February, and looking to her age, her moderately good constitution, her earnest desire to be relieved of a disease which made her life miserable, and the fact that her health was gradually giving way under the repeated accumulation and discharge of two gallons of albuminous fluid, Mr. Wells decided after consultation with his colleagues to extirpate the tumour. He first made an exploratory incision in the linea alba down to the cyst, emptied the principal sac, and then, after enlarging the incision to the

length of seven inches, broke down with the hand very firm and extensive adhesions to the abdominal parietes and a slighter adhesion to the omentum. The peduncle was on the left side, and so broad that it had to be tied with whipcord in three portions. Mr. Wells was prepared to use the écraseur, but was afraid to trust to it in so broad a peduncle. The peduncle was so short that it could not be fastened in the wound. The ligature was accordingly left in the abdominal cavity and fastened carefully externally by plaster. The wound was brought together accurately by deep and superficial sutures. The patient was under the influence of chloroform for forty minutes. She suffered from nausea and vomiting during the two following days, due, it appeared, rather to the chloroform than the operation, but she had no sign of peritonitis. She was kept from the first under the influence of opium, and wine was given freely. There was a very copious fetid discharge. The bowels were not opened until the tenth day, when they moved spontaneously. The ligature came away on the twelfth day with a large slough attached to it. The wound united by the first intention, except for about half an inch at the spot where the ligature had passed. There was still some discharge, but the patient eats and sleeps well, is cheerful, and beginning to walk about the ward. Mr. Wells added that this case has modified his opinion as to one source of danger after ovariectomy. He had been led by observation to believe that the presence of the sloughing stump of peduncle in the peritoneal cavity, and the absorption of fetid pus, was a chief cause of failure, and proposed to use the écraseur to avoid this danger. But he believed that in this case the presence of the ligature had been beneficial by keeping a portion of the wound open, and thus allowing a free discharge from the abdomen. For on two or three occasions, when the wound became plugged accidentally, the patient complained of a good deal of pain, and became feverish, immediate relief being afforded by a free discharge of fluid, after clearing the ligatures.

Dr. PRIESTLEY regarded the preparation exhibited by Mr. Wells as most interesting in a pathological point of view. The usual received theory of the development and structure of multilocular ovarian cysts—and this theory seemed rather to gain ground than otherwise—was, that a single cyst was first formed, and secondary and tertiary cysts were developed in its interior by an endogenous mode of growth. Dr. Priestley had, however, previously been led to believe that this explanation would not apply to all ovarian cysts—perhaps applied only to exceptional cases. In the specimen before the Society it was evident that most of the cysts were developed quite independently of the principal cavity, and independently of each other, the mass of smaller ones being attached to the lower end of the tumour, which took the form of the pelvic cavity; while the cysts here grew outwards or into each other, just as they encountered least resistance. It was true that scattered small ones were found here and there in the largest cavity; but these were developed in the substance of the fibrous wall, had at first a flattened form, and were covered by the serous membrane lining the largest cyst. They might possibly have had their origin in a portion of ovarian stroma carried upwards in the growth of the cyst. The deduction he considered to be a practical one; for, however valuable the treatment by injection might be in simple cysts, one could scarcely hope to check such growths as that present by injecting iodine or other irritants into the largest cyst, the smaller being separated by such strong fibrous partitions from it. Had the smaller depended on the largest cyst for their growth and nutrition, one might be sanguine that, in arresting the growth of the one, the other would be similarly affected.

Dr. QUAIN showed specimens of

## DISEASED SUPRA-RENAL CAPSULES WITH BRONZED SKIN.

They had been sent to him for exhibition by Dr. Bucknill, under whose care the patient had been, as a lunatic, in the Devon County Asylum. When admitted in May 1857, the subject of the case, a woman aged 47, showed no peculiarity of colour excepting a slight sallowness. She had delusions, and was much excited. A month after admission it was noticed that her face and hands had become very dark. The brown tinge afterwards spread over the surface generally, and she became emaciated and very feeble. On July 11 she had an apoplectic seizure, and on September 20 a second. In January 1858,

her skin was described as being as dark as that of a mulatto, having however a decided yellow tinge. On February 24 she died, in consequence of a third attack of apoplexy. At the autopsy it was noted that the skin had become much lighter than during life, being in places almost of natural hue. One supra-renal capsule appeared healthy, or nearly so, whilst the other was destroyed by a form of atheromatous degeneration.

Mr. HOLMES next showed specimens of

#### DISEASED SUPRA-RENAL CAPSULES.

The organs had been removed from the body of a young man who had died of phthisis in St. George's Hospital, and were both of them extensively infiltrated by tubercle, though not wholly destroyed. During life, no darkened state of the skin had been noticed; but when, after the attention had been directed to it by the discovery of diseased capsules, a careful inspection of it was made, there were seen to be numerous small scattered dark spots. Some of these were about the size of a fourpenny-piece. Mr. Holmes was, however, inclined not to attach any importance to them, as he believed the stain was epidermal only, and did not involve the true skin.

These specimens, as well as the preceding, were referred to the Standing Committee of the Society on this subject for report.

Dr. MARKHAM exhibited

#### THE REMAINS OF A PLEURAL ABSCESS.

The specimen was a rare one; and of interest, because it demonstrated the fact of the spontaneous cure of abscess of the pleura. The man from whom it was taken died of disease of the heart. It consisted of a closed cartilaginous-like tube, about five inches long and one inch broad; its walls being about one-twelfth of an inch thick. When cut across it resembled very closely a flattened aorta. It contained no fluid matter. The hardish gritty particles scraped from its inner surfaces consist chiefly of cholesterine and granular matter. This contracted tube was firmly attached to and imbedded in the pleura, being fixed down along the outer side of the left lung; firm thickened bands of the pleura radiated from its borders over the lung, indicating the fact of its contraction. The lung itself had recovered from the compression, to which it must have been once subjected by the abscess. Dr. Markham concluded, from its position, that it must have been an encysted abscess.

### WESTERN MEDICAL AND SURGICAL SOCIETY.

FEBRUARY 19, 1858.

WM. MARTYN, Esq., Vice-President, in the Chair.

Dr. FINCHAM read an abstract of cases of acute inflammatory disease with especial reference to treatment.

The cases, which were in the main drawn from the author's note-books at the Westminster Hospital, consisted of acute inflammations of the lungs, pleura, and heart, chiefly of the first two, in the form of pleuro-pneumonia. The object of the paper was to show that, in the great majority of such cases, the antiphlogistic treatment, meaning by this term *general* bleedings, large doses of antimony, and the induction of mercurial action, is not necessary, but that patients will sometimes recover well and rapidly under very simple treatment, as by diaphoretics and counter-irritants, sometimes under stimulants pushed to the fullest extent, and sometimes under what is practically no treatment at all. As to pneumonia, he regarded the local inflammation as the result of a previous unnatural condition of the blood, and to deserve a place in the category of fevers. Indeed all fevers, whether eruptive or otherwise, might be considered as cases of constitutional disturbance followed by local inflammation; thus scarlatina was attended by inflammation of the throat, and typhoid fever by inflammation of the small intestines. The cardiac inflammation accompanying acute rheumatism and Bright's disease is doubtless the effect of an unnatural condition of the blood; the difference between these inflammations and those connected with fevers in the ordinary sense of the word, being

that in the latter the morbid agent is introduced from without, while in the former it is generated within. It would be irrational to suppose that such an inflammation could be cut short by large bleedings, any more than if it accompanied erysipelas. On the ground then of an identity, or at least an analogy in the pathology of acute inflammations and of fevers proper, it was urged that a treatment similar in principle should be adopted in both classes of disease.

Mr. KEEN exhibited a specimen of cardiac apoplexy. The patient died suddenly, and the heart generally was soft and flabby. The right ventricle presented in its interior a large fibrinous clot, which was quite dry, had fringed edges, and was adherent to the endocardium, and was with difficulty removed. Corresponding with this, intermixed with the carnea columnæ, was an extravasation of blood, with bands of lymph extending through it.

### PARLIAMENTARY INTELLIGENCE.

#### HOUSE OF LORDS.

MARCH 18.

#### MEDICAL REFORM.—SALE OF POISONS.

Lord TALBOT DE MALAHIDE, in rising to ask the First Lord of the Treasury what were the intentions of Her Majesty's Government with respect to Medical reform, and the regulation of the trade in poisons, said that the question of Medical reform was one of great importance and anxiety to a large class of the community. The Medical Profession were now better prepared for legislation on this subject than they had been for many years. The chief objects which this noble Profession desired were, first, the introduction of uniformity in the test of the different branches of the Medical Profession, so that those gentlemen whose studies and attainments placed them on an equal level might occupy the same favourable position; secondly, that there should be no artificial difficulty to prevent a person of talent and experience from attaining the highest *status* in his Profession; and, thirdly, that the Legislature should guard against the intrusion of incompetent men into the Profession, and protect the public against the evil of quacks and imposters. Last session two Bills on Medical reform were brought into the other House, but neither obtained the sanction of the Government. Two Bills were now in contemplation by independent members of the other House, but unless those Bills obtained the concurrence and assistance of the Government there was little chance of their passing. With respect to the sale of poisons a committee of their lordships' House sat last session and took a good deal of evidence, which established the necessity for Legislation. He was aware that a difference of opinion existed on this subject, but he thought that it deserved the attention of Her Majesty's Government.

The Earl of DERBY said that the noble lord had very properly brought under their lordships' attention two subjects of importance, to which the noble lord had, he knew, given much attention. At the same time, he must remind him that there was a certain class of cases with regard to which they were all agreed that something ought to be done, but when they came to consider the details of a measure, very few agreed upon what ought to be done. There was no stronger exemplification of the truth of this remark than was afforded by the question of Medical Reform, for the members of the Medical Profession were not altogether agreed upon what was wanted, and their disagreement rendered it almost impossible to pass any satisfactory measure. He might mention as an analogous case, that when he was a member of the House of Commons he hardly recollected one year in which some member—generally a young and enthusiastic member—did not bring in a Bill for the reform of the laws regulating the salmon fishery. (A laugh.) They were always told that there was a necessity for immediate legislation on the subject, and Parliament was induced to interfere; but as surely as a Bill was passed in one session, another had to be passed in the next to amend it. (Hear, hear.) Now he feared that this was very much the case with regard to Medical Reform. The law as it stood was certainly not creditable to the country, and therefore he thought something ought to be done. The noble lord had not, however, done justice to the efforts

which had been made in the House of Commons to amend the law. It was true that last year two Bills were introduced; but this year, so great was the excitement on the subject, that no fewer than three Bills had been brought into the other House by three different members. Amid such a conflict of opinion he was not prepared to say that the Government were ready to enter into the lists and bring forward a fourth Bill on their own responsibility; but, considering the intimate acquaintance with the subject possessed by those three gentlemen, it was the intention of his colleagues in the other House to give their best attention to the Bills which had been introduced, and to endeavour, by some amicable arrangement with the different parties, to frame such a measure as would be most generally approved, and as would meet the views of the Profession at large. As to the sale of poisons, the noble lord was aware that a Bill was introduced on that subject last year by his noble friend the late President of the Council. That Bill was sent to a committee, which suggested several amendments; and he (Lord Derby) had lately communicated with his right hon. friend the Secretary for the Home Department, calling his attention to the Bill so amended, and requesting him to communicate more especially with the Pharmaceutical Society on the subject. If it was found that there was any chance of a Bill being so framed as to receive the approbation of Parliament, it would be introduced into the other House.

#### HOUSE OF COMMONS.—MARCH 23.

##### MEDICAL REFORM.

Mr. COWPER, in moving for leave to introduce a Bill to regulate the qualifications of practitioners in medicine and surgery, said, the proper objects of all legislation upon the subject appeared to him to be, in the first place, that the qualification required by law to entitle a person to become a medical practitioner should be maintained at a certain standard, and should be valid in all parts of the united kingdom; and, secondly, that a register should be established, which would enable the public generally, and the less educated portion of the community in particular, to ascertain what practitioners were really qualified, and in what the nature and extent of their qualification consisted. Constant reference was made in our statutes to the due qualification of medical men, and public appointments could generally speaking be held only by persons who were legally qualified. That was a principle which he thought it was desirable to uphold, notwithstanding that he was disposed jealously to guard the right of private individuals to consult whomsoever they pleased, whether they happened to be learned or unlearned. For appointments connected with the army, navy, friendly societies or other institutions, it seemed right that the restriction should exist, in order that from caprice or other motives unqualified persons might not be chosen. That practice had been justified by usage from the earliest times. There were dozens of Acts of Parliament concerning the Medical Profession, always referring to qualified persons, but none settling what the qualification should be. He believed that former efforts in that direction, although defeated by the conflict of antagonistic interests, had not been without some use, and there was an extending opinion of the necessity for the organization of the Profession, for some established qualification, and for some arrangement whereby that qualification might be made known. One of the great defects of the legal qualification at present existing was that it was partial in application and jurisdiction. Surgeons had no legal definition of qualification, and Sir B. Brodie or any other Surgeon was not in law legally qualified. Then, again, an English Practitioner had no standing in Scotland or Ireland, and *vice versa*; while even the London University, which conferred degrees for practice in the country, could not authorize any one to practise in the city wherein it was situate, and whence it derived its name. It was agreed that the first step must be to establish a better *minimum* qualification, without which no one should be permitted to practise. The proposal in the Bill of last year was that a new board of examiners should be created, consisting of persons delegated by the College of Physicians, the College of Surgeons, and the Society of Apothecaries; but the Bill altogether deprived the Universities of any voice in the granting of licences or the

direction of education. The Bill which was prepared by the select committee of 1856, and which was laid upon the table by the noble lord the member for Haddingtonshire (Lord Elcho), provided a new board of examiners, consisting of persons nominated by the Medical Corporations and the Universities, the intention being that the Universities should examine as to the sciences collateral to the study of medicine, while the Professional Colleges should examine as to Medical science itself. There were, however, objections that that plan would compel graduates to undergo a second examination after obtaining their degrees, and there would be also a difficulty as to the apportionment of the fees among the various bodies entitled to receive them. He thought it would be wise not to make any change that was not absolutely necessary, and the best course would be to leave the examination to the present licensing body, under the general control and supervision of a general council, to whom power should be given to decide upon what examination should be required, or what certificates should be produced before any person could be placed upon the register. If the Council had the right to be present at the examinations of the College of Surgeons and the Society of Apothecaries, they would be enabled to prescribe the standard which should be required, that at present existing being admitted to be too low. The consequence of the low standard of examination at present was, that the Profession was overrun with young men, who were barely able to exist. With regard to the register, great difficulties had been raised. The Bill which was introduced last year by the hon. member for Newcastle (Mr. Headlam) proposed a new definition of the Medical Profession—the higher class to be called Physicians and the lower class Surgeons. That created a difficulty, as many who were always considered Surgeons would then be called Physicians, while the ordinary understanding was, that a Physician attended to the interior of the human body, while a Surgeon attended to the exterior. The College of Physicians had always been anxious that they should be distinguished by being placed upon a separate register. There would be no difficulty in meeting their wishes; but it was a minute point, and might well be left to the consideration of the Medical Council. He now came to the mode of constituting the Council. Since 1834 the proposals had oscillated between a Council nominated by the Crown and a Representative Council. In 1848 the Medical Profession were unanimous in favour of a nominated Council. As they subsequently declared in favour of a Representative Council, however, he recommended the House to adopt that plan, which would be open probably to less objection than a Council nominated by the Crown. He proposed that it should consist of six members to be nominated by each of the present licensing bodies, and six to be nominated by the Crown. In order to connect the Council in some way with the Executive, it had been suggested that the President should be either the Secretary of State for the Home Department or the President of the Board of Health; but he thought that a better course would be to follow the precedent of many other Commissions, and to provide that the rules of the Medical Council should only be adopted when they had been confirmed by an Order in Council. By these means the Medical Profession would derive the benefit of an organization which it had never had before. While the legal, the military, and the naval professions were amply represented in that and the other House of Parliament, it was rarely that one of the Medical Profession ever found his way there; and yet there were sanitary and other social questions with which no men could be more competent to deal. (Hear, hear.) Moreover, the Medical Profession required the exercise of as great skill and was actuated by as noble an aim as any other profession, for it was not less noble to seek to save than to destroy life, or to preserve life than to preserve property. In conclusion, he moved for leave to bring in a Bill to regulate the qualification of practitioners in medicine and surgery. (Hear, hear.)

Mr. WALFORD said that the Bill which the right honourable member had suggested appeared to be by far the best proposition which he had yet heard on the subject, and he should not object, therefore, to its introduction.

Lord ELCHO said that the Bill which had just been proposed by his right honourable friend was an old friend with a new face, for it was precisely the same measure which he had himself ventured to introduce in 1856; and wonderful as were

the changes which daily took place around them, there was no change more wonderful, perhaps, than that which had occurred in the mind of his right hon. friend upon this subject. After relating the history of the rival Medical Bills which had been introduced by the hon. member for Newcastle and by himself, the noble lord observed, that he should be very happy to modify that part of his own Bill which related to the institution of the Council in the direction of the Bill of the right hon. gentleman.

Mr. HATCHELL approved the Bill, and thought it met the difficulty of the constitution of the Council in a satisfactory manner.

Leave was then given to bring in the Bill, which was read a first time.

## MEDICAL NEWS.

**APOTHECARIES' HALL.**—Names of Gentlemen who passed their Examination in the Science and Practice of Medicine, and received Certificates to Practise, on Thursday, March 11, 1858:—

JONES, DAVID KENT, Beaumaris.

LYNES, EDWARD, Coventry.

ROBERTS, CHARLES.

ROGERS, ROBERT JAMES, Brighton.

THOMAS, EDWARD WYNN, Oswestry.

WYNTER, HUGH BOLD, Kensington.

Also on the 18th March:—

ALFORD, HENRY JAMES, Taunton.

MORRIS, RICHARD, Aberystwyth.

PEARSON, JOHN TAYLOR, Wellington-road, Stockport.

SAINTER, JAMES DOW, Manchester.

SARGANT, WILLIAM THOMAS, Bletchingley.

## DEATHS.

**CURLING.**—On the 12th inst., at Shepherd's Bush, Thomas Curling, formerly of Steyning, Essex.

**HAMMOND.**—On the 14th inst., William Hammond, of Handsworth, Staffordshire, aged 50.

**MORRIS.**—At Delhi, on the 13th Jan., William Gardiner Morris, M.D., aged 32.

**PICKES.**—On the 12th inst., Henry Beresford Pickess, M.R.C.S. Eng. and L.S.A. 1844, of Aylesbury, aged 35.

**VIGURS.**—At Falmouth, John Vigurs, M.R.C.S. 1806, aged 77.

**VINCENT.**—At Camborne, Philip Vincent, aged 68.

**WALKER.**—On the 9th inst., at Orchard-House, Teignmouth, Edward Dering Walker, M.D.

## APPOINTMENTS.

**DR. R. S. DAVIS** has been elected Physician to the Worcester Infirmary, in the place of Dr. Malden resigned.

**THE Queen** has been pleased to appoint Claudius Francis Du Pasquier, Esq., to be Apothecary in Ordinary to her Majesty's Household (jointly with John Nussey, Esq.), in the room of Charles Craddock, Esq., deceased.

**CITY OF LONDON TRUSS SOCIETY.**—Mr. J. Abernethy Kingdon has been unanimously elected Surgeon to this Institution.

**MEDICAL REFORM.**—At the election at present pending for a member to represent the University of Dublin in Parliament, in the room of the Right Hon. Joseph Napier, recently appointed to the high and important office of Lord Chancellor of Ireland, Dr. Gayer, one of the candidates, in his address on the hustings, expressed his intention, if he should be returned, of devoting his attention to the subject of Medical Reform, and of supporting those changes which are advocated by the most distinguished members of the Medical Profession in Dublin.

**KENT COUNTY OPHTHALMIC HOSPITAL.**—The eleventh annual report of the Board of Management for the year 1857

shows that 2946 patients have been under treatment during the past year, and that of these, 249 have been admitted as in-patients, whilst the separate visits of the out-patients to the Hospital during the year amounted to 13,867. During this one year the operations performed for cataract numbered 65, and the entire number of operations performed upon the eye was 258. The Board report the resignation of Mr. Charles O'Callaghan, as Assistant-Surgeon to the Hospital, and the appointment of Mr. Sydney Proctor, as Resident Medical officer, at a salary of £100 per annum, in the place of Mr. Lewis, who filled the office of Dispenser.

**LATENT LIGHT.**—M. Niepce de St. Victor is confirming his views that light is capable of being absorbed and retained, for a season, in the absorbent body. He takes a piece of plain paper which has been kept for some days in the dark; and, placing upon it a negative photograph, he exposes it to sunshine. After it has been exposed for a period, regulated by the intensity of the light, the paper is again removed into obscurity, and then washed over with a solution of the nitrate of silver. In a little time an image will develop itself upon the paper, which can be fixed by merely washing in water. Here we have the nitrate of silver undergoing decomposition by the light absorbed by the paper during its brief exposure to sunshine. The *Athenaeum* says, "The power of 'emmagasinement' is possessed in different degrees by dissimilar bodies, one of the most remarkable being the nitrate of uranium. Indeed, the bodies distinguished by Prof. Stokes as fluorescent bodies appear to possess this power in an eminent degree."

**DIPHTHERITIS IN CALIFORNIA.**—We extract the following passage from a private letter just received from an English Physician practising at Sacramento in California:—"I see by the papers that diphtheritis has been making considerable ravages lately in England. We have had a great deal of it here during the last four years. I have seen it both in the plains, and as bad as anywhere at an elevation of 4000 feet, but then it only occurred when the locality was relatively low, the places being surrounded by higher hills. The same was the case in an epidemic of dysentery which I witnessed in the mountains, not a single bad case occurred among the population residing on the ridges. The diphtheritis requires here a stimulant treatment, chlorate of potash, brandy, and eggs, etc., and I make the patients swallow a good deal of charcoal to neutralise the secretion that finds its way into the stomach from the pharynx. Here the disease is undoubtedly infectious; there has been but little in the city, but around in the country it has been very fatal. I believe, however, the great mortality is from the treatment. There is a place some twenty miles from here, called Cache Creek, where the disease is almost endemic, and every outbreak, at least in the spring, summer, and autumn, takes place after a N.W. wind, which is with us a hot wind."

**ADDRESSES FROM THE COLLEGES OF PHYSICIANS AND SURGEONS TO THE LORD-LIBUTENANT OF IRELAND.**—On Thursday, the 18th inst., a deputation from the Royal College of Surgeons of Ireland attended at the Castle to address the Earl of Eglinton on his return to Dublin as Lord-Lieutenant of Ireland. In the course of his reply his Excellency observed, "I am well aware that there is no class to which the community is more deeply indebted than the men of your profession, and the skill with which you alleviate the sufferings, and the zeal and liberality with which you devote yourselves to the service of your fellow-creatures, is a subject too large and too sacred for me to more than allude to on an occasion such as this. It will at all times give me pleasure to attend to the interests of your institution and witness its efficiency; and I have no doubt that the high character it has borne will not be impaired under your auspices." The address from the College of Physicians was presented on Monday, the 22nd inst., and was read by the President, Sir Henry Marsh, Bart. The College stated that "Incorporated for the regulation of the profession of medicine in this part of the United Kingdom, we consider it our duty upon several occasions respectfully to invite the attention of her Majesty's Government to the state of the law for the preservation of the public health; and recently, at the request of the noble Earl, your Excellency's predecessor, we offered some suggestions relative to its amendment, regarding the sale of poisonous substances, certain of which were subsequently embodied in a bill introduced into Parliament—a measure which, we observed with regret, it was

not intended should apply to Ireland. To this important subject we trust your Excellency's attention may ere long be directed. We desire to tender to your Excellency our assistance in the promotion of every measure devised for the preservation of the public health; and, in conclusion, we trust that your Excellency will afford to us your countenance and support in our efforts to uphold the position, protect the interests, and extend the usefulness of the Profession we represent." In the course of his reply, his Excellency said:—"I shall be at all times ready to listen and advise with you upon any suggestion which may occur to you for the preservation of the public health, and for promoting the efficiency of the Profession to which you belong, and I shall endeavour to secure for this country a participation in any useful measure that may be brought before Parliament."

**MERCER v. IRVING.**—(Before Mr. Justice Williams and a Common Jury.)—This was an action to recover the penalty for the alleged infringement of one of the covenants of a bond entered into by the defendant.—Mr. Bovill, Q.C., and Mr. Creasy were for the plaintiff; and Sergeant Ballantine and Mr. Prentice for the defendant.—The parties to this action are both in the Medical Profession, and it appeared that the latter had been in practice at Wadhurst, in this county, but had sold his business to the plaintiff for £150, and he at the same time executed a deed whereby he engaged to forfeit double the amount of the consideration money if he practised within a mile of Wadhurst church after he had disposed of his business.—The case on the part of the plaintiff was that the defendant had prescribed for certain patients residing within the specified distance, and a surveyor was called who proved that the distance, "as the crow flies," of the residence of one of the patients, was 1600 odd yards, another 1500, and the whole just under a mile; but it was admitted that in one or two cases the distance from Wadhurst church to the house of the party by the road exceeded a mile. The cause was heard at the last summer assizes, when the plaintiff was non-suited in consequence of not being able to prove the exact distances.—Mr. Justice Williams ruled in the course of the case upon the form of the bond, that the plaintiff could not recover the whole amount of the penalty, and that it was merely a question of damages.—Sergeant Ballantine addressed the jury for the defendant, and said he did not deny that he might have attended a few patients just within the prescribed distance; but he had no intention to break the agreement he had entered into, and it was merely an accident, and he urged that the very smallest amount of damages would amply satisfy the justice of the case.—The jury, after a short deliberation, returned a verdict for the plaintiff—damages, £25.

**ADVERTISING DENTISTS.**—**BLOOMSBURY COUNTY COURT.**—*Webster against Mallam, calling himself "Cartwright and Davis."*—In our Number of 6th February we gave a short report of an application to the police magistrate for a warrant against this defendant for obtaining money from the plaintiff in a fraudulent manner. The magistrate refused to grant such summary remedy, and the question in issue was tried in this Court last week. Mr. Bowen May, solicitor, represented the plaintiff, and Mr. James, the barrister, appeared for defendant. Mr. May stated that the action was brought to recover the nominal sum of £10; but his client brought the matter forward to expose a gross fraud that was constantly practised on the public. Mallam was in the habit of advertising as a dentist, using the eminent name of Cartwright. His client believing that the "firm" in Somerset-street were connected with the celebrated dentist, employed defendant to make her an "upper" and part of an "under" for £10, upon the distinct understanding that it was to be set in gold, and to be a perfect fit; but when the money was paid the plaintiff found that she had been grossly imposed on, and that the metal was spurious and worthless. A gentleman happening to hear of the fraud, sent the plaintiff to his dentist, and also to his solicitor, upon which he applied to a police magistrate for a warrant against Mallam; but as his Worship said the only mode was to give the defendant into custody for the fraud, or to sue him in the County Court, the plaintiff appeared on the present occasion. The plaintiff confirmed the opening of her solicitor, and stated that the set made by the defendant was useless, and could not be worn; but that made by Mr. Hasler Harris was perfect, and with it she could masticate. Mr. Hasler Harris proved that he was

assistant to Mr. Robinson, of Gower-street, and had submitted the defendant's metal to chemical tests, and that it was nothing but dental alloy (a combination of silver, platinum, and a small portion of gold), the total value of which, with the teeth, would not exceed 30s.; that he had fitted in the defendant's "piece" to plaintiff's mouth, and in some places there was room for a crown-piece between the plate and the mouth. Mr. Samuel Cartwright, of Old Burlington-street, confirmed Mr. Hasler Harris, examined the plaintiff's mouth, and pronounced the piece she then had in as very well executed, and said that the defendant's work was worthless, except as regarded the trifling value of the materials. Mr. Tomes, of Cavendish-square, agreed with Mr. Cartwright and Mr. Hasler Harris as to the teeth being quite useless to the plaintiff, and that a brazier with a little practice was able to make a piece like that produced. He added that the Society of Dentists, to which he belonged, had established a rule that no dentist should advertise. The defendant and two other witnesses were called on the other side; but his Honour gave judgment for the plaintiff for the debt claimed, and costs.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, March 27, 1858.

### BIRTHS.

Births of Boys, 1026; Girls, 934; Total, 1960.  
Average of 10 corresponding weeks, 1848-57, 1639.

### TO CORRESPONDENTS.

*J.C.*—No reports of the Medical Society of London appear in the Medical Times and Gazette, simply because the secretaries do not send any reports of the proceedings of the Society.

*W. S. S.*—1. No new edition of the London Pharmacopoeia is expected at present. 2. Celsus and Gregory only. 3. Yes.

*Fair Play.*—The subject shall be commented on next week.

*Chemist.*—Murexide, a splendid crimson colour, is obtained from guano. "Prout long ago found purpurate of ammonia in the feces of serpents."

*Philogardenopolis.*—The bulb of the *iris juncea* is far more nutritious than the potatoe. It is now cultivated in France, having been introduced from Algiers.

**Anti-Ambig, junior.**—It would not be fair to publish the reply to Mr. Field anonymously. We shall be glad to insert the letter next week, with the name of the writer.

**Butcher's Saw.**—We received a long letter from Mr. Butcher last week—which was unfortunately mislaid. The facts of the case appear to be that Mr. Butcher is fully entitled to the credit of making the saw known to the Profession; and that he was quite unaware of the fact that a similar instrument had been given in 1832 to Dr. Laurie by Dr. Graham.

**A Subscriber.**—1. Are Acting Assistant-Surgeons of the Turkish Contingent entitled to the Order of the Medjidie?—Not unless recommended for distinguished service. 2. What qualifications or examination is required for Surgeons in the Peninsular and Oriental Steam Navigation Company's service?—A British qualification, and examination at the Navy Medical Department.

**Mr. Syme.**—The North Briton, of March 20th, contains the following curious correspondence said to have taken place between Syme and Liston on the allegation that Mr. Syme had purchased the chair of Clinical Surgery of Professor Russell, by "paying him £300 a year so long as he lived":—"Dear Liston,—Do you, like some others, believe that I bought the chair of clinical surgery?" to which Liston answered—"Dear Syme,—If you didn't buy it, how did you get it?"

**Dr. Graily Hewitt's** remarks at the Harveian Society upon Mr. Lobb's paper were to the effect that "In applying galvanism for the cure of cases of paralysis, it was necessary so to apply the conductors, as directed by Duchenne, that the muscles and not the skin alone might be affected by the current."

**ERRATA.**—In our last number, at page 289, 2nd column, 17 lines from bottom, for "altered portion" read "altered position."—In our notice of the annual meeting of the Association of General Medical Practitioners of Ireland in our last number, Dr. Nalty's name was, by mistake, printed Nalby.

**"Does Mr. Churchill allow this?"**—The advertisement has been received, and referred to Mr. Churchill, who informs us that he infers every gentleman legally qualified follows his profession honourably unless the contrary is proved. On reading the quackish advertisement, Mr. Churchill returned all copies of the work to the author, and demanded that his name should be withdrawn from future advertisements.

## GLYCYL.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I read with much interest, in your paper of last Saturday, Mr. Field's account of the therapeutic effects of the Nitrate of the Oxide of Glycyl, but was sorry he said so little of its chemistry and mode of preparation. Perhaps some of your numerous correspondents would favour me and other readers with some more explicit information on this subject in your next. I am, &c. ABERDONIENSIS.

Aberdeen, March 23, 1858.

## THE MUSEUM ASSISTANT AT THE COLLEGE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In compliance with my previous communication, I beg to inform you that in answer to my letter to the Council of the Royal College of Surgeons, which embodied the same facts as my letter to yourself, I have received a short note from the Secretary, simply stating that the letter had been laid before the Council; in other words, a tacit acknowledgment from them of the truth of the statements it contained.

Perhaps this example of mine may prevent others from indulging in the same pleasing delusion that I did,—viz. that something else besides interest or caprice might assist me when an appointment was to be made at the Royal College of Surgeons of England.

Thanking you much for inserting my former letter,  
I am, &c. GEORGE W. LAWRENCE, M.B. Lond.  
Camberwell House, March 24, 1858.

## IMPACTION OF THE PULMONARY ARTERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In the last number of your Journal for March 20th, there is related Dr. George Robinson of Newcastle-on-Tyne a case of "Acute mania, with softening of the brain and sudden death, from the impaction of a fibrinous coagulum in the pulmonary artery." It is not my intention to venture upon an opinion as to the real cause of death in this particular case; but I do venture to submit, with all due deference, that the conclusion arrived at by the author, viz. "that death resulted from obstruction of the pulmonary artery," is erroneous. The patient's death took place suddenly and unexpectedly, but the appearance of the coagulum found in the artery would indicate that for its formation some time must have been required; for a fibrinous coagulum, four inches in length, and extending not only into the bifurcation of the artery, but also into a secondary division, could not have been a sudden production.

That it was not formed gradually during life is, I think, obvious from the fact of the non-occurrence of any previous symptoms of disordered circulation. The description of the appearances observed seems to me to indicate that the coagulum was formed after death; and there was amply sufficient time for this occurrence to take place, viz. fifty hours. I have seen in post-mortem examinations similar coagula, though not so large as in the case related, extending into the divisions of the pulmonary artery, in cases of death from other causes, and in which there has been no suspicion as to the presence of the coagulum having anything to do with the patient's death.

Apologising for thus trespassing on your valuable space,  
March 23, 1858. I am, &c. MEDICUS.

## PROVIDENT DISPENSARIES.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I read with great interest your article on Provident Dispensaries, but like many other intrinsically excellent institutions, they are susceptible of considerable abuse. Such an institution may be "Provident" in three senses,—provident for the patient, provident for the Medical officers, or mutually provident. The latter species of "provision" no one can object to, but, unfortunately, they generally degenerate into the second. There at present exists an institution of the kind in my parish, called the "St. Marylebone Provident Dispensary;" the patients are treated there at the average rate of two-pence per head per annum; the Medical men, on the other hand, used to receive about £250 a-year for their disinterested services, but you will perceive that the amount expended in the cure of the patients, and the amount in salaries to the Medical men, are in inverse proportions; the natural consequence has been that the "St. Marylebone Provident Dispensary" has become a nice quiet snuggery for its Medical officers (one a shop-keeper), to the great detriment of all the General Practitioners of the parish. I am, &c. VERAX.

March 18, 1858.

## CHLORODYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having, like Dr. Medlock, been operating on Chlorodyne with a view to answering questions put to me by various Medical gentlemen as to its probable composition, I beg to say that I fully agree with the statements contained in Dr. Medlock's letter as published in your last number. The quantity of chloroform is exactly equal to  $\frac{1}{4}$ th its bulk, but that of the prussic acid is but a mere dash, judging from the cyanide of silver I obtained. The following formula may be taken as an index of its composition:—

R. Burnt sugar, 1 drachm.  
Hydrochlorate of morphia, half a grain.  
Distilled water, 2 drachms.  
Oil of peppermint, 6 minims.  
Diluted prussic acid, (P.L.), 5 minims.  
Tincture of capsicum, 6 or 8 minims.  
Chloroform, 1 drachm.  
I am, &c.

Cheltenham, March 24, 1858.

JOHN HORSLEY, F.C.S.

## COMMUNICATIONS have been received from—

DR. RIGBY; DR. SYMONDS, Clifton; DR. MACKENZIE, Glasgow; MR. WHARTON JONES; MR. BUTCHER, Dublin; MR. H. SMITH; D. G. JOHNSON; MR. PRESCOTT HEWITT; DR. DAY, St. Andrew's; MR. MARTIN; DR. HALFORD; DR. WHITEHEAD, Manchester; DR. PRIESTLEY; DR. GRAILY HEWITT; DR. SUTHERLAND; MR. MACKENZIE; MR. MAUNDER; DR. MOSH; DR. TRIFE; MR. JAMES, Exeter; DR. DAVIS, Worcester; MR. HOOD; MR. JOAD; MR. EVANS; MR. SYMES; MR. M'DERMOTT; MR. ABRAHAM; DR. O'CONNOR; MR. BOWLES; ABERDONIENSIS; MR. BARLOW; MR. HORSLEY; DR. V. HUGHES; MR. GRANTHAM; MR. HENRY LEE; MR. LAURENCE; MR. WRIGHT; DR. HARLEY; DR. A. VON GRAEFE, Berlin.

## APPOINTMENTS FOR THE WEEK.

## March 27. Saturday (this day).

Operations at St. Bartholomew's,  $\frac{1}{4}$  p.m.; St. Thomas's, 1 p.m.; Westminster, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."  
MEDICAL SOCIETY OF LONDON, 8 p.m.: Dr. Stodet, "On Vomiting in Pregnancy."  
ROYAL INSTITUTION, 8 p.m.: Professor Bloxam, "On the Chemistry of the Elements which circulate in Nature."

## 29. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 8 p.m.

## 30. Tuesday.

Operations at Guy's, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."

## 31. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 8 p.m.

## April 1. Thursday.

Operations at St. George's, 1 p.m.; Middlesex,  $\frac{1}{4}$  p.m.; Central London Ophthalmic, 1 p.m.; London,  $\frac{1}{4}$  p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."  
CHEMICAL SOCIETY, 8 p.m.  
LINNEAN SOCIETY, 8 p.m.  
HARVEIAN SOCIETY: Dr. Handfield Jones, "On the Theory of Elimination in the Treatment of Disease."

## 2. Friday (Good Friday).

## EXPECTED OPERATIONS.

Westminster Hospital.—The following operations are expected on Tuesday next, at 2 o'clock:—  
Operation for prolapsus ani, Mr. Holt. Extirpation of eyeball, Mr. Holthouse.

**Horniman's Pure Tea, the leaf**  
not coloured.—Rich full-flavoured TEA of great strength is thus obtained, as importing it not covered with powdered colour prevents the Chinese passing off the low-priced brown autumn leaves as the best. The "Lancet" (Longmans, p. 318) states of Horniman's teas:—"The Green not being covered with Prussian blue, etc., is a dull olive; the Black is not intensely dark." Wholesome and good Tea is thus secured. Prices 8s. 8d., 4s., and 4s. 4d. per lb. London agents:—Parrell, 78, Cornhill; Biphinstone, 227, Regent-street; 366, Oxford-street, and 91, Throgmorton-street, Bank; Wolf, 75, St. Paul's-churchyard; Dedson, 96, Blackman-street, Borough. Sold in Packets by Horniman's Agents in all parts of the kingdom.

TO SURGEONS, APOTHECARIES, AND DRUGGISTS.

## Important Saving, by Prepayment,

in the PURCHASE of  
NEW WHITE ROUND MOULDED VIALS OF THE BEST QUALITY.  
PELLATT and Co. submit the following PRICES of VIALS, for PRE-PAYMENT only:—

1 oz., 10 dr., and 1 1/2 oz. per Gross, 6s.	In quantities of not less than
14 dr., and 3 oz. " 7s.	Six Grosses, assorted to suit the
3 oz. " 8s.	convenience of the purchaser,
4 oz. " 10s.	delivered to carriers in London.
6 oz. " 15s.	No charge for Package.
8 oz. " 18s.	Breakage at risk of Pur-
4 1/2 oz. graduated in 3 doses, " 12s. 6d.	chaser.

The above Prices being based upon a calculation which excludes all charges whatever between the Manufacturer and the Consumer, no attention can be paid to any order not accompanied by a remittance in full, made payable in London.—P. and Co. do not supply Green Glass.—Orders and remittances to be addressed,

PELLATT & Co.,  
FALCON GLASS WORKS, LONDON.

BOWLES and SONS, Label and General Printers, Lithographers and Engravers, 27, BUCKLESBURY (near the Mansion House), E. C., and 274, Whitechapel-road, London. Established nearly 80 years.

## Surgeons' Dispensing Labels.

Members of the Medical Profession requiring gummed Dispensing Labels, either in their own practice or for use in Hospitals, Dispensaries, Unions, &c., are respectfully informed that BOWLES and SONS are prepared to supply Labels of that description, well printed on superfine cream post paper, cut ready for use, in any quantity, and at reasonable prices.

BOWLES and SONS solicit particular attention to their NEW ENGRAVED LABELS. Plates for many of the leading sorts they have already engraved, and will continue to add others from time to time, as may be required. The price is 4d. per 100, or 8s. per 1000.

Letter-press Dispensing Labels, 2d. per 100, 1s. 8d. per 1000; ditto, with name and address, 3s. per 1000.

A List of the DISPENSING LABELS which BOWLES and SONS keep in stock forwarded to any part of the kingdom, post-free.

CHEMISTS' LABELS, &c., in great variety. Catalogues and Book of specimens may be had on application.

BROUGHAMS.

**Kinder, McNaught, and Smith,**  
MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in. . . . .	7 1/2 cwt. . . . .	5 Guineas.
3 ft. 6 in. . . . .	8 cwt. . . . .	95 Guineas.
3 ft. 7 in. . . . .	9 cwt. . . . .	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS at the Warehouse, 2, Upper Copenhagen-street, Barnsbury-road, Islington, London, N. E. and H. Harris beg to submit the following prices, for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

6 & 8 oz., any shape, plain or graduated	3s. per gross.
3 & 4 oz., do. . . . .	7s. 6d. do.
1/2 oz. white moulded phials	4s. 6d. do.
1 oz. do. . . . .	5s. 6d. do.
1 1/2 oz. do. . . . .	6s. do.
2 oz. do. . . . .	7s. do.

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London. Bankers: Union Bank of London.

## Williams and Son's Pure Glycerine

SOAP. Analyzed by Dr. Hofmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.  
THE MEDICAL TIMES AND GAZETTE.  
THE BRITISH MEDICAL JOURNAL.  
THE MEDICAL CIRCULAR.  
EDINBURGH MEDICAL JOURNAL.  
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, &c.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

ESTABLISHED 1830.

## M. and R. Jewell beg to express their

thanks for the encouragement they have received from the Medical Profession, and hope for a continuance of their favours at their Medical Glass and Bottle Warehouse, 53, Howland street, Tottenham-court-road, where an extensive Stock is always kept on hand, at the lowest prices. Measures, Stopped Bottles, Pedestal Mortars, &c. etc. Orders punctually attended to. List of prices forwarded post free.

## The Medicated Cod Liver Oils,

comprising  
OLEUM MORRHUÆ CUM QUINA.  
OLEUM MORRHUÆ CUM FERRI IODIDO.  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

EFFICACIOUS PREPARATION BY  
SAVORY and MOORE, 143, New Bond-street.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS, assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.
6 and 8 oz., any shape, plain, or graduated	8	0 per gross.
3 and 4 oz. ditto	7	6 do.
1/2 oz. Moulded Phials	4	6 do.
1 oz. ditto	5	0 do.
1 1/2 oz. ditto	6	0 do.
2 oz. ditto	7	0 do.

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

## Wines from South Africa.—Port,

SHERRY, etc., TWENTY SHILLINGS PER DOZEN. These Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices. A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy and the opinion formed is that they are worthy of being patronised."—Clerical Journal, October 22, 1857.

EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen. Examine Carefully. Country orders must contain a remittance. Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

## For Use Medicinally, in all Diseases of

the STOMACH, CHEST, etc., for dressing and deodorizing cancer and all foul wounds, for purifying sick chambers, for embalmment of the dead, etc., Mr. JASPER ROGERS'S PATENT CARBONIZED PEAT MOSS. The various kinds of powder and lozenges are prepared solely by the Health of Towns Improvement Company. Sole Wholesale Agent, Joseph G. Thompson, Esq., 2, Adelaide-place, London-bridge, London, E.C., and 5, Donegal-square, Belfast; sold by Mr. W. L. Bird, Pharmaceutical Chemist, 42, Castle-street, East, Oxford-street, W.; Mr. J. Johnson, Chemist, 123, Upper-street, Islington, N., London; Messrs. Bewley and Evans, Dublin; and all respectable Chemists. See extracts from publications on the subject, with the preparations.

## The Best Food for Children, Invalids,

and others.—ROBINSON'S PATENT BARLEY, for making Superior Barley-Water in Fifteen Minutes, has not only obtained the Patronage of Her Majesty and the Royal Family, but has become of general use to every class of the community, and is acknowledged to stand unrivalled as an eminently pure, nutritious, and light food for Infants and Invalids; much approved for making a delicious Custard Pudding, and excellent for thickening Broths or Soups.

ROBINSON'S PATENT GROATS, for more than thirty years, have been held in constant and increasing public estimation, as the purest farinæ of the oat, and as the best and most valuable preparation for making a pure and delicate GRUEL, which forms a light and nutritious supper for the aged, is a popular recipe for colds and influenza, is of general use in the sick chamber, and, alternately with the Patent Barley, is an excellent Food for Infants and Children.

Prepared only by the Patentees, ROBINSON, BELVILLE, and CO., Purveyors to the Queen, 64, RED LION-STREET, HOLBORN, LONDON.

Sold by all respectable Grocers, Druggists, and others, in town and Country, in Packets, at 6d. and 1s., and in Family Canisters, at 2s., 3s., and 10s. each.

## Bank of Deposit, Established A.D. 1844.

3, PALL MALL EAST, LONDON.

Parties desirous of investing Money are requested to examine the Plan of the Bank of Deposit, by which a high rate of interest may be obtained with perfect security.

The Interest is payable in January and July.

PETER MORRISON, Managing Director.

Forms for opening Accounts sent free on application.

## ORIGINAL LECTURES.

## GULSTONIAN LECTURES FOR 1858.

AT THE

Royal College of Physicians.

By JOHN ADDINGTON SYMONDS, M.D. F.R.S.E.  
Consulting Physician to the Bristol General Hospital, &c.

## ON HEADACHE.

## LECT. I.—Continued.

It is an interesting but a difficult investigation to ascertain the mode of production of some of these sympathetic pains in the head. Here, for instance, is a question. What is the cause of a so-called bilious or sick headache in a person who suffers such an attack once in a year or so? In him there cannot be any great susceptibility on the part of the cerebral nerves, or it would occur oftener. But what is the course of events when it does occur? We need not stop to ask whether it is some imperfectly chymified substance in the duodenum, or some depraved secretion which begins the mischief. We will assume it to be some disturbing impression on the nerves of the alimentary tube.

This impression may or may not produce a sensation of indigestion before the headache. If it does, we might suppose that the impression has passed by extension from the part of the sensorium in relation with the nerves of the stomach to that which is in relation with the nerves of the head, and that the pain is, so to speak, reflected on the latter nerves. If this is the course, I think it must be presumed that there must have been some previous disposition in the centres related with the nerves of the brain to be so affected.

I doubt if this hypothesis is so tenable as the supposition that the impression is communicated along the sympathetic chain to the nerves of the brain, and there excites the disturbance.

Whatever may be the function of the sympathetic nerves as to sensation, motion, and reflex action, it is impossible to observe their intricate nexus, as well as their distribution, without suspecting that one part of their duty must be inter-nuncial between the viscera, and that they must be the agents of that consensual operation without which the functions of organic life could not long continue.

Order in time must be as necessary in the human microcosm as in the macrocosm of the universe. Were the processes of digestion, sanguification, respiration and circulation, to go on independently, the vital machinery would soon come to a stop. The heart beats at definite intervals, the respiration keeps a proportionate time, food should enter, and its residue leave the system at regular periods. But the rates are perpetually changing, from the variations of daily or even hourly life, and the changes must be announced from one part to another, in order that the requisite adjustments may take place. Without entering, however, more minutely into speculations as to the final cause of the intimate nervous connexions of the viscera, we may content ourselves with pursuing the way of exclusion. The cerebro-spinal nerves mixed up with the ganglionic nerves account for as much of sensation and emotional influence and reflex action, as we meet with in the viscera. The contractions of the muscular fibres of organic life probably have special relations with true ganglionic fibres and ganglionic centres, uni-polar, bi-polar, etc. Still there are a large number of plexuses, and nerves entering and departing from those plexuses, whose function is scarcely accounted for, unless we infer that their office is to keep up a connexion of some sort between the viscera.

A general survey of the ganglionic system and the connecting nerves impresses us with the unity of the whole system. But without the *a priori* assumption that organs so connected must work together, we have strong *a posteriori* evidence of the connexion in the events of disease. One organ, the variations of whose actions may be considered typical of the rest, is more easily observed than the others. I need not say that I allude to the heart. Much has of late years been done to prove the dependence of its rhythmical action on ganglionic centres. Since these researches I think we can more

definitely understand than ever we could understand before, the readiness with which the rate of the cardiac pulsations is affected by disorders of any organs within the ganglionic chain. The intermittent pulse of indigestion, the alarming rapidity of the heart's action from inflammation of the peritonæum, or the depression of its action from injuries without loss of blood or severe pain—show that this regulating central power of the circulation not only receives tidings of distant organs with great quickness, but also that it is seriously perturbed by them. There is every reason from analogy to infer that although we have not such ready means of noting the influence of other ganglionically connected organs on each other, as in the case of the heart and the other viscera, yet that communications are continually going on in health, and that the same links of communication produce the association of morbid phenomena. That the connexion in health is quite irrespective of sensation is obvious from the fact that in perfect health individuals may live for long periods of time unconscious of internal viscera, and therefore that their harmonious action had not been indebted to sensation. The sensory nerves of the viscera seem to have no other function than that of denoting unusual states of the organs. But if this be the function, the question arises, What possible good can accrue from the transference of the sensation from the sick organ to one that is well, or comparatively so?—a common enough occurrence in sympathetic disorders. The good would certainly appear to be beyond our discovery, but we may endeavour to learn the course of transmission. Do the sensory fibres convey the impression direct to the sensorium? and before its conversion into a sensation is the impression transferred to another part of the sensorium related with sensory ganglionic fibres from some other viscus? Is the impression which has been made on the gastric nerves by a lump of ice, allowed to pass over the encephalic cells related with those nerves without being converted into a sensation, while on reaching the cells related with the sensory fibres of the first branch of the fifth nerve it causes a state which is felt in this nerve as neuralgia? Is this the probable route? or is there not another equally probable? If we admit that impressions are exchanged between the different ganglia, may we not conjecture that the impression made by the ice on the gastric nerves, instead of running along the nearest *rami communicantes* to the spinal ganglia, and thence up the sensory tracts (whatever they are) to the sensorium, or if you please by the more direct course of the vagus; instead of either of these courses, I say, may we not conjecture that the impression takes its route up the chain of sympathetic ganglia, making no disturbance till it reaches the ophthalmic ganglion, which being in a susceptible state undergoes a certain change, which change on being imparted to its sensory nerves, excites a sensation of pain referred to the parts over which the sensory nerves of that ganglion are distributed? In this hypothesis I assume the ophthalmic ganglion to be predisposed to disorder, because an organ sympathetically affected with disease implies a readiness for disease in some part of its structure. A sympathetic disorder is, so to speak, not forced on the sympathising organ—it is invited by the readiness of the latter to take offence.

Let us endeavour to apply some of these considerations to another particular instance bearing on our immediate subject. A gentleman had for many years been liable to attacks of headache on the slightest provocation. Long-continued intellectual exertion, the excitement of an agreeable party, a journey, any error of diet, would inevitably lead to an attack of headache. During the same period he suffered at different times from pain in his teeth, which decayed rapidly, and at last were removed, and replaced by false ones. This change happened more than a year ago, and since that time he has been almost exempt from pain of the head. In other respects his health and mode of life have been unaltered. What was the connexion between the diseased teeth and the headache? The morbid impressions on the ganglionic fibres of the fifth pair might, without any stretch of hypothesis, be reasonably presumed to induce a morbid state of the Gasserian ganglion, whether the impressions on the sensory fibres did or did not reach the sensorium, and induce a painful sensation referred to the teeth. The Gasserian ganglion is connected by marked fibres with the cephalic ganglion, from which a large number of nerves pass to the cerebral arteries. The cephalic ganglion probably partook of the morbid condition of the Gasserian, and hence might have arisen so susceptible a state of the ganglionic nerves of the brain,

that they may have become disposed to ache under the influence of impressions which, without the predisposition in the nerves, produced in the manner I have described, would have had no effect. It seems to me that if this explanation cannot be accepted, there is no alternative but the supposition that morbid impressions on the dental nerves (not creating pain in those parts) arriving at the central extremities of the nerves, are passed on to that part of the sensorium which is related with the sensory fibres of the ganglionic nerves of the brain, and maintain in that part of the sensorium a morbidly susceptible condition; and that this condition is brought into such action as constitutes pain, whenever the said part of the sensorium receives impressions transmitted from nerves which have been offended by causes acting directly upon them in the brain itself, (as in over-study or anxiety), or when it has received like disturbing impressions from the nerves of other parts of the ganglionic system.

I confess that the first of these views which I have ventured to propound is the one that seems to me more admissible. The course of communication traced in that survey is more direct, and involves less complexity of causation.

I should feel myself to be taking an unwarrantable liberty were I to occupy the time and attention of such an audience as that which I have the honour of addressing, with hypothetical suggestions if the case would admit of a theory. We have not the means of subjecting ganglia and their nerves to satisfactory experimental observations in reference to sensation. When the vivisector has made his way to the base of the cranium externally and internally, though he might obtain satisfactory information as to the conduits of motor influence, I know not how it would be possible in the midst of such tearing and severing of tissues to determine degrees of sensation, which can only be demonstrated by cries or quiverings.

Allow me to try the hypothesis by another example. A gentleman, after playing at bowls one evening, awoke in the night with slight hæmoptysis. The source was referred by his own feelings and his physician's examination to the upper lobe of the right lung. Whether or not a tuberculous nodule was the nucleus of the disease, there was evidence for a short time of consolidation of a portion of the lung in the right infra-clavicular region, and in the same part pain was felt for a long time afterwards, when the patient laughed vehemently or made any strong muscular exertion. But after awhile he observed that pain would occasionally come on in the same part whenever his stomach was at all deranged, and that it would subside after a slight eructation of wind. What was the chain of events in the production of this obviously sympathetic pain? Was the morbid impression which had been made by gas in the stomach on the gastric nerves, transmitted by sensory nerves to the sensorium, and instead of being transformed into a sensation in the part of the sensorium related with the gastric nerves, passed on to the central cells related with the sensory nerves belonging to that portion of lung which was formerly diseased? Or is it not more probable that the gastric impression was transmitted by ganglionic nerves to the pulmonary plexus belonging to the spot of lung in question, and that the impression acting on the morbid susceptibility left in that plexus by old disease, excited in it another impression which having been transmitted to the sensorium produced a sensation referred to the lung.

There is, however, another element to be considered in that curious process by which, when impressions are being made on many sensory nerves, some in particular will be converted into sensations, and which may easily lead to a fallacy. It is a familiar fact that amid the din of confused sounds in a street, or at a dinner party, the only auditory impressions which become sensations that is, which are presented to the consciousness, may be the words of a friend in colloquy. The cause of this appears to be simply the predominance given to one cluster of impressions by the desire, or the compulsion of the will, in other words, the expectant attention. If of two impressions, starting severally from the gastric ganglionic centre, and its related pulmonary centre, one is more intense than the other, it will become the sensation perceived in the sensorium. Or supposing the intensity to be equal, the prevalence may be determined by the expectant attention. If, for example, the pulmonary impression has been linked with apprehensions as to the nature of the illness, or with previous suffering, it will be perceived to the exclusion of the gastric.

This subject of morbid sympathy as to sensation may,

perhaps, be still further elucidated, if we consider the sympathy between the tegumentary surface and the internal organs. What, for instance, is the order of events in catching cold, in the common occurrence of a catarrh? A person liable to such attacks may have been standing at a corner of a street, or at an open window, conversing with a friend. According to the degree of interest in the conversation, he may or may not feel chilly; but in twelve or twenty-four hours he has the symptoms of incipient catarrh. What has happened during that period of incubation? What did the current of cold air do to him? It may be said that the insensible perspiration was interfered with, and that matters were thereby retained in the blood which ought to have been eliminated; and that the blood thus contaminated excites disease in any predisposed organ—the Schneiderian membrane, for instance. This may be the case; but another view might present itself. It might be inferred that an impression has been made on the nerves belonging to the cutaneous blood-vessels, reaches the ganglionic centres, and in its further diffusion extends to the grey ganglionic nerves belonging to the blood-vessels of the Schneiderian membrane, and, through them, so alters the circulation and secretion of the membrane as to produce what is called catarrh. The one view seems at least as likely as the other. But suppose the cold to have operated on some limited portion of the body—say the scalp; or suppose the outward cause to have been damp ground operating only on the feet. It is not easy to presume, in this case, a general defect of elimination. The more probable presumption is, that an impression is made on the nerves belonging to the blood-vessels in the skin, and that they transmit the impression to the visceral ganglia, and disturb such parts as are most prone to disorder.

Or we may take another case for investigation. I have a patient who frequently suffers from severe attacks of headache, and who tells me that one of the most frequent causes is driving in an open carriage in a cold wind. She has no general chill, for she is well clothed, but some morbid impression must be made on the face. In a few hours, the headache comes on. There is here no general interference with elimination, but an impression is made on the skin of the face, which may be transmitted to the Gasserian ganglion, and thence to the cephalic, or it may travel by the route of the arteries to the nerves of the brain. But the road which the sympathy travels may be traced in the reverse direction. Thus a patient is the subject of headache, attended with heat of the scalp, dilated and with throbbing temporal arteries. Cold is applied to the forehead and scalp, and the pain is lessened or removed. How is it thus sedative to the nerves of the cerebral vessels? Its operation on the vessels of the scalp is to cause their contraction; and I presume that this is effected by its operation on the vascular nerves. The impression on them transmitted to their ganglion and plexus must reach the nerves of the brain. We cannot think that the cold penetrates the bony case, and so reduces the vascular disturbance within it; or should any one think that this is not impossible, let us suppose that instead of cold lotions, leeches have been applied. No influence is in this way transmitted through the cranium; the quantity of blood lost is too small to affect the heart or the general circulation, and it is a clear case of sympathy. The relief is afforded here unequivocally through the blood-vessels and their nerves, the latter nerves being the only media of communication between the vessels of the scalp and the vessels of the brain and pia mater, whatever communication may be traced between those of the scalp and the cranium and dura mater. An analogous train of argument might be pursued as to the action of anodynes applied to the surface.

The phenomena of a *coup de soleil* also illustrate the principle; for unless it be thought that the sudden elevation of temperature in the scalp is extended to the cranium, and thus directly irritates the vessels of the membranes and the surface of the hemispheres, there seems no other way of tracking the influence than that which I have already pursued, along the nerves of the external blood-vessels to those of the carotid plexus.

*Cerebral Circulation.*—Having thus far considered the relation which painful affections of the head bear to impressions on distant nerves, let us turn our attention to their connexion with the cerebral circulation.

The intimate connexion of the nerves of the brain with its blood-vessels, enables one to account for the difficulty which is often presented to our diagnosis—that of distinguishing the

pain which is purely nervous, from that which is the effect of vascular disorder. The peculiarity of the intra-cranial circulation enhances the difficulty; for though the researches of Dr. Burrows have settled the question as to whether the quantity of blood in the vessels can vary, having proved that it is variable, yet the nature of the outward barrier indicates plainly that the compression of the vessels, and consequently of the nerves, must at times be very considerable. Suppose the nerves to be in a normal state, the pressure of distended vessels may occasion pain, as in the inflammation of the pulp of a tooth. Or suppose the nerves to be hyperæsthetic, very slight changes in the force and the volume of the circulation will distress them. The aggravation of a nervous headache by palpitation, by interruption to the venous circulation, in coughing, straining, or other muscular exertion, must be familiar to most persons. I have just supposed the case of the nerves being in a normal state, and then distressed by the hydrostatic pressure; but, on consideration, I doubt whether pain is ever due to simple vascular distension, unless the latter has been extreme and long-continued.

It is difficult to find a combination of circumstances exactly like that of the vessels and nerves of the brain. Some resemblance may be found in a limb compressed by an article of dress, as a foot by a tight shoe, which in the evening, under the influence of heat and long dependence, begins to swell. The pressure of the shoe makes the swelling painful; but here, again, there is a want of strict similarity. For the pain comes from the superficial nerves of the skin, which are directly compressed. The pain is not like that which ensues when the vascular nerves only are affected. That mere compression of healthy nerves by their distended vessels should occasion pain, is rather negated by the freedom from pain during violent muscular exertions and strains, which put the vessels of the head under the highest degree of pressure. And again, when the accumulation of blood takes place in the other direction, whether attracted into the capillaries by unusual functional exercise, or injected into them by emotional excitation of the heart, or by the more composite influence of alcohol, there is often an entire exemption from pain, and in the latter instance a feeling of great enjoyment. I think it may be inferred that when fullness of the vessels gives rise to pain, there must be an accompanying or preceding unhealthy state of the nerves of the part, or that the congestion must have been long continued enough to beget such textural disorder as the nerves will necessarily partake of. In inflammation the nerves are for the time injured by the changes in which the process consists, as well as by the first action of the exciting cause.

The headache which follows an epileptic paroxysm, and that which attends or ensues on prolonged dyspnoea, or violent fits of coughing, might seem to be examples of pain occasioned by simple disturbance of the brain-circulation;—but the latter cases are exceptional; that is, it so often happens that both long-continued dyspnoea and cough occur without producing headache, that we cannot but infer that some nervous element must be introduced into those cases in which pain attends upon difficult breathing and cough. As to epilepsy, though we have much to learn respecting its pathology, yet a paroxysm presents unambiguous evidence that the vessels are enormously strained; and the pain after the attack and the functional disturbance of the brain bear a direct ratio to the severity and frequency of the attacks.

It was while I was considering the relation of headache to altered states of the circulation in the brain, and speculating on the possibility that the duration of a fit of headache might be connected with the time requisite for the adjustment of the disturbed balance; and especially for change in the distribution of the cerebro-spinal fluid, which has been supposed to play an important part in such adjustments,—it was with the view of confirming or correcting this supposition that I determined to make some experiments on animals. In the performance of these I had the valuable assistance of my friend, Mr. Michell Clarke, a gentleman well versed in anatomy, and expert in operating.

If the cerebro-spinal fluid replaces blood withdrawn from the intracranial vessels by gravitation, or if, conversely, the recession of the fluid makes room for congestion of those vessels, it appeared to me that were an animal kept some time in a certain position, the cerebro-spinal fluid ought to be found accumulated either in the cranial or in the vertebral

cavities; if erect, in the ventricles and subarachnoid space of the brain; if inverted, in the theca vertebralis.

Three rabbits were selected. One was suspended by its ears and fore-legs, another by its hind-legs, a third was kept for comparison.

The two suspended rabbits were poisoned with prussic acid after about half an hour, their positions having been strictly maintained. The post-mortem examination was made immediately, and with the bodies kept steadily in the same position.

In the rabbit inverted during suspension the eyes were very prominent, and the membrana nictitans was congested (but there had been no manifestation of distress during life). The vertebral canal was first laid open. All the tissues in the lumbar and dorsal region were bloodless; those of the neck and cranium were gorged with blood; the membranes and the substance of the spinal cord in the lumbar and dorsal regions were quite pallid. In the cervical portion of the theca there appeared a slight accumulation of sanguinolent serum. On opening the cranium, the bony tissue was full of blood; the meninges were highly congested, and the puncta sanguinea in the cerebral substance were numerous and strongly marked. There was no serous fluid in the ventricles, and none external to the convolutions.

The rabbit which had been suspended by its ears and fore-legs was of course examined in an erect posture. The tissues of the head, neck, and back were exsanguine; but those of the lumbar region were in an opposite condition. When the cavities were laid open, the membranes of the spinal cord in the same region were found injected, while those of the brain and the vessels of the brain substance were extremely pallid. Serous fluid was anxiously and carefully looked for in the ventricles and between the convolutions, and at their base, but none was found.

The third rabbit was poisoned with prussic acid, and examined immediately in the horizontal position. There was a pretty equal distribution of blood, and nothing remarkable was observed, excepting the absence of anything like cerebro-spinal fluid, either in the cranial or in the vertebral cavity.

These experiments, while they entirely confirmed the observations and conclusions of Dr. Burrows, as to the production of an increased or lessened quantity of blood in the brain by gravitation, were negative as to any adjustment affected by cerebro-spinal fluid.

I thought it well therefore to repeat the experiment on two full-grown and very strong rabbits. They were suspended for an hour. The rabbit which hung by the ears and fore-legs was found dead. The other, quite vigorous, was poisoned with prussic acid. They were examined with the same results, excepting that in the inverted animal there was not the same appearance of sanguinolent exudation in the cervical portion of the theca vertebralis which had been found in the first case. The rabbit which had died suspended by his ears and fore-legs was examined with particular care and interest. No serous fluid was discoverable in the ventricles, and none beneath the pia mater—none in any part of the cranial cavity. But the membranes and brain-substances were absolutely blanched. The appearances corresponded with the plate in Dr. Burrows's work, representing those of a rabbit bled to death.

As this observation was interesting in proof of the fatal effects of a posture which diverted blood from the brain, it was repeated on two other rabbits. One was suspended by the ears and fore-legs, the other by the ears only. Death occurred a few minutes earlier in the former than in the latter case. The appearances within the cranium were similar to those described in the former instance.

In order to meet the supposition that the animals might have been distressed by the weight of the body, and the strain on the ligaments of the neck, the weight had been taken off by a support applied to the haunches.

Thinking it desirable to ascertain whether the inverted position would occasion death, if continued longer than in the cases of the animals suspended in that posture, a strong middle-sized rabbit was hung up by his hind-legs, and kept in that situation for more than four hours. After being cut down, he looked for a moment astounded, then gave his head a shake, and seemed to have recovered his self-possession. He was in fact quite well, and began to feed heartily.

Rabbits are known to hold their lives on a slighter tenure than do many animals. We thought it right therefore to try the

effect of the erect posture in one of another order. A cat, being proverbially tenacious of life, was selected. Mr. Clarke found it difficult to keep her head constantly upright. She died in three hours and a half. The brain and its membranes were perfectly bloodless, but there was no fluid in the ventricles, nor under the pia mater, nor in any part of the cranial cavity. Neither could more than a very few drops be discovered in the vertebral cavity.

Whatever may be the physical agency by which the brain deprived of its blood is still capable of filling its bony case, the proof given by the experiment of the degree to which blood may be drained from the cerebral vessels by posture only, has, it seems to me, some considerable value. We see that, independently of the nutritive relation between blood and neurine for the performances of brain function, one of the conditions under which this function is performed is a certain amount of pressure, a greater or less amount of which may produce distressing or even fatal results. In the rabbit the circulation is not so arranged as to maintain even for a short time an adequate supply to the brain under the disadvantageous circumstances of erect posture. While the egress of blood is helped by gravitation, the afflux is to be kept up by the exertion of a heart not vigorous enough to overcome the difficulty presented by gravitation. The heart soon becomes further weakened by the reflected influence of that very state of the brain which its own incapacity has engendered, and fatal syncope is the result.

The fact teaches us also how important to man, with his "as sublime," is a sufficiency of strength in his left cardiac ventricle. It may be that in him there is a larger amount of cerebro-spinal fluid normally existent, and that he is furnished with adjustments for his greater variety of postures. But still nothing is more to be apprehended than the result of diminished afflux and pressure, from a failure of the cardiac impulse. And the observation is, I think, confirmed by all clinical and pathological experience.

I need scarcely say that in these experiments it was a surprise to Mr. Clarke and myself that no appreciable quantity of fluid should have been found corresponding to the cerebro-spinal fluid, though it was carefully looked for. Mr. Clarke was at the pains of examining under every precaution the vertebral and cranial cavities in a cat, and in dogs poisoned with prussic acid, but with the same negative results. The examination of a dog was made in the presence of Mr. Henry Clark, an accomplished anatomist, and myself. The whole quantity of fluid collected on bibulous paper from the theca vertebralis, the ventricles of the brain, and the cranial cavity, amounted at the most liberal computation to no more than seven drops.

It is not difficult to reconcile these negative results with the fact that one finds more or less serous fluid in the cranial and spinal cavities of the human subject, because the latter is always examined several hours after death, and when there has been abundance of time for the transudation of fluid in these as well as in other serous cavities. And, *a priori*, a larger proportion might be expected from the exceeding vascularity of the pia mater, which represents sub-serous cellular tissue. But it is more difficult to explain the absence of the fluid in the animals examined by us, when we consider it in relation to the experiments of Magendie, Cruveilhier, Ecker, and others, on the living animal. It would be presumptuous, as it is unnecessary to question the accuracy of such practised observers. And without other evidence I should come to the conclusion that the presence of true cerebro-spinal fluid is confined to the living animal, and that when the quantity of blood in the vessels is diminished by death, the fluid passes into them by endosmotic action.

But I have before me the notes of an experiment made by Mr. Clarke on a living dog, previously rendered anæsthetic by chloroform, which fully corroborated those of Magendie and Cruveilhier. The dog was of smaller size than that which was examined after death, yet nearly sixty drops escaped from the puncture through the occipito-atloid ligament, though from a dead animal of the same size the sum-total of serous fluid obtained from ventricles, cranium, and theca vertebralis amounted at the outside to seven drops only.

I have already said that it also remains to be explained how the brain, all but emptied of blood, still fills the cranial cavity. Two cats were killed, especially with a view to this point. The brain was drained either by posture, or by division of the cervical vessels, but on opening the cranium the dura mater

was found as tense as if the vessels had been full of blood, and yet no serous fluid was discoverable. As there is no ground for attributing resilience to the cerebral substance, we are forced to speculate upon the possibility of some interstitial fluid or serous halitus. As the experiments have proved that the cerebro-spinal fluid of the living animal is not to be found after death, can it be that this fluid instead of being extra-membranous becomes interstitial? Or is there some æriform substance in the vessels, such as prevents the coats of many of the arteries from collapsing after death, though they no longer contain blood? I have already suggested some experiments to Mr. Clarke in elucidation of this subject, some of which he has already performed, while others are still in progress.

#### *Dissection to determine presence of Cerebro-spinal Fluid in a living Dog, Feb. 17, 1858.*

A small dog, between three and four years old. Chloroform was administered. There was a good deal of difficulty in keeping him under its influence, but it was managed pretty well throughout.

The post-occipito-atloid ligament was exposed, and dissected off. The arachnoid membrane bulged out, thin, and transparent-looking. With each inspiration it subsided, to become more prominent with every expiration. There was no movement synchronous with the action of the heart.

Upon puncturing the arachnoid, a considerable quantity of a limpid fluid, which looked just like water, escaped through the opening, and rapidly filled up the bottom of the space dissected out between the muscles. For a little time it came forth continuously, but afterwards a little escaped with each expiration, and the flow ceased altogether. Then the medulla oblongata became evident, and it was seen to subside with each inspiration—and to rise with each expiration. The medulla oblongata also showed movements synchronous with the pulsations of the heart.

The quantity of fluid that escaped I estimated at from forty to sixty drops; but one could not see its rising and falling, and the sub-arachnoid space accurately filled with it, without feeling convinced that it fulfils an important office.

The wound was sewn up, and the dog recovered from the anæsthesia; and about a quarter of an hour afterwards was sensible, and came when he was called; but tottering and paraplegic as to his hinder parts.

## ORIGINAL COMMUNICATIONS.

ON THE

### OPERATION OF IRIDECTOMY, OR EXCISION OF A PIECE OF THE IRIS.

AS RECOMMENDED BY DR. GRAEFE OF BERLIN (a), AS A MEANS OF CURE IN VARIOUS DISEASES OF THE EYES, ESPECIALLY CHRONIC IRITIS, IRIDOCOROIDITIS, AND GLAUCOMA.

By T. WHARTON JONES, F.R.S.

Professor of Ophthalmic Medicine and Surgery in University College, London, &c.

AND

WILLIAM MACKENZIE, M.D.

Surgeon-Oculist in Ordinary to Her Majesty in Scotland, Lecturer on the Eye in the University of Glasgow, &c. &c.

Dr. Graefe maintains that repeated relapses of iritis are in most cases owing to *Synechia posterior*, or the adhesions formed between the iris and capsule of the lens by exuded lymph, and not to any constitutional or other general cause. Accordingly, the dangers of injury to the sight in acute iritis, he alleges, have been much diminished since his introduction of the

free use of atropia (its application to the eye every five minutes) in the treatment of that disease. For, says he, neither the antiphlogistic and mercurial treatment, nor the other methods which have been recommended, were found sufficient to cure iritis completely. They are, he admits, important and indispensable adjuvants, but contends that mydriatics are the only certain remedy!

It seems to us that this is a very perverted view of the matter. We consider that the tendency of iritis to relapse when it does occur, is in a great measure owing to the inflammation having been wholly neglected or ill-treated at the first, the treatment interrupted before the cure was complete, or the patient exposing himself anew to the exciting causes. As a neglected conjunctivitis leaves the conjunctiva very susceptible of new attacks of inflammation, so an iritis, which has been allowed to run its course unchecked, or has been imperfectly cured, engenders a liability to relapse from the slightest cause, and that whether synechia posterior have become established or not. It is to be admitted, however, that the liability to relapse is, in general, greater when there is synechia posterior; but this is not in consequence of the synechia itself; the adhesions are merely an evidence of the attack of iritis, which led to the exudation of lymph in such a degree as to establish permanent synechia posterior, having been very severe and obstinate, either naturally or from neglect or bad treatment. Synechia posterior, therefore, instead of being a cause of relapse is an effect of the same causes as that on which the tendency to relapse depends, viz. the ill-cured inflammation.

When Dr. Graefe says that he has found neither the antiphlogistic and mercurial treatment, nor the other methods which have been recommended, along with, he ought to have added, the usual moderate employment of belladonna or atropia, sufficient to cure iritis completely, we attribute the failure, not to the inefficiency of the plan, but to Dr. Graefe's unskilful application of it. Dr. G. must know quite well that wide dilatation of the pupil is no preventive of the exudation of lymph, and consequently of the establishment of synechia posterior, and therefore that mydriatics alone cannot be, even if synechia were the essential cause of relapse, the certain remedy he pretends. Dr. Quadri (b) of Naples, who lately visited Berlin, tells us that he watched some of Dr. Graefe's patients under treatment for iritis by means of the free exclusive use of atropia for the purpose of preventing or destroying adhesions, and found that the patients, instead of getting better became worse.

Under the use of atropia the pain attending iritis often subsides; an effect Dr. Graefe attributes to the dilatation of the pupil, which may occur at the same time. This, however, is not, we think, the correct explanation of the matter. The proper way of expressing the fact rather appears to be as follows:—The iritis subsiding, the pupil yields to the atropia; and on account of the subsidence of the inflammation the pain abates. It is, at the same time, to be remembered that belladonna has a specific action of relieving the pain. Taken internally in doses of ten or twelve minims of the tincture, it in many cases almost immediately affords relief to pain in or around the eye.

To return to synechia posterior, or the adhesions between the iris and the capsule of the lens:—When there is total synechia posterior without actual closure or obstruction of the pupil with lymph, the communication between the circumferential part of the posterior chamber and the anterior chamber being merely cut off, Dr. Graefe calls the state *exclusion of the pupil*. When, in addition to total synechia posterior, the pupil is actually closed, he calls the state *occlusion of the pupil*. Occlusion thus includes exclusion of the pupil, while the latter may exist without the former.

Though both exclusion and occlusion of the pupil may exist without leading to relapse of the iritis which gave them origin, and although relapse with extension of the inflammation to the choroid, when it does occur, is principally owing to the tendency left by the imperfectly cured inflammation, we do not mean to say that the adhesions of synechia posterior contribute nothing to the relapse and extension of the inflammation to the choroid. On the contrary, we admit the propriety of the operation of iridectomy, or lateral excision of the iris, in cases of mere exclusion of the pupil, for the purpose of re-establishing the communication between the pos-

terior and anterior chambers, and of relieving tension in cases in which the eye shows no disposition to recover itself completely, and especially in those cases in which there is a bulging of the iris towards the cornea. The success of the practice, however, does not appear to be very great. The first case Dr. Graefe gives is as follows:—

The patient, a man. *Left eye* quite blind, somewhat soft, iris bulging towards the cornea, but retracted at the pupil, which was closed by a white membrane. *Right eye* so dim-sighted that large objects only could be seen with it; total synechia posterior; iris greenish, and here and there bulging. This state of the eyes appears to have been the result of iritis with supervening choroiditis. Having tried mydriatics without effect, Dr. Graefe had recourse to the operation of lateral excision of the iris on the right eye. When the section of the cornea was made little aqueous humour escaped, but when the iris was seized and torn with the forceps a quantity of yellow fluid was evacuated. Next day the iris was found no longer bulging forward, and the anterior chamber was re-established. Eight days after the operation the patient could see to count the fingers at the distance of the whole length of the room, and to make out large letters. In the course of four years, the sight went on to improve so much that the man was able to undertake the duties of a situation requiring sure sight.

In similar cases Dr. Graefe states that he has always obtained the following results:—Re-establishment of the anterior chamber; restoration of the natural texture of the iris; no further relapse of the inflammation; considerable improvement of sight. This improvement of sight Dr. Graefe satisfied himself was in most cases owing, not to absorption of the lymph in the pupil, but solely to diminution of the choroidal complication.

Dr. Graefe next performed iridectomy in cases of primary iritis, with exclusion of the pupil, followed by atrophy, in consequence of secondary choroiditis; the iris being at the same time pressed close to the cornea. In some of the first operations, the pupil contracted again to a slit, but there was always a certain improvement in the colour of the iris, and a restoration, though inconsiderable, of the anterior chamber. In some patients, after three or four repetitions of the excision of the iris, a result was obtained which Dr. Graefe says he could not have anticipated. Besides improvement in the condition of the tissue of the iris and restoration of the anterior chamber, the atrophy, if not too far advanced, disappeared. In one case of atrophy of both eyes, which Dr. Graefe had long before given up as incurable, he operated six times; after which, the sight improved from week to week, so that the patient came to be able to count the fingers at the distance of several feet, and to distinguish all large objects, and letters of the largest print, whereas before he had merely a slight perception of light. The iris became almost natural in appearance, the anterior chamber re-established, and the size and consistence of the eyeball more natural. At the same time, there was a somewhat advanced opacity of the lens, and the natural pupil was closed by a white membrane, so that, in short, the patient's degree of sight was in proportion nearly to the state of the refractive media.

Irido-choroiditis requires to be classed under two heads viz., those cases in which choroiditis, with effusion between the choroid and retina, is the primary affection, and the iritis secondary; and those cases in which the iritis is primary, and the choroiditis secondary, and not much developed. In the first class of cases, restoration of sight cannot be expected. It is only in the second class, especially when the perception of light is still strong, and when atrophy of the eyeball is not far advanced, that benefit can be derived from the operation of iridectomy. But the best and surest results are obtained in the cases in which, with total posterior synechia, there is no bulging of the iris.

No doubt of it, we would remark, because these are cases in which the sight being still good, it would be better, perhaps, not to interfere at all. Dr. Graefe, however, is of a different opinion, saying: "It is, indeed, somewhat critical for the young Practitioner to operate in such a case, because the patient still enjoys, for the most part, good sight—often being able to read small print,—and because it is, moreover, not absolutely certain that secondary choroiditis must supervene. If the other eye is already amaurotic, in consequence of the disease, it is proper, notwithstanding this doubt, not to

(b) Relation d'un Voyage Scientifique. Par le Dr. A. Quadri (de Naples). Annales d'Oculistique. Mai, 1857. Bruxelles, 1857.

delay the operation, for the chances of success may be considerably diminished by the supervention of choroidal complication, as also the formation of cataract." (c) Dr. Graefe assures us that there is no fear of the sight suffering from the operation of iridectomy in such cases. We think, however, that the young Practitioner, at least in this country, even if disposed to attempt the operation in such cases, is not likely to be afforded the opportunity of doing so on any patient who has not lost his wits.

In conclusion of this part of his subject, Dr. Graefe affirms that, in the large proportion of cases, the patients on whom the operation of iridectomy has been performed on account of total synechia posterior, have really remained free from relapse of the iritis.

The following are other states of the eye in which Dr. Graefe has performed iridectomy, or lateral excision of the iris, with the results of the operation.

1°. Cases in which irido-choroiditis supervened on separation of the retina from the choroid. *Result.*—No improvement of sight, but an improvement in the organic condition of the eye, which was reflected on the sound eye, so that the use of it was not interfered with. In general, an already formed cataract was disclosed by the opening up of the new pupil.

2°. The cases of irido-choroiditis, commonly known under the names of aquo-capsulitis, iritis serosa, etc., in which there is little or no exudation into the pupil, but in which there supervene opacity and softening of the vitreous body, with tremulous iris, etc., and eventually separation of the retina from the choroid, cataract, etc. *Result.*—It was only in old and desperate cases of the kind that Dr. Graefe had recourse to the operation; and, as he performed it no more than six times, he cannot, he says, form any opinion of the probable success of the practice. He feels, however, encouraged to a further repetition of the operation, as in two of the cases he obtained results beyond his expectation.

3°. Sclerotic-choroiditis. *Result.*—In cases of this affection, Dr. Graefe has not witnessed any bad effects from the operation of iridectomy, but he admits that he has obtained no good result, so that he does not feel encouraged to further attempts.

4°. Corneitis, with or without iritis.—Dr. Graefe first performed the operation in those cases of this affection in which it appeared that the formation of an artificial pupil would come to be necessary, but in which, on account of extraneous circumstances, the termination of the corneal disease could not be waited for! *Result.*—The operation, Dr. Graefe says, did not aggravate the corneal disease, but, on the contrary, healing of corneal ulcers and clearing of opacities almost constantly ensued. Dr. Graefe thinks that the benefit derived from the operation was not owing to the mere evacuation of the aqueous humour, for this, he says, is useful only when the puncture of the cornea continues open, so that the aqueous humour may be permitted to drain away for some time. He, therefore, is of opinion that the excision of a piece of the iris is an essential element of the success by diminishing the secretion of the aqueous humour! We cannot help remarking that this assertion manifests great inaccuracy on the part of Dr. Graefe, for every one who has practised the operation of evacuating the aqueous humour in cases of acute internal inflammation of the eye, knows that a single evacuation is often sufficient to check the inflammation, and render it amenable to the remedies which it had before resisted.

5°. In cases of swelling out of the lenticular substance after the operation for cataract by division, or after wounds, in order to prevent the bad effects of pressure on the iris. In some cases Dr. Graefe admits that it is best to remove the lens by linear extraction; (d) but he says that it is occasionally necessary to perform iridectomy instead, before extraction, or at the same time with it. This is especially necessary in cases in which the iris has been prolapsed into a wound of the cornea, and the pupil dragged and contracted. Existing inflammation is no contra-indication.

6°. In cases of extraction of the cataract, when the lens does not readily pass the pupil, and when the iris is conse-

quently injured by pressure, Dr. Graefe performs iridectomy after the completion of the operation.

7°. When one eye is completely blind from chronic iritis, Dr. Graefe recommends the performance of iridectomy in order to relieve the opposite eye similarly affected.

In a case (the patient a girl twenty years old) of sympathetic amaurosis of the right eye supervening on irido-choroiditis, with separation of the retina in the left, Dr. Graefe excised the latter eye according to the method of Bonnet, in the hope of thereby arresting the failure of sight of the other, if not of improving it. The sight of the right eye did improve somewhat, but as no diminution of the morbid appearances observable in it by the ophthalmoscope (viz., excavation of the papilla optica and displacement of the trunks of the retinal vessels) had taken place in the course of three or four months, Dr. Graefe resolved to perform the operation of iridectomy. After this, the distension of the eyeball, he says diminished; and, down to the time he last heard of the patient—a period of seven months—the sight had become no worse.

The excision of the left eye in this case, we think, might have satisfied Dr. Graefe.

We now come to iridectomy in glaucoma.

Considering intraocular pressure, in consequence of an increased accumulation of vitreous and aqueous fluids, indicated by abnormal hardness of the eyeball, the first stage in glaucoma, the question which Dr. Graefe proposed to himself in respect to treatment was—By what method is a diminution of the intraocular pressure likely to be effected?

Dr. Graefe first tried the local application of mydriatics, but without effect. On this proceeding we would remark, that it is not easy to perceive on what grounds any effect in diminishing intraocular pressure could have been expected from mydriatics. The contrary was to have been feared; for the fact is that mydriatics generally impair the sight still more in glaucoma, and this they appear to do by determining constriction of the arteries, and thereby increasing the venous congestion.

Dr. Graefe next tried repeated evacuation of the aqueous humour. The improvement that resulted was in most cases merely temporary. Two patients only appeared to have been permanently benefitted.

At last he had recourse to iridectomy, or excision of a piece of the iris, and in it discovered a true remedy for the glaucomatous process!

#### SUMMARY OF RESULTS OF IRIDECTOMY IN GLAUCOMA.

*In the premonitory stage.*—The occasional dimness of sight never returned; the ciliary pain and chrochey ceased; the muddiness of the aqueous humour disappeared; the presbyopia slightly diminished perhaps; in short the result, Dr. Graefe says, proved most favourable. Admitting this, we nevertheless consider the operation unjustifiable, as we believe that an equally favourable result may as often be obtained from medical treatment, and attention to diet and regimen, with care of the eyes.

*In the acute stage of inflammatory glaucoma, in other words, acute arthritic posterior internal ophthalmia.*—Dr. Graefe's experience of iridectomy in this stage is greater than in the preceding. He has operated on twenty eyes shortly after the outbreak of the inflammation. The severest symptoms subsided after the operation, without the aid of any other means; and in the course of six or seven days the dioptric media had become so clear as to permit of ophthalmoscopic examination. The principal improvement of the sight was manifested in two or three weeks. In all the cases in which the patients were operated on, before the end of two weeks after the commencement of the inflammation complete restoration of sight took place. The second eye, notwithstanding the cure of the first, however, remained liable to be affected in the same manner, and required the same remedy. On this report of the success of iridectomy in the acute stage of arthritic ophthalmia, we would observe that the cases in which well-directed medical treatment, aided by paracentesis of the cornea, of the sclerotic, or of both, so as to evacuate the morbid accumulations within the eyeball, fails, are not likely to be much more benefited by iridectomy.

*In the later period of acute glaucoma, or arthritic posterior internal ophthalmia.*—Though the good effect of iridectomy is most marked in the early stage, it was found still useful in

(c) Archiv für Ophthalmologie, Band ii. Abtheilung ii. p. 228.

(d) By this name, which has been unnecessarily introduced into our Medical literature, Dr. Graefe designates the common operation of extraction by a small section of the cornea, as originally recommended by Gibson, of Manchester, and others.

the later stages of acute glaucoma, or arthritic posterior internal ophthalmia.

*In chronic glaucoma, or chronic arthritic posterior internal ophthalmia.*—Although it was in chronic glaucoma that Dr. Graefe first employed iridectomy, he cannot as yet pronounce a definitive judgment as to the ultimate results of the operation, as the improvement at first obtained has been after two or three months lost.

*In amaurosis, with excavation of the papilla optica.*—In such cases, which, though they present the ophthalmoscopic appearances of excavation of the papilla optica and pulsation of the central artery of the retina, are wanting in the intra-ocular pressure and external characters of glaucoma, no good effect, properly speaking, resulted from iridectomy.

The review which we have now taken of Dr. Graefe's singular application of iridectomy, or excision of a piece of the iris as a means of cure in various diseases of the eye, shows that there is little in it worthy of imitation.

From notices in the Medical Journals (e) we observe that iridectomy has been practised pretty frequently of late at the Moorfields Ophthalmic Hospital.

In chronic glaucoma, not much is said in its favour; but the cases described as inflammatory glaucoma, related by Mr. Critchett, in which he performed iridectomy, are sufficient to confirm Dr. Graefe's reports that good effects result from the operation in the latter disease. Notwithstanding this, the objection remains that the excision of a piece of the iris is a proceeding unnecessarily superadded to a means long known as calculated to give relief, and to which alone the benefit obtained is to be attributed, viz. the removal of the tension by evacuation of the superabundant fluid within the eye.

Dr. Graefe's practice of iridectomy appears to us so opposed to the plainest principles of surgery and common sense, and so little supported by its results, that we must confess our surprise at its having been so eagerly imported into this country. We have no doubt, however, that in a short time iridectomy as a means of treating glaucoma will be abandoned; while the attention of practitioners having been re-directed to the effect of taking off the intra-ocular pressure which plainly exists—not, however, as the primary, but as one of the secondary phenomena in glaucoma—the practice will be revived of more frequently puncturing the cornea and sclerotica in this disease.

## ON INTESTINAL OBSTRUCTIONS, GASTROTOMY, AND ABDOMINAL TAXIS.

By JONATHAN HUTCHINSON,  
Surgeon to the Metropolitan Free Hospital.

It will be readily admitted by all excepting the ultra-sanguine, that it is commonly exceedingly difficult to ascertain the exact seat of an internal obstruction of the bowels. If the vomiting have commenced early, and been severe, we suspect strangulation of some part of the upper tract of the small intestine. If the urine have been deficient, or all but suppressed, this opinion is much confirmed; and should there chance to have been several evacuations per anum subsequent to the setting in of vomiting, it is yet further strengthened. The early occurrence of hiccup, and its severity, are also indicative of obstruction high up. If the vomited matters are only bilious and green, or if, while of brownish colour, they yet remain free from the slightest of fecal odour, we conjecture with some certainty that the obstacle to intestinal action is above the cæcum. If O'Bierne's tube passes readily for a few feet, and, on the use of the enema, a large quantity of fluid is received and retained, we feel certain that the disease is higher up than the sigmoid flexure. On the other hand, if the tube will not pass; if but a small quantity of fluid can be received; if stercoraceous matters have been ejected by the mouth; if, while the constipation have remained obstinate, the vomiting has been less than usual, and the kidneys have acted freely, we arrive at a pretty confident conclusion that the disease is situate in the colon or rectum. In certain cases, again, palpation of the abdomen affords us useful information, revealing a fulness of some particular part, or an

especial tenderness, or an irregularity of contour, or a distinct tumour, by the discovery of which we are led to a correct conjecture as to the site of the obstruction. In our attempts to ascertain the nature of the disease, we possess also certain data which are sometimes present. If the symptoms have set in suddenly, and continued acute, more especially if attended by signs of peritonitis, we assume it as probable that a tight strangulation exists: a knuckle of intestine has most likely passed behind a band of false membrane, or through a loop in the mesentery or omentum, or under an adherent appendix vermiformis. If acute symptoms have suddenly followed violent exertion, as jumping, &c., in a person who never previously had any abdominal ailment, we may guess that a twist of some coil of bowel has taken place. If blood have been passed by stool, the diagnosis of intussusception may be formed, and it will be much strengthened if the patient be a young child, and have previously suffered from diarrhoea or prolapsus ani. If the patient be the subject of external hernia, or have ever had an attack of peritonitis, or have borne children, the probability of the existence of bands of adhesion is much increased. The presence of malignant cachexia, of course, will suggest the existence of a tumour, to the pressure of which on the bowel the obstruction may be due; and here the examination of the abdomen by the hand, and also of the vagina and rectum by the finger, will often convert a conjecture into a certainty. Malignant stricture of the colon or rectum so high up as to be out of reach by the finger, will generally have made its presence known by blood and slime in the stools, and by the narrow riband-like form of the evacuations for some time prior to the occurrence of actual obstruction. But, notwithstanding all these aids to diagnosis, it must be admitted candidly that out of the twenty-five feet of bowel in any part of which the obstruction may exist, and with nearly, if not quite, twenty-five different pathological conditions to which such obstruction may be due, the discovery of the exact seat and the precise disease presents, in a large majority of cases, one of the most difficult problems which can be offered to the Surgeon. With the exception of a very few cases, "guesses at truth" are the best that can be made. Every one of experience must have been present at bedside consultations in which the symptoms were so mixed and so contradictory that it was impossible to arrive at even a plausible conjecture, and in which the rule of *tot homines tot sententia* prevailed almost literally.

I have ventured on these observations on the peculiar difficulties attending this class of cases, in order better to introduce the first question which I propose to submit to the consideration of my readers.

### IS THE PERFORMANCE OF GASTROTOMY FOR ABDOMINAL OBSTRUCTIONS EVER JUSTIFIABLE?

In contending that it is not, I hope I shall be held free from the slightest wish to reflect upon the judgment of the many able surgeons who have resorted to it. The experiment was well worth trying, and it is to them that we are indebted for the facts upon which we now argue against their practice. It is not many months since I had more than half decided to have recourse to it in a case under my own care; and it has been the favourable issue of that case, after the idea of an operation had been abandoned on the ground that the patient would certainly not survive it, which has brought me definitely to the opinion I now entertain. Under the head "Gastrotomy for abdominal obstruction," we may conveniently class all operations involving opening the abdomen, and search for the seat of disease; the less harshly sounding designation of "abdominal explorations" does not in any degree alter the nature of the procedure. Now against its adoption there appear to be the following objections:—

1. *That hitherto it has been followed all but universally by a fatal event.* I am aware of but three cases (a) in this country

(a) These three cases were all of them such as would have permitted of the performance of Amussat's operation, one probably not attended by a tithe of the danger. The first, which is recorded in the "Med. and Phys. Journal," vol. xlv., was that of an old woman, the subject of cancer of the rectum. Her surgeon, Mr. Pring, opened the abdomen after twelve days' complete obstruction, made an incision into the bowel, and established an artificial anus. She lived in that condition for sixteen months. In the second, which will be found at page 25 of the "Edin. Med. and Surg. Journ." Dr. Markland opened the colon by an incision in the left iliac region, in the case of a man who was believed to suffer from invagination of the sigmoid flexure. Recovery with an artificial anus followed. The third is that of a woman, recently under Mr. Adams' care in the London Hospital, for malignant disease, occluding the rec-

(e) Medical Times and Gazette, May 9, 1857, p. 469.—Ibid. January 9, 1858, p. 33.—Ophthalmic Hospital Reports. Nos. 1 and 2.

in which recovery has taken place, and allowing for the fatal cases which have never been published, it has probably been resorted to in not much fewer than fifty instances. In a great majority of these, the patients have sunk within a few hours of its performance, and in several have been with difficulty kept alive to its conclusion. In others, death from peritonitis or from protrusion of the intestines at the wound has occurred. The reason why it should be so fatal in its consequences is not difficult to be found, when we remember that it is an operation universally held unjustifiable until such time as the patient have passed into a state deemed otherwise hopeless; that is, until he have suffered from long existing obstruction, until peritonitis have been set up, the bowel is distended with flatus and fæces, and its coats in all probability on the point of giving way. Cases of spontaneous recovery after very alarming protracted symptoms of obstruction are sufficiently common to prevent even the rashest from venturing to advise gastrotomy, excepting in the very worst class and the extremest stage. Unlike the operation for hernia, and that of tracheotomy in croup, and some others which are always delayed for a certain time in hope of success from milder measures, but which still in themselves do not very materially increase the risks of the case, the laying open of the abdominal cavity is a procedure in itself so fraught with danger and so formidable, that its adoption, excepting as the very ultimate resource of all, is never to be thought of. And yet in this kind of case, the chance of recovery from the shock of such a procedure might have been pronounced from theory, as it has indeed been found in practice, to be infinitely small. A second objection to it is the *extreme uncertainty of diagnosis*. In certain cases, those, for instance, of malignant stricture, and many of those of intussusception, the condition, even when found, is not one susceptible of relief, whilst in others it may be difficult, if not impossible, to find it at all. During the last few weeks these two events have been illustrated in Hospital practice. In the first, a woman was operated upon by a most skilful Surgeon, and after the abdomen had been opened, and a partial exploration without success made, the collapse into which she sank was so extreme as to necessitate the relinquishing of the operation. After death (which followed in a few hours) a knuckle of intestine was found strangulated behind a band of old false membrane connecting the uterus with one ovary. The cause of obstruction was just one of those most suitable for relief by operation, had the circumstances of the case permitted of a more complete search. In the second case, the disease was found to be a malignant stricture of the colon in the upper part of the sigmoid flexure, and was of course not susceptible of any relief. The patient sank within two hours of the operation. In a third case (b), the intestine was found so soft, that it gave way on pressure from the finger; and in a fourth (c), recently under the care of my friend Mr. Savory, fæces also escaped during the liberation of the strictured part. In more than one instance the operation has been performed, and no cause of obstruction found, nor any been discoverable even after death. But there remains yet to be mentioned a third, and by far the most important objection to the operation, and that is—*That although, as shown, these extreme cases almost never recover after gastrotomy, they not unfrequently do if let alone*. I rely chiefly upon the instances of this occurrence, one or more of which will, I expect, suggest itself to the recollection of most of my readers, for the support of the rule of practice it is endeavoured to lay down. If gastrotomy, performed in cases otherwise hopeless, saved one in ten, nay, if it saved one in fifty, we should be compelled in conscience to overlook the

tum. Its particulars have appeared in full in the Hospital Reports of this Journal, about four months ago. It will be seen that in none of these was the operation an exploratory one. It was rather an anterior operation for artificial anus, the cause of obstruction being known. In the Transylvanian "Journ. of Med." for 1856, is the case of a mulatto, aged 20, in whom gastrotomy by the long incision was performed by a Dr. Wilson, after seventeen days' severe symptoms of intestinal obstruction. The bowel gave way during the attempt to liberate it from a sort of twisted knot which it had formed, but he nevertheless ultimately recovered.

This last mentioned is, then, the only case known in which gastrotomy was the only alternative and was successful. On the other hand, not a few fatal cases have been recorded, and many others doubtless left unnoticed. Four or five cases have passed under my own observation in the different London Hospitals during the last six years, and all of them have ended in death.

(b) Medical Times and Gazette, Dec. 1856, p. 620.

(c) Ibid.

injury which the forty-nine fatal cases inflict upon the repute of surgery in the eyes of the public, and to go on with its performance, since it is clearly our duty to preserve life at all hazards of reputation. Coleridge said of another operation, "I think there are only two things wanting to justify a Surgeon in performing the Cæsarian section; first, that he should possess infallible knowledge of his art; and secondly, that he should be infallibly certain that he is infallible." To anyone so accustomed as the surgeon to act upon a calculation of probabilities only, the fallacy of this conclusion of the metaphysician will be apparent. We every day adopt procedures of the utmost importance as regards life and death, without possessing anything approaching to infallible knowledge of their consequences, and we are well justified in doing so. In many instances, to abstain from interference involves far more of responsibility than action itself. But when we find that a reasonable calculation of probabilities is against our meddling the case assumes an opposite character. And such, I am convinced, is the position in which gastrotomy for the relief of abdominal obstruction of unknown nature stands. It is easy for any one who has ever been in a like position to sympathise most fully with the feelings of a Surgeon who has day after day been attending a case of this kind, who has exhausted the resources of medicine, and now stands by the bedside watching his patient writhing in agony, fast sinking from the continued suffering, and unrelieved. The thought that all this is from a merely mechanical lesion, and that, could the part be got at, a single touch with the scalpel might liberate it as effectually as the same result is obtained in an ordinary hernia case, is very likely to suggest a strong inducement to operative interference. Nor would the temptation to resort to a *coup de main* be lessened by the recollection of how well patients bear operations for hernia, how not unfrequently they recover from the more severe ones of ovariectomy and Cæsarian section. We may easily conceive, for we have all of us felt, the strong impulse to use the knife in cases like this, and go right at the source of the mischief. It is, however, my firm conviction that the temptation ought to be resisted, and that it is the Surgeon's duty not to interfere. As already stated, there is no doubt but that every reader will be able to call to mind one or more examples of recovery after circumstances had appeared hopeless. I will relate briefly one such, which not long ago happened to myself.

In the early part of February 1857, I was asked by a gentleman residing in Spitalfields to see a poor woman in whom he was interested, and in whose case he had understood there was something peculiar. The patient was a widow, aged about 37, who had gained a livelihood for herself and family by her needle, and had for long lived very badly. She was now in the third week of an illness of which obstinate constipation and vomiting had been the chief symptoms. The usual remedies had been tried in vain. She was extremely emaciated, and on laying bare the abdomen, so thin were its walls, that the coils of intestines could be easily seen rolling about. The abdomen was distended and tympanitic, but not extremely so, nor was the tenderness on pressure very great. Her pulse was about 100 and very small, the tongue dryish but not much coated. She had never suffered from hernia, and on most careful examination I could not find any signs of protruded bowel, either at the usual sites or through either of the thyroid foramina. The bowels had not acted for sixteen days, and the vomiting had been throughout that time of frequent recurrence. She complained of severe twisting pain, which came on in paroxysms, and during which she would cry out with agony and toss herself about in bed. This pain she referred to the region of the umbilicus. With regard to previous history, she stated that during the last two years she had suffered four attacks similar to the present one. The longest time that constipation had ever lasted at a time before, was two weeks, but on one occasion she had been so ill that her life was despaired of by two surgeons who saw her together in consultation. During the intervals of these attacks it appeared that she usually had fair health, but the bowels were habitually somewhat costive, and she was dyspeptic. She stated, without the term being suggested to her, that during the attack which lasted longest she had vomited matters "which ought to have passed the other way." This account of her previous symptoms was confirmed to me by the medical man who had attended her. Her aspect, though thin and wan to a degree, did not exactly suggest the idea of malignant cachexia, and I was inclined, on the whole, to regard the case

as probably one of intussusception of the larger bowel. Careful palpation of the abdomen had failed to detect any tumour, and on examining with the finger in the rectum only one or two hardened scybala were found in an otherwise empty bowel. It was determined under these circumstances to pursue an opiate treatment, and during the next five days she took grain doses of opium every four hours regularly, with the effect of keeping the pain and the vomiting comparatively in abeyance. She was able occasionally to keep a little milk on the stomach, but in a usual way rejected all she took. Her condition on the whole got worse and worse; her tongue more furred, the pulse more feeble. She had repeatedly had enemata given, but with no other effect than bringing a few small fragments of scybala. During the next week following the opium was given rather more sparingly, and the idea of an atonic distension of the intestines being the cause of the symptoms having suggested itself, I ventured to order the tincture of *nux vomica* in *m.x.* doses three times a day. Small nutrient enemata of beef-tea, eggs and milk, were given throughout at frequent intervals, and she took nothing whatever by the mouth. The paroxysms of twisting pain in the abdomen continued to recur, and her debility increased, her nights being often sleepless. One evening I was called to her, with the statement that she was dying. Since morning she had been vomiting almost incessantly, and the matters ejected had a fecal appearance, and a faint fecal odour. Her pulse was exceedingly rapid, and her hands cool. She could only just speak. We gave her at once a brandy enema, but it did not materially revive her, and about half an hour later I determined to administer chloroform, with a view merely to its stimulant effect. This was done at a time when she was all but dead, the nose and extremities being cold, and she so far unconscious as not to resist the inhalation. It had an excellent effect in rousing her. After a few minutes the senses returned, and the pulse became slower; she regained consciousness, and we got her to swallow an opium pill, and a little brandy. The inhalation was continued, with intermissions, for nearly half an hour. During the night she had repeated enemata, and took a grain of opium every two hours, and in the morning she had rallied, and seemed a little better. It had been quite out of all question to resort to an operation during the state of collapse just described, but while watching her as I believed dying, it was not without feelings of regret that we had not given her the chance, as it is called, afforded by an abdominal exploration. It was now determined at all risks to have her removed to the Hospital, a measure which at great inconvenience had hitherto been deferred on account of her very feeble state. The distance was not great; and having been well fortified with opium, she bore the journey better than might have been expected. In the afternoon of the day of her admission my colleagues, Dr. Ramskill, Mr. Chance, and Mr. Childs, and my friend, Mr. Savory, met in consultation on the case. I believe I was the only one who felt any inclination to venture on the expedient of gastrotomy, all the others being unanimous that she was too much sunken to permit of the operation. My own feeling in favour of it was based on the energy of vital power she had exhibited through this prolonged attack, (now nearly five weeks,) and on the conviction that should such collapse as she had had two nights ago again occur, she would certainly die. We had her placed under the full influence of chloroform, and then again examined the abdomen most carefully, but without result. An O'Bierne's tube was passed up the rectum, and a pad having been placed around the anus to prevent its escape, two large wash-hand basins of warm water were pumped forcibly into the bowel. I should say that prior to the injection I removed by the finger two hardened masses of scybala which had come down into the rectum. The rectum itself was enormously dilated, its coats being very thin; it would have contained two fists at least. The outline of the uterus, etc. could be easily felt through it, and no tumour or induration could be detected. After the enema returned no feces followed. The woman was extremely exhausted by the procedure, and was in an almost dying state when we desisted. Brandy was given freely both by mouth and by rectum. About three hours afterwards a small evacuation was passed. On the following morning my friend Mr. Gay saw her with me; she was still extremely sick and very sunken. Mr. Gay expressed a most decided opinion against gastrotomy, adding, that she would certainly die on the table were it attempted. The treatment

by opium and nutrient enemata was continued. During the next two days she several times passed small quantities of feces, but the sickness and pain continued urgent, and her death was at times hourly expected. On the third morning after her admission a most copious fluid motion passed, and was followed in a few hours by a second. From this time her improvement was slow, but progressive. She became able to tolerate food, and the action of the bowels was free. The quantity of feces got rid of during the next week was enormous. The patient left the Hospital about two months later, having fairly regained her health. Nothing occurred during the convalescence to throw further light on the real nature of the disease. The opinion that it was an example of constipation from sheer atony of the intestinal coats, seems to my own mind one of not the least probable, but several of those who assisted me in the treatment do not by any means concur in it. The extreme dilatation of the rectum, the absence of blood in the stools, etc., are phenomena which I cannot easily reconcile with any other theory.

I have ventured on this narration because I think it affords an excellent illustration of the advantages of waiting. Had gastrotomy been performed I have no doubt that this poor woman's children would now have been motherless.

Among the modes in which the

#### SPONTANEOUS RELEASE OF AN OBSTRUCTION

may occur are the following:—

1. When a knuckle of intestine strangulated by a band accidentally slips back again, or the band gives way.
  2. When an invaginated portion of bowel sloughs off into the cavity of the gut, and leaves its canal free. This I am assured, from the number of specimens which have been brought under my own notice, is not by any means an unfrequent termination of cases of intussusception. It is nature's mode of cure.
  3. When an invagination passes back again.
  4. When a portion of bowel above the strangulation becomes adherent to one below, and ulcerates into it without extravasation into the peritonæum. This is probably rare, but it certainly does occur occasionally in cases of malignant stricture.
  5. When the constipation, etc. has been from impacted scybala or concretions, which later on in the case may get accidentally loosened or dissolved. This is, probably, not by any means an unusual event in the milder class of cases.
  6. When a coil of bowel which has been twisted on itself is turned back in a reverse direction.
  7. When a stricture, either cancerous or otherwise, ulcerates and becomes free.
  8. When a tumour, by the pressure of which on the bowel the obstruction has been caused, either alters its position or diminishes in size.
- To these several other possible, but much more rare, events might, perhaps, be added; but sufficient has been said to fairly introduce the question which it is the main object of this paper to raise, namely, What is the kind of treatment most likely to conduce their occurrence?

#### THE ABDOMINAL TAXIS.

We are accustomed now-a-days to smile at some of the expedients to which, in bygone times, it was the custom to resort, in order to accomplish the reduction of strangulated hernia. We read of one surgeon, that he used to have his patients placed in a wheelbarrow, with the legs passing out behind, and, while some one drew the vehicle rapidly along over a rough road, he followed behind, endeavouring all the time to force back the rupture. Now, it is all very well to laugh at such modes of treatment as this, and with the advantages which chloroform and recent improvements in operating give to the modern Surgeon, he would certainly have no excuse for going back to them. But still we must not forget that they have a basis of sound sense, and that sudden alterations in the position of the patient's body do often exercise a material influence in favouring the restoration to place of incarcerated portions of bowel. An old man whom I attended several years ago on account of a strangulated scrotal hernia of large size, insisted on my attempting its reduction while he was in a position with the trunk depending, being hung by his knees, which were bent over the rail at the foot of the bed. The plan succeeded admirably, and he assured me that it had often done so before, when he had reduced the rupture himself. My friend Mr. Tyrrell related to me, not long ago,

a case which came under his observation at St. Thomas's, illustrating the usefulness of violent jactitation on the reduction of hernia. A man suffering from strangulated inguinal hernia was seen at his own house at Blackheath by Mr. South, and, attempts at the taxis having failed, Mr. South sent him up to the Hospital, intending to follow and perform the operation. The man was taken in a cart without springs, and on the way the jolting of the vehicle reduced the hernia. Now, although, as remarked, resort to such expedients is altogether unnecessary in the case of hernia, yet in the treatment of internal obstructions we cannot afford to be so independent. The plan which I would advise to be pursued would be as follows:—Let the patient be put under the full influence of chloroform, and then let the abdomen be subjected to careful examination, in order, if possible, to detect the seat of mischief. The rectum should also be examined. The next step should be the passage, with great care, of a pretty firm bougie, or an O'Bierne's tube, in order to ascertain the state of the colon. No information having been obtained, a very copious enema of water should be given, the anus being covered by a cloth and supported by the hand, and the fluid forced in to the utmost point of distension. And now, simultaneously with the withdrawal of the tube and the escape of the water, let the Surgeon, with the flat of one hand on each side the abdomen, press gently but firmly on alternate sides, in such a way as to facilitate the movements of the coils of bowel upon each other. Having done as much of this as may seem advisable, and the water having flowed out, let the patient, by means of a girth fastened to the bed-posts, be raised by the feet until the axis of the trunk is inverted; and while thus placed, let the Surgeon, with both his hands placed on the lower part of the abdomen, press the whole mass of intestines as high up in the abdomen as practicable. In nine cases out of ten, at least, the seat of an internal strangulation is below the level of the umbilicus, and such a method as that adverted to would, it seems to me, be the most likely to liberate it. Of course, during the whole of the time an assistant should carefully watch the effects of the chloroform on the patient's pulse, etc., and guard against the head being allowed to hang down. With ordinary precautions in this respect, I cannot think that the treatment would be attended by any risk worth taking into account. Should no benefit be obtained by the first trial, it might be well to make a second, and to give the injection while the patient's trunk was inverted.

The only case (d), excepting the one given above, in which I have had an opportunity of trying any modification of this plan was that of a little boy, aged 3, whom I saw in May last. He was the son of an innkeeper in Bishopsgate-street, and I had prescribed for him a few months before on account of prolapsus ani. On Thursday, May 8, I was called to him on account of symptoms of internal obstruction. His illness had commenced suddenly on the previous Sunday, with pain in the abdomen. Since then he had had no motion, had been very feverish, and in much pain both night and day. Three doses of jalap and two of castor oil had been given, but all had been rejected. Suspecting the existence of an intussusception, I determined not to delay treatment. We put him soundly to sleep with chloroform, and then pumped up a most copious enema of warm water. He had vomited during the commencement of the inhalation, but when quite unconscious the abdomen became soft and flaccid, and admitted of deep pressure. It was full and tympanitic. I had manipulated gently before the enema, but could detect nothing excepting that there was much gurgling on pressure over the right iliac fossa. The injection was given until the bowel would hold no more, and had perceptibly increased the fulness of the abdomen. I then proceeded to press deeply on each side, more especially on the right where the gurgling had been heard. At first only water returned, but in the course of a few minutes an escape of gas took place, and suddenly a copious motion followed. During the next few days the boy was feverish and out of sorts, but he ultimately got quite

well. I have seen him recently for another complaint, and he has remained quite well as regards the bowels. It should be observed that no blood was ever passed, either with the motion or before, so that an important link in the chain of symptoms denoting intussusception was wanting. The case, too, was not one of the most severe, and the treatment was resorted to in an early stage. One of the greatest recommendations of the plan suggested is, however, that being almost free from risk of doing injury, it may be employed early in the case.

The propriety of giving large enemata in cases of intestinal obstruction has long been a well-established surgical rule, but I feel convinced that much greater advantage will be obtained from it if chloroform be first administered, and if the attempted rectification be conducted somewhat after the method just described. The injection of ice-cold water is an expedient also well worthy of trial if the patient be not sunk so low as to make it dangerous. The patient may be instructed to lay on his stomach for as long period as possible, a position in which it is not at all improbable but that a twist of bowel might rectify itself. It is, of course, only in cases in which peritonitis has not set in that this position could be tolerated. Tobacco enemata are too perilous to be thought of, but should the patient not have been a smoker it might be well worth while to try the effect of inducing, by means of a first pipe, a state of extreme muscular relaxation. In the introduction of the colon tube it is important to bear in mind the hints so well given by its advocate Dr. O'Bierne. The tube should not be too flexible, and should be rounded and bulbous at the end. The curves of the bowel being borne in mind, it may be pushed forward with considerable boldness. Should any obstacle to its further passage be encountered, the surgeon may, whilst holding the tube firmly pressed against it, direct his assistant to inject forcibly a few syringe-fulls of fluid, an expedient which will generally be efficient.

*Under what circumstances is the use of purgatives warrantable?*  
It will be generally admitted that when once the diagnosis of obstruction from mechanical cause has been arrived at, there can be no more excuse for giving violent purgatives than there would be in a case of hernia. There is however a time, in the very beginning of the case, in which the diagnosis may be doubtful, and considering the frequency with which impositions of hardened feces are the cause of such symptoms, probably in most instances in which special indications are absent it may be well to give a single good dose of calomel as a preliminary measure. There is another class of cases in which the use of drastics would certainly be counter-indicated, but in which, perhaps, the employment of minute doses of Epsom salts, with the view of liquifying the motions, might be warrantable. I allude to those of malignant stricture and constipation from large accumulations. It may easily be supposed that solid fecal matter would be arrested by a cancerous stricture which might yet let fluids pass. In cases of retained feces, to combine nux vomica with the laxative would be good practice. In the cases which have resisted all means, and in which the abdominal taxis has been fairly tried and failed, in which the worst stage is rapidly advancing, I presume there can be no difference of opinion, that our sheet anchor is opium, and that it may be given to almost any extent. The patient's vital powers may be yet further husbanded by giving frequent nutrient enemata, and by preventing vomiting by not allowing him to swallow. Ice is an exception, as it rather soothes than irritates the stomach, and in some instances the ice of frozen milk might be used with advantage.

### CANCEROUS INFILTRATION OF THE LYMPHATIC GLANDS AND AREOLAR TISSUE OF THE NECK.

By H. STILWELL, M.D.

W.B., aged 50, has suffered at intervals during the last six years from neuralgia of the right side of the head, for which he has been cupped over the right temple no less than nine times. On seeing him about six weeks ago, he complained of intense pain over the right side of the head, and slight difficulty in swallowing. The lymphatic glands at the angle of the jaw were somewhat enlarged and indurated. During the progress of the case the right side of the neck first became

(d) Since writing this a case has occurred in the practice of my colleague, Mr. Childs, with whom I saw the patient, in which a most happy result ensued on the adoption of the plan advised. The symptoms had existed five days, and the vomiting, although not stercoraceous, had been most urgent. Gastroscopy had been strongly urged by a Physician who saw the case. Chloroform was given, and the abdominal taxis adopted. The man's position was also inverted for lengthened periods at a time (not under chloroform). At length the bowels acted, and recovery at once ensued. Mr. Childs, I believe, intends to publish the case in detail.

the seat of a diffused subcutaneous induration, which gradually extended across the median line towards the left sterno-mastoid muscle; devoid of pain, but attended by increased difficulty in deglutition. This induration became more and more intense, and the integuments, formerly of their natural hue, discoloured.

The patient was gradually sinking from insufficient nourishment; and on the evening of Feb. 21 a messenger came to say that respiration, which had been performed during the last two or three days with some difficulty, was now seriously impaired, and the patient threatened with suffocation. Mr. Maunder accompanied me to see the case, and on arrival we found the patient sitting up in bed breathing with difficulty, and incapable of bending his neck in consequence of the induration of the tissues. Over the right side of the neck and median line the integuments were of a dusky red colour, doughy and quaggy, yielding also an obscure sense of fluctuation. To prevent immediate suffocation, it was thought advisable to incise the integuments, which being done to the extent of one and a-half inch opposite the cricoid cartilage and trachea, a quantity of bloody serum flowed, and the patient breathed freely. On introducing the finger, it passed to the right side of the trachea into a quagmire of degenerate tissues.

Feb. 22nd.—The patient breathes easily.

Feb. 28th.—The patient died to-day from inanition.

*Post-mortem Examination.*—Under pretence of examining the wound in the neck, Mr. Maunder cut down upon the œsophagus, and found it to be the seat of cancerous deposit in the submucous tissue; thus explaining the difficult deglutition. The lymphatic glands beneath either sterno-mastoid muscle were enlarged, indurated, and the seat of malignant deposit, while the areolar tissue of the whole right side of the neck, extending across the median line to the left side, was infiltrated with cancer. On the right side of the trachea the malignant deposit was breaking down.

Uxbridge.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### ST. BARTHOLOMEW'S HOSPITAL.

#### CASE OF CHRONIC HYDROCEPHALUS TREATED BY PUNCTURE—DEATH.

Under the care of Mr. LAWRENCE.

Communicated by Mr. CHIFFERDALE, House-Surgeon.

A delicate, ill-nourished, hydrocephalic child, seven weeks old, was brought on December 29 to the Hospital. The history that the mother gave was as follows:—She stated that the child at birth did not present any unusual appearance, but that about three weeks afterwards, she first observed a swelling at the back of the head, and from that time the head had enlarged with a rapidity quite out of proportion to the growth of the other parts of the body.

Unfortunately there was no opportunity of ascertaining by measurement the exact circumference and breadth of the head previous to the evacuation of the fluid, but as far as one could form an opinion from a hasty examination with the hand, there could not have been a less interval than three inches between the parietal bones, and from the coronal suture to the apex of the occipital was a space of at least seven. There were some slight peculiarities in the shape of the head. It differed in some respects from the ordinary appearances of hydrocephalus. There was a want of symmetry about the head, from the bones not being equally expanded. For instance, there was scarcely any protrusion of the frontal bone, not that marked prominence which is generally seen, and might have been expected in the present case, considering the quantity of fluid evidently contained in the cavity of the cranium. It was evident, however, from the protrusion and downward direction of the eyes, that the orbital plates were depressed. The occipital bone was thrust downwards and backwards, so that it was nearly horizontal in its direction, but this may have been due to the position in which the child

habitually lay, allowing the fluid to gravitate towards the posterior and most dependent part. The same explanation may account for the absence of lateral symmetry, the left parietes projecting more than the right. This, however, did not disappear on the position of the child being changed.

The child lay in its mother's arms in a semi-comatose state, apparently not taking notice of anything passing around, occasionally giving a low moan. The head drooped helplessly on one side, the vertebrae and muscles not being sufficiently strong to maintain it in the erect position. The eyes were prominent, directed downwards, and constantly rolling from side to side; and, to add to the disfigurement, there was divergent strabismus. The pupils were rather dilated. Such had been the state of the child for the last few weeks; but of late the head had enlarged so rapidly, and the little sense or power of perception which the child possessed had become more dim, while at the same time the nutrition of the other parts seemed almost at a stand-still. Under these circumstances, so hazardous to the existence of the child, no other course was open than a resort to the trochar. After some difficulty the scruples of the mother were overcome, and her consent obtained. A very fine trochar and canula were introduced into the coronal suture, about an inch or so from the middle line, in order to avoid the longitudinal sinus, and eight ounces of clear, pale fluid drawn off.

It escaped with a slight saltatory motion, being influenced, I presume, by the movements of the brain, or by the cries that the puncture evoked. The effects of the removal of the pressure were immediate and decided. While the fluid was flowing the child gave a louder cry than it had ever before uttered, and showed other signs of being more lively. The eyes receded somewhat from their former prominent position, and assumed a more natural direction; the rolling ceased; the strabismus became less marked. The bones of the cranium collapsed, their serrated margins being distinctly visible. More might have been drawn off, but it was not thought advisable to do so. The child bore the operation remarkably well, no convulsions ensuing. Strips of plaster were then applied in a circular manner around the head, to compensate for the pressure of the withdrawn fluid.

The child was brought to the Hospital four days afterwards. The mother stated that the child had appeared much relieved, and had been more cheerful and lively for the first two days, but on the third it had been very restless and feverish, and from that time had relapsed into the same drowsy condition. The head, on the removal of the strapping, appeared very tense, and to have acquired almost the same dimensions. The surface of the head was hot. Mr. Lawrence repeated the puncture, but in a different situation, selecting the posterior part, as the fluid gravitated in that direction. Ten ounces were let out. A little hæmorrhage followed the perforation, and the child became rather blanched. I thought I observed a few slight, transient, convulsive movements of the face, and a clenching of the hands. No compression was employed this time, merely cold applied, and hyd. c. cretâ, gr. iij. ordered to be taken every night. The child was again brought on Tuesday last, four days after the second puncture. The head had not enlarged to the same extent as before. The child had not been so drowsy, but, on the contrary, more restless. Its appearance was much more animated. Dose of hyd. c. cretâ increased.

Another ten days elapsed before the child was again brought to the Hospital. The mother stated that during that time the child had continued to improve in health, and had shown more animation. The head continued about the same size as before. Not having seen or heard of the child for more than three weeks, I proceeded to inquire at the mother's residence, but unfortunately the family had left a few days before, and the landlord was unable to inform me where they had moved to. I learnt, however, from him that the baby had died about ten days back, apparently from in-nutrition; that the head had not, in his opinion, increased in size, and that it had had no convulsions.

### HOSPITAL NOTES.

#### UNUSUAL POSITION OF THE RIGHT KIDNEY.

Mr. Maunder, Demonstrator at Guy's Hospital, informs us that there is at present in the dissecting-room of Guy's Hospital a subject in which the right kidney, instead of occupying its usual position, is placed over the fifth lumbar

vertebra and sacral promontory. The organ is somewhat flattened against the vertebral column, its convex border looking backwards and upwards, its hilum directed downwards and forwards. The corresponding supra-renal capsule is *in situ* below the liver. This abnormality is worthy of note, inasmuch as the knowledge of the fact that healthy organs are occasionally curiously misplaced, will add one to the many fallacies connected with the diagnosis of abdominal tumours. Doubtless, in this case, had the subject been thin, the displaced kidney might have been felt during life.

#### VALERIANATE OF AMMONIA SUCCESSFULLY USED IN NEURALGIA.

The efficiency of the valerianate of ammonia as a remedy in the cure of neuralgia has been frequently proved in a number of patients admitted at the Royal Free Hospital, under the care of Dr. O'Connor. The following case, of twenty-one years' almost constant suffering, is an excellent illustration of the success attending its use:—E. W., a woman of colour, 38 years of age, single, by occupation a dress-maker, was admitted an out-patient, under the care of Dr. O'Connor, on the 24th of February last. She stated that since the age of 17 she had been a constant sufferer from a neuralgic affection of the left side of the head, face, and neck, from which she was seldom free for twelve hours at a time, and her sufferings were often so great as to make life feel a burden to her. She had been under the care of many medical men, and had, without benefit, obtained advice at nearly all the medical institutions of the metropolis. Large doses of quinine and iron, as well as the internal and external use of belladonna and other anodynes, with hydrocyanic acid, were had recourse to without any good result. When the patient presented herself at the Royal Free Hospital she was suffering excruciating pain over the whole of the left cheek, there was dropping of the left eyelid, otherwise she was in good health, and from the age of 14 had regularly menstruated; there was no evidence of deranged stomach, and she had never suffered from any other illness. Five teeth had been from time to time removed, without any alleviation of her sufferings. On examination of the mouth, Dr. O'Connor noticed three stumps of decayed teeth, which he thought might in some manner promote the sufferings of the woman. Those he ordered to be removed, which was done by Mr. Robinson, the dentist to the Hospital. She was ordered a dose of purgative medicine, with anodyne fomentations. On the 27th she again presented herself, when she stated that, instead of obtaining relief, she was in constant agony since her last visit, although she had complied with the directions. Her bowels had been freely relieved. Dr. O'Connor now ordered one drachm of the solution of the valerianate of ammonia in an ounce of infusion of colomaba, to be taken three times a-day. At her next visit to the Hospital, March 6, she described her feeling to be as one "almost in heaven" since the previous Monday, so great was the relief afforded. The dose of the valerianate of ammonia was now increased to one drachm and a half three times a-day; and at her next visit, on the 10th of March, the patient stated that she was cured, having been completely free from pain since she last appeared at the Hospital, and able to pursue her occupation with comfort.

#### THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

#### STATISTICAL REPORT OF THE PRINCIPAL OPERATIONS PERFORMED DURING THE YEAR 1857.

THE subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire

General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

#### AMPUTATIONS.

*Of the Thigh.*—Case 1.—The Cheltenham: Mr. Eves.—A woman, aged 46, for fourteen years the subject of elephantiasis of the foot and leg, with deep ulceration. Amputation. Recovery. Case 2.—The Liverpool Royal: Mr. Bickersteth.—A delicate girl, aged 15. Amputation through the thigh on account of medullary cancer of the lower third of the femur, of six months' duration. The growth had a strong pulsation, and was increasing rapidly with much pain. Amputation. Recovery. Case 3.—The Sussex County.—A delicate boy, aged 7. Amputation on account of diseased knee-joint. Recovery. Case 4.—The North Stafford: Mr. Ball.—Amputation just above the knee, on account of chronic disease of the synovial membrane. The disease was of six years' duration. Recovery. Case 5.—The York: Mr. Husband.—A delicate boy, aged 11. Amputation above the knee on account of extensive necrosis of the tibia. Recovery. Case 6.—The York: Mr. Hey.—A stout girl, aged 9. Amputation on account of strumous disease of the knee-joint. Recovery. Case 7.—Addenbrooke's, Cambridge: Mr. Hammond.—A scrofulous man, aged 23, the subject of diseased knee-joint for seven years. Amputation. Recovery. Case 8.—The Glasgow Infirmary.—A woman, aged 32, the subject of old-standing disease of the knee. Recovery. Case 9.—A man, aged 47, the subject of diseased knee for six years. Recovery. Case 10.—A girl, aged 9. Secondary amputation after compound fracture. Recovery. Case 11.—The North Staffordshire: Mr. Ball.—Amputation on account of diseased knee-joint. Recovery. Case 12.—Mr. Jackson.—A man, aged 35. Amputation on account of strumous disease of the knee-joint. Recovery. Case 13.—The Leeds: Mr. Teale.—A strumous girl, aged 20, the subject of chronic disease of the knee-joint. Amputation. Recovery. Case 14.—The North Staffordshire: Mr. Turner.—A girl, aged 16, in very feeble health. Amputation of the thigh on account of malignant disease of the femur. Recovery. Case 15.—Addenbrooke's, Cambridge: Mr. Hammond.—A man, aged 41, of rheumatic diathesis, the subject of chronic disease of the knee. Amputation. Recovery. Case 16.—The Dundee: Mr. Crockett.—A man, aged 25, the subject of diseased knee-joint of a year's standing. Amputation. Recovery. Case 17.—The Dorset County: Mr. Curme.—A lad, aged 18, who had been long under treatment for disease of the knee-joint. Amputation. Recovery. Case 18.—The Dorset: Mr. Curme.—A girl, aged 12, for two years the subject of diseased knee-joint. Amputation. Recovery. Case 19.—The Bristol General: Mr. Coe.—A boy, aged 4, whose knee-joint had been excised six months previously. Union had not followed, and disease still existed about the bones. Amputation. Recovery. Case 20.—The Staffordshire General: Dr. Masfen.—A man, aged 30, in fair health. Amputation on account of diseased knee-joint. Recovery. Case 21.—The Staffordshire General: Mr. Waddell.—A woman, aged 51, the subject of diseased knee-joint. Amputation. Recovery. Case 22.—The Leicester: Mr. Paget.—A girl, aged 16, in fair health. Amputation on account of diseased knee-joint. Recovery. Case 23.—The Leicester: Mr. Paget.—A man, aged 25, in fair health. Amputation. Recovery. Case 24.—The Leicester: Mr. Benfield. A strumous girl, aged 16, for three years the subject of diseased knee-joint. She had been an inmate of the Infirmary for two years. Excision of the joint was proposed, but during its performance such extensive disease of the tibia was found to exist, that amputation had to be resorted to. Recovery. Case 25.—The Leicester: Mr. Benfield.—A healthy labourer, aged 36, was admitted on account of a compound fracture of the femur through its condyles. An attempt was made to save the limb, but gangrene having supervened, and extended as high as the knee, it was found necessary to amputate. On examining the limb, an extensive longitudinal fracture of the femur was found, and there had been large effusion of blood into the knee-joint. Recovery. Case 26.—The Bradford: Mr. Meade.—A man, aged 33, for three years the subject of diseased knee-joint. Amputation. Recovery. Case 27.—The Bradford: Mr. Poppleton.—A man, aged 23, for nine months the subject of diseased knee-joint. Amputation. Recovery. Case 28.—The Bradford: Mr. Meade.—A girl, aged 11, the subject of ankylosis of the knee. Amputation. Recovery. Case 29.—The Sheffield:

Mr. Barber.—A woman, aged 20, the subject of diseased knee-joint from childhood. Amputation. Recovery. *Case 30.*—The Hull: Dr. Lunn.—A lad, aged 17, for fifteen months the subject of diseased knee-joint. Amputation. Recovery. *Case 31.*—The Hull: Dr. Lunn.—A lad, aged 13, the subject of diseased knee-joint. Amputation. Recovery. *Case 32.*—The Sussex County: Mr. Blaker.—A man, aged 20. Amputation on account of diseased knee-joint of eighteen months' duration. Recovery. *Case 33.*—The Sussex County: Mr. Blaker.—A boy, aged 13. Amputation through the thigh on account of diseased knee-joint of nine years' duration. Recovery. *Case 34.*—The Leeds: Mr. Hey.—A girl, aged 12, whose knee-joint had been excised twelve months before. No bony union had resulted, and part of the wound was still open. Amputation. Recovery. *Case 35.*—The Leeds: Mr. Teale.—A man, aged 32, for seven years the subject of diseased knee-joint. Amputation. Recovery. *Case 36.*—The York: Mr. Husband.—A miner, aged 42, of feeble constitution, was admitted with an ununited fracture of the tibia and fibula, six months after the accident. Excision of the extremities of the tibia was performed, and he did well for some time. Eventually, profuse suppuration, and consequent hectic, necessitated amputation above the knee. Recovered. *Case 37.*—Addenbrooke's, Cambridge: Mr. Humphry.—A woman, aged 22. Amputation on account of necrosis of the femur. Recovery. A large sequestrum had been removed, but her health was failing. *Case 38.*—The North Stafford: Mr. Ball.—A feeble man, aged 28, the subject of albuminuria. Amputation on account of diseased knee-joint. Recovery. *Case 39.*—The Dundee: Dr. Crockatt.—A phthisical lad, aged 17. Amputation for diseased knee-joint. Recovery. *Case 40.*—The Glasgow Royal.—A girl, aged 17. Amputation for diseased knee-joint. Recovery. *Case 41.*—The Glasgow Royal.—A lad, aged 18. Amputation for diseased knee-joint. Recovery. *Case 42.*—The Glasgow Royal.—A girl, aged 14. Amputation on account of disease of the tibia, involving also the knee-joint. Recovery. *Case 43.*—The Glasgow Royal. A girl, aged 7, the subject of strumous disease of the knee-joint of a year's standing. Recovery. *Case 44.*—The Liverpool Southern: Dr. Nottingham.—A boy, aged 14, admitted with a compound fracture of the femur. Primary amputation was refused. Secondary amputation on the eleventh day. Recovery. *Case 45.*—The Liverpool Southern: Mr. Hamilton.—A man, aged 35, admitted on account of a compound fracture of the leg. Secondary amputation, on account of gangrene, on the sixth day. Under treatment. *Case 46.*—The Gloucester: Mr. Wood.—A man, aged 21, much reduced by disease of the knee consequent on a fall. Amputation. Recovery. *Case 47.*—The Royal Berkshire: Mr. Moxhay.—A girl, the subject of disease of the knee-joint, which had reduced her from previous good health to the most extreme debility. Amputation. Recovery. *Case 48.*—The West Norfolk: Dr. Cotton.—A healthy man, aged 46, was admitted with compound fracture of the leg. Gangrene supervened, and secondary amputation was performed on the twelfth day. Recovered. *Case 49.*—The Dundee: Dr. Crockatt.—A feeble girl, aged 18, the subject of strumous disease of the knee-joint. Recovery. *Case 50.*—The Hull: Dr. Lunn.—An intemperate man, aged 53, in tolerable health, was admitted with a most severe compound dislocation of the knee-joint. Primary amputation three hours after the accident. He never rallied, but gradually sank, and died on the fourth day. *Case 51.*—The Hull: Mr. Huntingdon.—A man, aged 22, in fair health. Amputation of the thigh, on account of medullary disease of the lower part of the femur. He did well until about the end of the third week, when difficulty of breathing came on. He died on the 33rd day. The autopsy showed both lungs infiltrated with cancer. *Case 52.*—The Bradford: Mr. Meade.—A girl, aged 19, the subject of diseased knee-joint. Amputation. Death soon after the operation. *Case 53.*—The Sheffield: Mr. Gregory.—A woman, aged 38. Amputation, on account of strumous disease of the knee. The stump was nearly healed, when gastritic symptoms supervened. She died hectic in the sixth week. *Case 54.*—The Leicester: Mr. Macaulay.—A man, aged 32. In feeble health. Amputation, on account of medullary cancer about the knee-joint. Very profuse hæmorrhage occurred during the operation, and he was with difficulty rallied by the copious use of stimulants. He subsequently sank, and death occurred on the fourteenth day. No autopsy. *Case 55.*—The Leicester: Mr. Benfield.—A girl, aged 16, in fair health. The subject of chronic

disease of the knee-joint. Amputation on May 21. She did well until within three days of death, when an attack of faintness occurred, followed by a succession of rigors. The rigors continued, and death occurred on June 3. No autopsy was allowed, but the cause of death was probably pyæmia. *Case 56.*—The Dorset County: Mr. Curme. A navvy, aged 28, admitted with compound comminuted fracture of the leg. Secondary amputation on the eleventh day, on account of mortification. On the sixteenth day after the operation, all the ligatures having come away nearly a week before, a frightful attack of hæmorrhage occurred (during the night), from the effects of which he sank next day. On examination of the limb, it appeared that the bleeding had been from the femoral trunk. *Case 57.*—The Dundee: Dr. Crockatt.—A lad, aged 16. Admitted with a compound fracture of the thigh from a railway accident. Primary amputation twenty-four hours afterwards. Death from shock within four hours. *Case 58.*—The Leeds: Mr. Smith.—A healthy boy, aged 11, the subject of severe compound fractures of both legs. Primary amputation through the thigh on the left side. Death from pyæmia in the sixth week. *Case 59.*—The Glasgow.—A man, aged 24. Primary amputation, on account of an extensive burn of the thigh and leg. Death from phlebitis on the ninth day. *Case 60.*—The Glasgow.—An intemperate man, aged 57. Primary amputation, on account of compound fracture. Death from exhaustion. *Case 61.*—The Glasgow.—A man, aged 37. Secondary amputation, on account of gangrene following compound fracture. Death from phlebitis on the fifteenth day. *Case 62.*—The Glasgow.—A man, aged 40, the subject of diseased knee-joint following an injury. Amputation. Death from phlebitis on the eighth day. *Case 63.*—The West Norfolk: Mr. Sayle. Primary amputation, on account of compound fracture of the left leg near the knee-joint. Death from tetanus. *Case 64.*—The Derby: Mr. Giaborn.—A girl, aged 14, in bad health, the subject of malignant disease of the knee-joint, which was ulcerated, and liable to bleed. The disease had existed four months. Amputation. The stump healed, but death from diarrhoea and exhaustion followed in the 6th week. *Case 65.*—The Queen's (Birmingham).—A lad, aged 10, in feeble health. Amputation on account of old standing disease of the knee-joint. Considerable hæmorrhage at the time of the operation. Death from exhaustion the same evening. *Case 66.*—The York: Mr. Husband.—A pale, unhealthy man, aged 23. Amputation of the thigh, on account of medullary cancer about the knee. He did well for about a week, and then sank from pyæmia. *Case 67.*—The York: Mr. Hey.—A delicate man, aged 25, was admitted, having had the right leg and foot severely crushed and the left foot smashed by a railway accident. Part of the left foot was removed by a primary amputation, and the stump did well. Secondary amputation through the right thigh was subsequently performed, on account of exhaustion from the profuse suppuration. Death from pyæmia. *Case 68.*—The York: Mr. Hey.—A feeble man, aged 65. Amputation on account of extensive disease of the tibia, extending into the knee-joint. Death from exhaustion. *Case 69.*—The Hull: Mr. Craven, jun.—A lad, aged 16, admitted for a severe gun-shot wound of the calf. Primary amputation. Death on the sixth day. *Case 70.*—The Royal Berkshire: Mr. May.—A thin, pale lad, the subject of encephaloid cancer of the fibula of five months' standing. The tumour was very large, measuring twenty-one inches in diameter. Amputation on June 13. On June 27 chest symptoms supervened, and he died on July 3. At the autopsy the lungs were found infiltrated with cancer. *Case 71.*—The Gloucester: Mr. Wood.—A lad, aged 11, in good general health, the subject of ankylosis after disease of the knee-joint. Amputation. On the eighth day erysipelas attacked the stump; phlebotic symptoms supervened, and death took place on the eighteenth day. *Case 72.*—The Hull: Mr. Huntingdon.—A man, aged 25, was admitted with a compound fracture of the thigh, together with other severe injuries. Primary amputation. Death from collapse eight hours after the operation. *Case 73.*—The Hull: Mr. Huntingdon.—A seaman, in miserable health, aged 60, was admitted with extensive sloughing of the leg, the result of neglected phlegmonous erysipelas. Amputation. Death on the seventh day, from exhaustion. *Case 74.*—The North Staffordshire: Mr. Turner.—A man, aged 48, the subject of diseased knee-joint. Amputation. Death. *Case 75.*—The Liverpool Southern: Mr. Nottingham.—A man, aged 61.

Amputation for disease of the head of the tibia. Death from pyæmia on the sixth day.

(To be continued.)

## Medical Times & Gazette.

SATURDAY, APRIL 3.

### POISONING IN OUR BARRACKS.

It has become generally known, since the publication of the Report of the Royal Commissioners, that of all the unhealthy occupations in the kingdom the occupation of a soldier at home in time of peace is almost the most unhealthy, and that our soldiers die at twice the rate they would die if the army at home were as healthy as our general population. But it is not generally known, and the public may at first be startled by the assertion, that a large proportion of this unnecessary mortality is the result of Poisoning. Yet this is the truth; and the poison is no subtle invention of an enemy, none of those compounds of cacodyl which were to be employed in shells to destroy the Russians in Sebastopol; no new form of liquid gun cotton called glonéine, which in the fiftieth dilution may produce in imaginative people the most wonderful effects; but a gas so deadly that it can destroy every man by suffocation sleeping in a room filled with it, and by a process of slow poisoning when it is administered in a dilute form. But, more wonderful than all, this gas our soldiers manufacture for themselves, and our barracks are so constructed, that, instead of being carefully swept away, it is carefully bottled up, and our soldiers are more or less slowly poisoned by our old friend, CARBONIC ACID.

The readers of the *Medical Times and Gazette* need not be told this. The youngest of them knows well how in the process of respiration man exhales carbonic acid, but it may be as well to remind them of a few illustrations by which this fact may be impressed on the public mind, and a great deal of the nonsense one reads and hears about barrack accommodation may be put a stop to.

Let Lord Panmure go down in the diving-bell at the Polytechnic. So long as Mr. Pepper's men keep a good stream of air passing through the bell, his Lordship may remain in tolerable comfort at the bottom of the well. He gets as much oxygen as he wants, and the carbonic acid he forms is blown away. But make St. Paul's or any other large cathedral as air-tight as the diving-bell; shut up his Lordship in it with a good supply of food and drink, and if the capacity of his lungs be given, and the number of respirations in the minute known, with the cubic space of the cathedral, it becomes a matter of very simple arithmetic to calculate the exact time when the noble Secretary at War would die poisoned by the carbonic acid he has exhaled—in plain terms, suffocated.

But if instead of one man in a large cathedral we take a hundred men in a confined space—What then? Why the old story of the Blackhole at Calcutta in 1756. A prison 18 feet square, not an air-tight chamber but closed, 146 Eng-

lishmen confined in it at night, and only 23 found alive in the morning. The same old story of the *City of Londonderry* steamer in 1840, encountering bad weather on her passage from Ireland to Liverpool, the captain battenning down the steerage passengers in the fore part of the ship, and poisoning 73 of his fellow-creatures. So in 1833 two young men on board the *Magnus Troil* in Leith harbour went to bed in the cabin, and shut the door so closely that one was found dead and the other dying in the morning. So in 1840, two strong young men were poisoned under precisely similar circumstances, in the cabin of the *Mary Hardie* lying at Greenock. And so we might go on with instance after instance of poisoning by carbonic acid, the rapidity of the poisoning varying with the size of the chamber, the number of people it contained, and the accuracy with which it was closed; all proving, what our readers very well know, that a person breathing in an air-tight chamber will just as certainly poison himself with his own breath as if charcoal were burnt in the place, or it was filled with carbonic acid from a retort.

But sudden death—rapid poisoning—by carbonic acid is the exception. Slow poisoning is the rule. Man is not very often exposed to the undiluted poison he himself forms. Notwithstanding the rapid progress of art and science, however well our carpenters and glaziers may work, however skilfully our architects may form their plans, it is not very often that our rooms are so constructed as to be absolutely air-tight. Currents of atmospheric air will come in through crevices of doorways and window-sashes, and some of the poisonous gas will go out, in spite of architect, carpenter, and glazier. And so we come to observe the effects of the diluted poison, and watch the process of slow poisoning or chronic suffocation.

Now this process, the effects of which have been so lately exemplified in the case of the British soldier, has been studied before in the case of certain monkeys at the Zoological Gardens, as we may see by the following extract from a little work by Mr. Spencer Wells, published in 1861, on the Preservation of the health of seamen:—

"It is not very long since a new house was erected under the direction of an eminent architect to accommodate the monkeys in the Zoological Gardens of the Regent's-park, and this dwelling was to resemble as nearly as possible an English gentleman's drawing-room. Two ordinary drawing-room grates were put in, with low chimney openings as close to the floor as possible, and the windows and other openings above were made perfectly close. Some warm air was also admitted through openings in the floor. All the openings for winter ventilation were made close to the floor, under the erroneous belief that the gas produced by the respiration of the animals, being heavier than the other air of the room, would fall and escape below. The architect forgot that it issued warm, and therefore light from the animals, and that when cold it would become diffused and mix with the other air. Sixty healthy monkeys that had been several years in England were put into this room. In one month fifty of them were dead, and the other ten dying. The animals were all poisoned by their own breath. They were living in an extinguisher. All the hot breath and impure exhalations of the monkeys were collected in the upper part of the room, could not escape, and poisoned them. As soon as some openings in the upper part of the room, which were intended only for summer ventilation—as if the monkeys could live without pure air in winter—were unclosed, the room became perfectly habitable, the ten sick monkeys recovered, and those since placed in it have remained perfectly healthy. It is curious that all the monkeys that died are said to have died with tubercles in the lungs—true consumption—the most prevalent disease of this climate, which is developed, I am persuaded, in numberless instances in our population in the same manner, but less suddenly, as among these monkeys. Our schools and nurseries are not quite so close as this monkey-house, but there is no very great difference in many. The windows are not opened for fear of draughts of cold air, there is only one door and that is seldom opened, and the chimney opening is not more than three or four feet from the floor. Even that is often closed.

The effects are bad enough in large rooms inhabited by few people, but when rooms are small or crowded, the magnitude of the evil can scarcely be appreciated. In a ship, when the ports and hatches are closed, the people are exactly in the same situation as the monkeys. They poison themselves with their own breath, and generally much quicker than the monkeys did, because they are more crowded, and the pure air is more effectually excluded."

Now, let us apply all this to our barracks. Let us remember, first, that a healthy man requires four cubic feet per minute of pure air to ensure the changes which should take place in his blood during respiration, and to remove and sufficiently dilute the poisonous gas he exhales. Secondly,—that this poison, as it issues *warm* from the body, is specifically *lighter* than air, and, finding no opening for escape higher than the fireplace, it rises and fills all the upper part of the room. Thirdly,—that currents of pure air passing from beneath doorways to the fireplace carry very little of the poison with them, the air above the level of the outlet being very little affected, as the impure is lighter than the pure air. Fourthly,—that adults breathe in the upper part of rooms. Their heads being above the level of the pure air, they are breathing a varying amount of poison. We may take another illustration from the work just quoted:—"If a bird be suspended in a cage from the top of a four-post bedstead in which two persons are sleeping, and the curtains are drawn closely together, the bird will certainly be found dead in the morning, poisoned by the breath of the sleepers, who, if they were at the same level with the bird, would just as certainly poison themselves." Remembering all this, anyone may see what nonsense it is to talk about the mere cubic space of our barracks as a matter of great importance in relation to the health of the men. It is not the size of a room in which men sleep, but the purity of the air in it, we should consider—the supply of fresh air, and the outlets for the poisonous gas. It is the "want of pure air," not "want of space," which kills our soldiers in barracks. A man might live a long time in a diving-bell well supplied with pure air, while he would soon be poisoned in a cathedral hermetically sealed. Of course he has a better chance of getting pure air in a large room than in a small one; but it is perfectly possible and easy to keep a small room sufficiently and abundantly supplied with pure air. And the practical bearing of this is most important. A few nights ago, in the House of Lords, Lord Panmure said:—

"In many places it is utterly impossible to provide those sanitary improvements for which the public now so loudly call. If the Government are to be enabled to carry out in barracks to its full extent the sanitary system which is advocated by the commissioners, I warn your Lordships that it will require a very large sum of money indeed. I am quite ready to take upon myself my full share of blame—if blame there be—for not having asked from Parliament a large sum to be applied in that direction; and I shall throw no blame whatever upon the present Government if they should find it as difficult as I did to meet the public expectations with regard to the improvements in barracks, which are now, I think, raised to a very high and somewhat unnecessary pitch."

This is all a mistake. If it be insisted that instead of 600 cubic feet for each man in a barrack 1200 feet must be given for the future, of course all the expenditure on the building and repairs of barracks must be doubled. But if, as we contend, it should be simply insisted on that every man in barrack shall be supplied with four cubic feet per minute of pure air—(or of air as pure as can be obtained around his barrack)—then this may be done immediately at a small expense with mathematical accuracy and absolute certainty day and night. We do not wish to specify any special plan by which this may be done—whether by Arnott's pumps, which have worked for years past at Brompton, York, and other Civil Hospitals, or by Reid's tubes, or by syphon or suction—but we must endeavour to impress upon our readers, and through them upon the public, the conviction that it is an insult to the mechanical

science which can drive a ship across the Atlantic in a fixed and definite time in the face of opposing winds and currents,—which can supply every gas-burner in the kingdom with a fixed and definite quantity of carburetted hydrogen,—to suppose that it cannot cheaply and constantly supply every British soldier with four cubic feet per minute of the air around us. Let this be done, and we shall have no more twaddle in the House of Lords about "want of space," or "expense," and one of the most efficient but easily preventible causes of the mortality of the Army will be removed—**POISONING BY CARBONIC ACID.**

## THE WEEK.

Mr. Cowper's Medical Bill has undergone some slight modifications this week, but we have only received the corrected proof so shortly before going to press that we must delay the comparative summary of this Bill and Lord Elcho's until next week. This delay, however, is of little consequence, as there is scarcely any probability of either Bill passing if both are pushed forward; especially as Mr. Headlam, supported by the Colleges, is to bring in his Bill of last session. Any one of the three parties supporting either of the three Bills has quite sufficient influence to prevent a rival Bill from passing, while unable to get either forced through an indifferent Parliament in the face of Professional opposition.

It gives us much pleasure to state that one of the highest and just now the most important diplomatic offices in the gift of her Majesty's government has been conferred upon the son of a distinguished member of the Medical Profession. The present Envoy Extraordinary and Minister Plenipotentiary from the Court at St. James's to the King of Hanover, Sir John Crampton, K.C.B., eldest son of Sir Philip Crampton, Bart., of Dublin, has been appointed Envoy Extraordinary and Minister Plenipotentiary to the Court at St. Petersburg. The elevation of the son to so important a post must be a very great gratification to the father, and we are quite sure that the whole Profession will join us in sincere congratulations.

A long correspondence has been laid before us, between the Sardinian Government, Lords Clarendon and Malmesbury, and Dr. Vaughan Hughes, with a memorial to the Foreign Secretary signed by 158 Medical men, the subject being one of considerable interest to Medical men who may wish to accept foreign decorations. It appears that Dr. V. Hughes was an Acting Staff-Surgeon in the Crimea, and was appointed by Lord Raglan and Sir John Hall to attend on the Sardinians; that he did attend entirely to them for some time, and that while in close attendance upon them he was attacked with cholera, which placed his life in danger, and ultimately led to his being invalided. The Sardinian Government expressed a wish to give a "mark of satisfaction certainly merited," if Dr. Hughes could obtain the consent of our Government; but both Lord Clarendon and Lord Malmesbury agree that the permission cannot be granted "consistently with the established regulations respecting foreign orders." The sooner the established regulations are amended the better. It really seems an absurd piece of red-tapism to refuse to allow a foreign Government to reward a British subject for services the said Government believe to deserve reward.

Mr. Lawrence has received the appointment of Serjeant-Surgeon to the Queen, vacant by the death of Mr. Travers. Mr. Lawrence's claim to the Serjeant-Surgeoncy was indis-

putable. Mr. Travers was also Surgeon in Ordinary to Prince Albert, and Mr. Lawrence's promotion has made a vacancy for a Surgeon Extraordinary to the Queen. Rumour of course is busy as to the two new Court Surgeons; but, as the names have not been published, we can only express the conviction that merit and not age, ability not favour, are the surest steps towards professional advancement at Court with Her Majesty's present advisers.

We have just received a report of the Special General Meeting of the Odontological Society, held on the 19th inst., containing the correspondence between the Society and the College of Surgeons on the proposed examination in Dental Surgery and the new diploma to Surgeon-Dentists, and an account of the contemplated amalgamation with the College of Dentists. The negotiation with the College of Surgeons is at a stand-still pending the Medical Reform debates in the House of Commons, as a new clause would be required in the Charter of the College; and the projected amalgamation was not arrived at, owing to what appears to be a very ill-judged opposition on the part of the College of Dentists. The Society accordingly have resolved to form a school "for teaching those branches of science appertaining peculiarly to the practice of Dentistry, which are not taught in the existing Medical Schools; and that the Council be requested to draw out the plan of such a School, and be empowered to open it as soon as circumstances permit." And further, "that, in the event of the College of Surgeons being unable ultimately to accede to the propositions contained in the memorials that have been presented to it from the Council of this Society, it would be desirable that the members of the Dental Profession should unite, and endeavour to obtain from the Crown a Charter, or from the Legislature a Bill of Incorporation, for an independent Institution, or College, to regulate the education of future members of the Profession, institute examinations, and grant diplomas of professional qualification." So stands this question until the more general one of Medical Reform is settled.

The state of education in the western districts of England does not appear to be very creditable to the nation. Sarah Palmer, a married woman, after her confinement found herself in a low state of mind, and consulted a certain Esther Peadon, and asked if she could cure her. Esther said she could, and ordered Palmer's finger and toe-nails to be cut, and her hair to be cut off, and she gave her some medicines, which she told her would make her very ill. She said she must not send for a medical man. The finger and toe-nails were ordered to be put into paper, and then put into the neck of a bottle until they perished. Esther asked Mrs. Palmer how much she could afford to pay for medicines at that time. Mrs. Palmer told her she could afford to give 4s., and it was then that the prisoner made up some medicine for her. She became almost out of her mind shortly after taking the medicine. Mrs. Palmer afterwards sent for her husband and complained of her state, and she soon afterwards died—on the 1st of January. The surgeon who made a *post-mortem* examination said in his opinion "she died from an acronarcotic poison, similar to mandrake." The contents of the stomach were afterwards conveyed to Mr. Herapath, the chemist of Bristol. There were some medicines left in the bottles, and those also were sent to Mr. Herapath. Esther was tried at Taunton for manslaughter, before Mr. Justice Crowder, who said that there was no proof that the bottles had been given by the prisoner, nor was there proof that the medicines they contained had been furnished by the prisoner. The jury then Acquitted the prisoner. His Lordship gave the prisoner a caution to take care how she again gave persons medicines; and she is

again at liberty to sell her filthy charms and poisonous herbs to all who are ignorant enough to prefer them to the assistance of gentlemen of education and experience.

## REVIEWS.

*On Malformations, &c. of the Human Heart; with Original Cases.* By THOMAS B. PEACOCK, M.D., Assistant Physician to St. Thomas's Hospital. Pp. 143. London: 1858.

It is well known that Dr. Peacock has devoted great attention to the morbid and abnormal conditions of the heart. In this very useful monograph, he has collected together and classified some of the more extraordinary deviations from healthy structure presented by that organ. Some years ago, Dr. Peacock delivered a series of lectures on Malformations of the Heart to the students of St. Thomas's Hospital, and these lectures were subsequently published in this Journal. The substance of these lectures, amplified by greater experience, and the addition of cases contributed from time to time to different Medical Societies and journals, is contained in the volume now before us. Besides the personal experience derived from his own cases, Dr. Peacock has largely availed himself of all the existing literature on this interesting subject. There are eight plates, the first of which illustrates the seat and form of apertures in the septum of the ventricles; the second shows two cases of obstruction at the orifice of the pulmonary artery, one of the cases showing moreover a defect in the septum of the ventricles; the third exhibits a case of obstruction at the orifice of the pulmonary artery and an open foramen ovale; the fourth plate shows obstruction and obliteration of the orifice of the pulmonary artery; in the fifth are cases of open ductus arteriosus and supernumerary septum in the right ventricle; the sixth delineates a supernumerary septum in the right ventricle, and an open foramen ovale; the seventh plate contains four cases of defect in the number of the semilunar valves, and in plate eight there are four cases in which the number of the same valves was in excess.

In the body of the work, the misplacements of the heart are considered in the following order:—I. Congenital Misplacements of the Heart. II. Deficiency of the Pericardium. III. Malformations of the Heart, including: 1st. Malformations dependent on arrest of development at an early period of fetal life; 2nd. Malformations preventing the changes which should ensue after birth; and 3rd. Malformations which do not interfere with the functions of the heart, but may lay the foundations of disease in after life. IV. Malformations consisting in the irregular development of the primary vessels; and V. The mode of formation, the symptoms and effects, the diagnosis and medical management of cases of malformation.

Where the subjects of description are so numerous, and where almost every case described is a history in itself, it is impossible to offer anything like an analysis; and we must content ourselves with observing that the volume before us is a remarkable instance of Dr. Peacock's industry and research. He has himself investigated a great number of the deviations from normal structure presented by the heart, as the members of the Pathological Society are well aware, and as the records of that Society abundantly testify; and he has now collected together the results of his own observation, compared with the written descriptions given by other observers, both British and foreign, and has condensed and classified them in such a manner as must render his work most acceptable and useful to the Profession.

*On the Mechanical Appliances necessary for the Treatment of Deformities.* By HENRY HEATHER BIGG. Pp. 225. London: 1858.

Mr. Heather Bigg, the well-known and ingenious anatomical mechanist, has here given us a work describing the artificial contrivances suitable for the deformities of the lower limbs. Some of them are applicable in cases where tenotomy cannot be performed; others are employed as adjuncts to that operation; and all are more or less available in some of the distortions to which the leg and foot are liable. The chief deformities described are those of the toes, the different varieties of club-foot, the curved tibia, genu valgum, contracted knee, and

contracted hip-joint; and for all these the forms of apparatus invented from time to time, and now in use among Surgeons, are described and figured. Mr. Bigg is evidently one who desires to exalt his art, and he considers that the surgical mechanist should be a scientific and well-educated person, in order to carry on his business with success. The failure of many former efforts to relieve deformities is attributed by him to the fact, that the mechanists were too often mere "instrument-makers," and were not well acquainted with the mechanical principles on which the human body is constructed; whereas a competent professor of the art should be tolerably well instructed in osteology and myology, both by reading and by witnessing dissections, in order to render intelligent assistance to the Surgeon in carrying out his suggestions. Mr. Bigg himself appears to be well acquainted with the anatomy of the bones and muscles connected with the deformities he describes, and his descriptions therefore of the construction and uses of the various apparatus employed deserve and will command attention. His book must prove of very great value to those practitioners who wish to treat cases of deformity brought under their care without consulting any of the gentlemen who have devoted special attention to Orthopedic Surgery, for there can be no doubt that the great difficulty Medical men have to contend with in such cases is the want of the exact instrument required to carry their wishes into effect, and this want will not be felt by those who possess Mr. Bigg's very useful little work.

*On Pepsine.* By M. BOUDAULT. Translated by W. S. SQUIRE, Ph. D. F.R.C.S. Second Edition. Pp. 32. London: 1858.

Those who wish to know all about pepsine had better expend the sixpence this pamphlet costs in its purchase; for it not only contains a correct translation of M. Boudault's paper, but some valuable remarks by Drs. Chambers, Ballard, and Protheroe Smith on the cases in which the new remedy is likely to be useful.

*Elements of Practical Midwifery; or, Companion to the Lying-in-Room.* By CHARLES WALLER, M.D., Obstetric Physician to, and Lecturer on Medicine at, St. Thomas's Hospital. Fourth Edition. Pp. 190. London: 1858.

THE fact that this little work has reached a fourth edition is a sufficient proof of the estimation in which it is held by the Professional public to whom it is addressed. It contains three plates illustrating the stages of natural labour. It is written in an easy and very lucid style, rendering it a valuable assistant to the student and young practitioner.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### LAUDANUM DRESSINGS IN PAINFUL AFFECTIONS OF THE UTERUS.

By M. ARAN.

M. Aran in this paper describes a means of locally applying laudanum, that he has found useful in several hundred affections of the uterus. The object being to retain this substance in contact with the os uteri and upper part of the vagina, a magma is produced by means of an inert powder. The cervix being exposed by means of the speculum, from thirty to fifty (and sometimes more) drops of laudanum are allowed to flow to the bottom of the instrument. After bringing the fluid in contact with the surface by alternately opening and closing the valves of the speculum, a few drachms of starch are placed at the bottom of the instrument by means of a spoon or spatula, so that the laudanum may become absorbed by this, and, this taking place very speedily, the speculum is then withdrawn. While this is doing the starch is kept in the vagina by charpie or cotton, which, indeed, may be left at the entrance of the vulva, if the size of this leads to the fear that the substance will fall out when the patient stands erect. Absorption takes place slowly, one hour, and sometimes three

or four hours, being required before the first assuaging effect is perceived. No ill effects, whether from excess of narcosis or disturbance of digestion, have been observed. The application may be repeated every other day, or even every day, the patient in the interval well washing out the previously applied magma.

This dressing is applicable to those affections of the uterus and genital organs which, after active inflammation is subdued, still manifest a painful hyperæsthesia. But it is especially useful in the hyperæsthesia which sometimes accompanies uterine deviations, or the morbid adhesions contracted by the uterus with the other pelvic organs. In these cases of chronic cellulitis, as also in chronic inflammation of the ovary and the tube, it does good service by allaying morbid sensibility. In such cases a precise indication may be often sought for in vain, nothing indicating inflammation or congestion, or these having been subdued by local bleeding. A few laudanum dressings quickly bring relief, and that not for some days only but for entire months. "I have found another morbid occurrence remarkably modified by these dressings, viz. a special condition of the entire uterus, frequently met with in women of a certain age, and which perhaps is in some cases connected with the formation of small fibrous tumours. In these patients the finger and the speculum fail to detect any sign of inflammation or congestion; and yet so excessive is the morbid sensibility, that a false step or violent shock excites sensibility on every side. In other words, it is a most complete state of hysterælgia; a few laudanum dressings soon allay this sensibility and pain, the patient exchanging in a few days a state of extreme suffering and uneasiness for one of remarkable comfort." M. Aran has made but little use of this means in ulcerated cancer, fearing hæmorrhage from the employment of the speculum; but in non-ulcerated cancer and epithelioma and in fibrous tumours, this means has afforded more marked relief than any other he has tried. It does not cure these patients, but to afford them relief is to do much.—*Bull. de Thérap.* tom. liii. p. 481.

#### EXCERPTA MINORA.

*Liniments in Eczema.*—Oil of sweet almonds 10, glycerine 10, and oxide of zinc 5 to 10 parts. To be applied after the acute stage has passed, or when the inflammation has become abated, and the scales detached by cataplasms. If in the chronic stage the effect is inefficient, add from 2 to 4 parts of sublimed sulphur. The formula is especially useful in eczema of the anus and chapped nipples.—*Bull. de Thérap.* Feb. p. 111.

*Iodide of Starch in Ulcers.*—This is prepared by making a paste of 1 part starch and 3 of water, with which are thoroughly mixed, when cold, 8 of tincture of iodine. This, spread on charpie, is applied to the ulcers, employing a little pressure, so as to mould it on to the surface of the ulcer. It may remain thus applied during several days. Still, as it excites abundant suppuration, it must be watched, removing it if it becomes painful or the discharge is great. In general we may wait until the discharge or the progress of the cure detaches the application. M. Castax, an Army Surgeon in Algeria, has employed it with great success for several years past in ulcerated wounds and all descriptions of old ulcers.—*Gaz. des Hôp.* No. 26.

*Digitalis in Migraine.*—M. Debout relates several cases showing the good results which attend the addition of digitalis to the anti-periodics employed in the treatment of this troublesome affection. He was first induced to employ it from having observed the regularising effect it exerts upon the menstrual function of women submitted to its influence; and afterwards extended its application with advantage to other cases of migraine than those which seemed to be dependent upon, or aggravated by, disorders of this function. His first formula consisted in sulph. quin. 46 grains, pulv. dig. 22 grains, cons. q.s., in 30 pills, one every night. But this was subsequently modified according to the indications in different cases.—*Bull. de Thérap.* tom. lii. p. 114.

*Retention of Urine produced by large Doses of Quinine.*—M. Ségalas has already drawn the attention of Practitioners to the fact, that quinine administered for intermittent fever will sometimes induce cystitis; and in this paper Dr. Brun relates an interesting case, in which large doses of this substance produced retention of urine in a patient suffering

from stricture; and this, joined to other cases which have been published, leads him to caution against employing large doses of quinine, except in very urgent cases, without first inquiring whether some affection of the urinary organs, quiescent or otherwise, exists. On the other hand, M. Serres, of Dax, relates several cases in which the principal means of relieving dysuria and retention of urine consisted in the administration of considerable doses of quinine.—*Bull. de Thérap.* tom. liii. pp. 273, 418.

*Milk Diet in Dropsies.*—Some time since, M. Serre advised the employment of abundant and exclusive milk diet, with or without a raw onion, as almost a specific in anasarca. M. Guinier finds that under certain circumstances it proves an efficacious remedy. He says it is especially adapted to the hyperæsthenic form of dropsy, and is therefore often of, at all events, temporary utility in the dropsies dependent upon Bright's disease.—*Bull. de Thérap.* tom. liii. p. 397.

*Labour impeded by a Calculus.*—M. Monod, called to a case of midwifery, found the head of the child thrusting down the anterior-inferior wall of the uterus upon a tumour, which was evidently constituted by a calculus enveloped by the bladder, and forced into the vagina by the pressure of the head. It was easy to feel that this was a very large mural calculus, and it evidently presented an insurmountable obstacle to delivery. The woman having been brought under the influence of chloroform, an incision was made from before backwards on the projecting portion of the tumour, constituted by the anterior wall of the vagina and *bas-fond* of the bladder. The latter was so closely applied around the calculus that it was impossible to use the forceps; and it was only after long and painful efforts that it could be brought out by the fingers. The os uteri being very dilatable, the forceps were at once applied, and a still-born child was easily delivered. The incision healed completely in two or three weeks, and the woman, since observed, continued quite well.—*Bull. de Thérap.* tom. liii. p. 373.

## GENERAL CORRESPONDENCE.

### NITRO-GLYCERINE.—GLONIN.

[To the Editor of the Medical Times and Gazette.]

SIR,—The extraordinary effects ascribed to glonoin by Mr. Field, in a communication inserted in the *Medical Times and Gazette* of the 20th instant, induced me this morning to undertake a series of experiments, in conjunction with Dr. Harley, of University College, with the view of testing the effects of this agent; and as the subject is one which has attracted some attention, it may be useful to make the Profession acquainted with the results at which we arrived. I leave to Dr. Harley to describe the details of the experiments in his own case, as also of those on a rabbit to which we administered this substance, and shall merely premise that the glonoin which I swallowed was pure glonoin, obtained from Morson's of Southampton-row, diluted with 10 parts of rectified spirit; whilst the glonoin which Dr. Harley took was pure glonoin, obtained from a homœopathic chemist, diluted with 6½ parts of rectified spirit. Eight drops of this latter solution added to 92 drops of rectified spirit would form (so the homœopathic chemist stated) the solution of glonoin known to homœopaths and described by Mr. Field as glonoin of the first dilution. It would contain 1 drop of pure glonoin to 99 of spirit.

Our experiments commenced at 12.45 o'clock, at which time my pulse was 80, and my respirations were eighteen in a minute. I began by taking 2 drops of a solution containing 1 drop of pure glonoin in 99 of rectified spirit—the solution employed by Mr. Field. It was sweet to the taste and warm, and imparted a flavour or odour somewhat resembling chloric ether. In the course of a minute I felt, or fancied that I felt, some fulness in the head, but was not conscious of any other unusual sensation. At four minutes past 1 o'clock I took 2 drops of the solution obtained from Morson's, or in other words, one-sixth of a drop of pure glonoin, which is equal to 17 drops of the solution spoken of by Mr. Field. It was very sweet, and pungently hot to the tongue and throat, giving rise to a burning sensation which lasted several

minutes. At six minutes past one my pulse had risen to 96, and I felt, or fancied that I felt, increased fulness about the head, but without giddiness or confusion of thought. My pupils were not affected, and I did not experience any unusual sensation beyond that just referred to. At 1.15 o'clock I took four more drops of Morson's solution, or in other words, one-third of a drop of pure glonoin, which is equivalent to 33½ drops of Mr. Field's solution. At 1.18 o'clock my pulse was still 96; my respiration remained tranquil; my pupils were unaffected, and I was not conscious of any unusual sensation, except a sense of slight fulness in the head. As no further symptoms occurred, at 1.30 o'clock I swallowed six drops of Morson's solution, or in other words, half a drop of pure glonoin, which is equivalent to fifty drops of Mr. Field's solution. It was intensely hot to the mouth and gullet, rendering it necessary for me to swallow half a glass of water. I felt somewhat nervous; and for a few moments the surface of my body became covered with a clammy perspiration; my pulse intermitted occasionally, and I experienced, or fancied that I did so, an increase of fulness about the head; but my pupils remained unaltered, and in no other respect did I perceive any difference from the effects produced by the former and smaller doses. In a few minutes the nervousness passed off, and at 1.35 o'clock my pulse was 90 and regular. At 1.40 o'clock my pulse was 86, and my respirations were sixteen in a minute. At 1.50 o'clock my pulse had fallen to 80, or the standard at which it was found before the commencement of the experiments.

Thus within the space of one hour I took rather more than one drop of pure glonoin, which is the amount contained in eighty drops of the solution spoken of by Mr. Field. This would appear conclusive as to the fact that whether in weak solution (1 in 100) as employed by the homœopaths, or in a strong solution (1 in 6) glonoin does not produce the effects which have been ascribed to it; and that, contrary to what has been stated by Gmelin and implied by Mr. Field in his recent communication, it may be taken with impunity in considerable quantity. Whether the acceleration of the pulse which was observed in the first instance was attributable to the effect of glonoin, is a question which requires further experiments to determine. My own impression is, that it was purely the effect of the nervousness or excitement resulting from the experiments in which we were engaged, for had it been otherwise it is not probable that the pulse would have fallen to its natural standard within so short a period after taking the larger doses. The fulness in the head may have been attributable in part to the same cause, but some discomfort about the head, not amounting to headache, continued for several hours afterwards, and I cannot help thinking that it is fairly referable to the effect of the glonoin I had taken. I will only add, that for some weeks I had been suffering from slight bronchial irritation, with frequent expectoration of thick mucus, and that since I swallowed the glonoin I have not had occasion to cough or expectorate. I am, &c.

HENRY WM. FULLER, M.D., Cantab, F.R.C.P.

Physician to St. George's Hospital.

13, Manchester-square.

Monday evening, March 29, 1858.

[To the Editor of the Medical Times and Gazette.]

SIR,—In last week's number of your Journal appeared a very interesting communication on the toxic and medicinal properties of the substance to which homœopaths have given the name of glonoin. The author described the effects produced by this substance upon himself and other animals, and, strange to say, the results obtained seemed to indicate that glonoin, although poisonous to man, was yet perfectly innocuous in its effects upon other animals.

The effects so graphically described by Mr. Field are scarcely those one would expect to find produced by so small a quantity of a homœopathic drug; and I must candidly admit, that if all infinitesimal doses are equally potent, my ideas of homœopathy require to undergo a radical change. The abovementioned two drops of liquid were taken from a solution consisting of one drop of glonoin dissolved in ninety-nine drops of rectified spirit; consequently the alarming effects spoken of were produced by only one-fiftieth of a drop of pure glonoin. From another part of the communication of Mr. Field, it would appear that glonoin is a very powerful

poison; but, on reading a little further, we find that animals "appear to be almost unaffected by this drug."

Being unacquainted with any substance whose toxic effects are entirely limited to the human organism, (a) I was naturally anxious to repeat Mr. Field's experiments. Consequently I lost no time in procuring at a homœopathic pharmacy a bottle of glonoine, of the same strength as Mr. Field's. I began by touching my tongue with the cork moistened with the solution; but experiencing no effect beyond that which usually follows the application of alcohol or ether to the tongue, I boldly put a couple of drops in my mouth. At first I felt a kind of sweet and burning sensation, and soon after a sense of fulness in the head, and slight tightness about the throat, without, however, any nausea or faintness. After waiting a minute or two these effects went off, and I could not help thinking that they were partially due to imagination. Determined to give the thing a fair chance, I swallowed five drops more, and as these did not cause any increased uneasiness, I took, in the course of a few minutes, other ten drops of the solution. Being at the time quite alone, I became somewhat alarmed lest I should have taken an over-dose, and very soon my pulse rose to above 100 in the minute. The fulness in the head, and constriction in the throat, I thought was more marked than after the previous dose. In a minute or two, however, my courage returned, and the pulse soon fell to 90. The fulness in the head lasted some time, and was followed by a slight headache. Next day I repeated the experiment upon myself by taking ten-drop doses, and finding no bad effects to result from them, I tried the substance on some of my friends, without saying what sensations might be expected to arise from it; and I may cite the following as a good example of an experiment unaffected by imagination:—

To Dr. von F., a strong, healthy gentleman, aged 26, respirations 28, and pulse 84 in the minute, I gave ten drops of the solution. After waiting five minutes without witnessing any effect, I administered to him other eighteen drops of the glonoine in a little water. In about a quarter of an hour the pulse was noticed to be slower; this, however, was, no doubt, caused by his sitting quite still. The respirations remained as before, and neither fulness in the head nor constriction in the throat was complained of. Upon the tongue of another gentleman (a Medical man) who was equally ignorant of the contents of Mr. Field's communication, I allowed two drops of glonoine to fall; after waiting five minutes without any peculiar sensation being felt, I gave him eighteen drops of the solution, and in five minutes more, as there was still not the slightest effect observable, I again gave him other eighteen drops. The pulse and respirations were carefully watched during a quarter of an hour longer; but as absolutely nothing was either felt or observed, my friend went home. Having been thus unsuccessful in obtaining any decided effects from the employment of glonoine procured at the homœopathic pharmacy, I obtained some of the pure substance from Mr. Morson, in Southampton-row. While standing in Mr. Morson's shop, I took by degrees a drop of the perfectly pure material, and found that, on bringing it in contact with the tongue, it at first gave rise to a sweet flavour, which was rapidly followed, however, by a most disagreeable, acrid, burning sensation. The latter lasted during several minutes. Immediately after I had taken the drop, which was equal to 100 drops of the solution previously employed, I felt my pulse, and found it 106 per minute. I imagined, too, that I felt fulness in the head, and some tightness about the throat; but as these effects gradually passed off in the course of a few minutes, I thought that they were most probably due to fear and imagination.

On the 29th instant I made, in consort with Dr. Fuller of St. George's Hospital, some experiments with two different solutions of glonoine. One contained one drop of glonoine dissolved in ten of spirit; the other, one drop dissolved in six and three-quarters of spirit. As Dr. Fuller will, in a separate letter, describe the effects produced upon himself by glonoine, I shall limit my remarks to a description of my own sensations. At 12.45, my pulse being 80, my respirations 22 per minute, I took of the solution containing one part in six and three-quarters of spirit, a quantity equal to one-sixth of a drop of pure glonoine, which would be equal to sixteen and a-half drops of the solution used by Mr. Field. At one

o'clock my pulse had risen to 90, but the respirations were about the same. I felt some fulness in the head, and slight tightness about the throat. At 1.5 I took one-third of a drop (= thirty-three drops of Field's solution). In three minutes afterwards my pulse was 98. The other effects continued as before. At 1.16 I took another half-drop, (= fifty drops of Field's solution,) and in four minutes afterwards, my attention having been directed to another subject, my pulse had fallen to 94. At 1.30 I took a whole drop of pure glonoine, (= 100 drops of Field's solution,) and in six minutes afterwards my pulse had got up to 106 per minute. None of the other effects were increased. Ten minutes later, when I had become convinced that I ran no risk in thus rapidly augmenting the dose, my pulse fell to 78, while the respirations were 18 per minute. I have, therefore, no hesitation in saying, that the effect upon the heart's action was entirely due to fear. The head and neck sensations, however, I think, are too constant to be attributed to the same cause, although I have no doubt the imagination exaggerates them. During the three-quarters of an hour that this experiment lasted, I had taken altogether a quantity of glonoine equal to 199½ drops of the solution used by Mr. Field, and of which two drops were sufficient to produce in him symptoms of narcotic poisoning.

While Dr. Fuller was with me at University College, we gave in the course of fifteen minutes a quantity of an alcoholic solution of glonoine, equal to three drops of the pure substance, to a small sickly looking rabbit. The animal was kept under observation for more than an hour without any effect being observed.

To a frog we gave at 1.20 some of the solution equal to two-thirds of a drop of pure glonoine. At 1.34 he was noticed to be in a convulsion. This experiment, however, scarcely deserves to be mentioned, as it is impossible to say whether the alcohol or the glonoine induced the tetanic state.

Through the kindness of Mr. Spencer Wells, who gave me a quantity of pure glonoine, prepared by Mr. Squire, I was enabled to perform the following experiments. To a middle sized dog I gave fifteen drops of the undiluted substance, and in three minutes afterwards I gave him other ten drops—in all, a quantity represented by 2500 drops of the solution employed by Mr. Field, and although the animal was most carefully watched during a couple of hours, no effect was detected beyond what was produced in the mouth by the acidity of the drug.

At 11.45 I put two drops of pure glonoine into the mouth of a frog. At 12.7 he was seized with convulsions. The fore-legs were firmly clasped on his breast, and the hind-legs were stretched straight out. The slightest touch or even blowing with the breath upon him was found sufficient to induce a spasm. The tetanic state differed from that produced by strychnia, inasmuch as the spasms were of very short duration, almost instantaneous, and when the animal was left quiet recurred at regular intervals—eighteen in the minute. In about an hour and a half after the administration of the toxic substance, the frog was found flaccid, and nearly dead. When touched, however, slight spasm could still be induced.

To another frog I gave three drops of pure glonoine, and in twelve minutes afterwards he was found convulsed. I watched him for nearly an hour, and he presented symptoms very similar to those already described as occurring in the previous case; the only difference being that he frequently croaked, and occasionally made a sort of screaming noise. I observed that the mucous membrane of the frog's mouth was somewhat inflamed by the drug,

I may mention that the pure glonoine which Mr. Wells gave me, as well as that got at Morson's, is an oily-looking, pale yellowish coloured liquid, soluble in alcohol and ether; and when first mixed with them yields a perfume similar to that arising from mellow apples. It is insoluble in water, in which it sinks to the bottom like chloroform. It has a sweet burning taste, is very slightly volatile, and inflammable.

In conclusion, I have only to remark, that I have experimented upon ten different gentlemen, with glonoine obtained from four different sources, and that I have not seen any dangerous effects follow its employment when given in the before-mentioned doses, but if taken pure great caution should be used. I am, &c. GEORGE HARLEY, M.D.

40, Somerset-st., Portman-sq., March 30

(a) The old notions about hydrocyanic acid not being fatal to hedgehogs, &c., have all proved false.

[To the Editor of the Medical Times and Gazette.]

SIR,—I see that some of your correspondents are anxious to know something about phosphate of zinc, and the so-called glonöin, or nitrate of oxide of glycy, both as regards their chemical history, and also the method of preparing them. First, then, with regard to

#### GLONÖIN.

This body was discovered by Sobrero, and described by him in the "Comptes rendus, 24, 247," and was afterwards more minutely examined by Williamson and others. It is prepared by slowly dropping pure glycerine into a mixture of equal parts of strong nitric and sulphuric acids, stirring well after each addition. Three fluid ounces of glycerine to eight of nitric and eight of sulphuric acid is a good proportion. The vessel should be surrounded with pounded ice, and any rise of temperature carefully avoided. After allowing the mixture to stand some time an oil will be found floating on the surface, which must be separated and well washed with water by decantation. The oil should then be dissolved in a small quantity of ether, and the ether allowed to escape by spontaneous evaporation.

The substance thus obtained is a heavy oil, of an amber colour, very slightly soluble in water, but exceedingly so in ether. It has a sweet, pungent, aromatic taste, and when placed on the tongue, even in very small quantity, produces headache, which lasts for several hours. When a small piece of blotting-paper, moistened with a few drops of it, and placed upon a smooth anvil, is struck with a hammer, a violent explosion is produced. If, on the contrary, a little of it on a piece of paper is introduced into the flame of a candle, the combustion takes place quietly. When boiled with aqueous potash, nitroglycerine is decomposed, glycerine and nitrate of potash being formed.

Submitted to analysis, this body is found to consist of

that is to say, it is glycerine in which three equivalents of hydrogen have been replaced by three equivalents of hyp-nitric acid, three equivalents of water being formed at the same time, thus:—

*Glycerine.*

*Nitroglycerine.*

I may mention, that the proper name of this substance is nitroglycerine. The word "glonöin" gives no idea of its nature, and the term "nitrate of oxide of glycy" is quite inadmissible.

#### PHOSPHATE OF ZINC.

Ordinary phosphate of zinc may occur in two forms, either as triphosphate or as diphosphate. If a solution of sulphate of zinc is poured into a solution of phosphate of soda, a fine white crystalline powder is obtained. This is the triphosphate, the composition of which is expressed by the formula:—

If, however, a solution of four parts of crystallized phosphate of soda in thirty-two parts of hot water is poured into a solution of three parts of sulphate of zinc in thirty-two parts of hot water, and the whole allowed to cool, the diphosphate of zinc is deposited in shining laminae.

Both these salts are readily soluble in dilute acids; but the diphosphate dissolves to a greater extent than the other, inasmuch as it already contains more phosphoric acid, and its crystalline form is a guarantee of purity. A fluid ounce of the dilute phosphoric acid of the Pharmacopœia dissolves 40 grains of the diphosphate; and in this solution both the acid taste of the phosphoric acid and the styptic taste of the zinc are singularly modified and diminished. It would be, I think, an agreeable form for administration.

I am, &c. W. STEVENS SQUIRE, Ph. D. F.C.S.

277, Oxford-street, March 30.

#### A FICTITIOUS DIPLOMA.

[To the Editor of the Medical Times and Gazette.]

SIR,—I was gratified to find the University of St. Andrews had "requested" Dr. Day to "make public a gross attempt

at fraud" in one Thomas O'Grady, "falsely claiming to be a graduate" of their ancient University.

I can sympathise with the idea the learned Professor apparently entertains, that to "make public" such conduct might shame the evil-doer; and in the case of honest men publicity is doubtless a terrible punishment for any rash or foolish action; but I cannot for one moment imagine that the mere "exposure" is any punishment to one so abandoned as to make this nefarious "attempt." On the contrary, if all there is to fear from such conduct be an "exposure" in the columns of the *Medical Times and Gazette*, there are many who would readily commit the fraud and scorn the consequence. Now the law places in the hands of the Senate a remedy which is far more likely to instil a wholesome fear; and I trust Dr. Day will urge upon the Senate its manifest duty, to take proceedings against the delinquent, both for the sake of protecting the graduates and deterring from a repetition of the misdemeanour, or forgery, whichever the law may pronounce it.

Allow me also to suggest another mode of preventing future attempts, or at least rendering them less likely to succeed, viz. by giving greater publicity to the names of graduates and the proceedings of the University. The present "Calendar" I consider a disgrace to its compilers; being a mere list of officials, followed by the list of graduates, and one or two specimens of "examination papers" of the Faculty of Medicine, but not one of either of the other faculties. For this "Calendar" the price is three shillings, while the "Catalogue of the College of Surgeons" may be had for one shilling, with ten times the amount of letterpress. If Dr. Day will compare his Calendar with that of the London University he will at once see the superiority of the latter.

It is generally understood that a University Calendar should contain full information respecting the University regulations and government, its officers and Professors, so set forth as to be easily understood; also a list of all Graduates in Divinity, Medicine, Arts, and Laws, as well as a good supply of examination papers in all these Faculties, as well as an account of the prizes. If the Senate think well to issue a new Calendar, it should contain all the papers of the several Faculties for the last ten years or more, whether for graduation, honours, or prizes. Published at a low price, it would be extensively seen, and would apprise the public of the many improvements and the gradual progress to its present high standing of this venerable seat of learning. It should be issued simultaneously in St. Andrews, London, Edinburgh, and Dublin, and inserted in the catalogues of the four publishers.

Mr. Churchill would, no doubt, aid the University in so laudable an effort; and even if not quite a paying concern, the pecuniary loss would be more than compensated by its circulation.

Lastly, let the other Faculties be as well managed as that of Medicine. Degrees in Divinity, Arts, and Laws should be as accessible as in Medicine; but, after most carefully searching the present Calendar, I cannot find out how to proceed to obtain them.

I am, &c.

A ST. ANDREWS GRADUATE.

#### BUTCHER'S SAW.

[To the Editor of the Medical Times and Gazette.]

SIR,—May I request you will insert the following observations in reply to a letter which appeared in the last number of the *Medical Times*, relative to "Butcher's Saw." The gentleman who has thought fit to assail my claim to originality in a former number of your Journal, has the candour at least now to admit that "the artist's saw now adopted by Mr. Butcher is not the same as that invented by Mr. Graham." Shortly, Sir, after the invention of my saw, numerous modifications, as conceived improvements, were suggested; and first I shall notice the instrument depicted in Mr. Druitt's admirable Surgery.

The following letter from Messrs. Fannin and Co., the celebrated surgical instrument-makers in this city, will I conceive be very conclusive as to the source from which this modification issued:—

"41, Grafton-street, March 14, 1858.

"Sir,—In answer to your inquiries respecting the saw bearing your name, we perfectly remember giving Mr. Hutch-

neon of Sheffield an order for it, with certain modifications, which we thought would make it suitable to fit in an amputating case. He then suggested the alterations as they appear figured in Druitt's Vade Mecum, and sent us one in a rough state for approval. This we remember showing to you, when you declined to adopt the change as yours; notwithstanding we gave the order for it in the altered shape. Bearing so close a resemblance to yours, it has ever since borne your name. Neither do we remember having seen any saw like it used for Surgical purposes.

"To Dr. Butcher."

"We are, Sir, yours, &c.

"J. FANNIN AND CO."

Now, Sir, I am aware that Mr. Hutchinson supplied many houses in London with this saw; that represented in Druitt bears Mr. Coxeter's name, and must, to say the least, have been copied accurately from Mr. Hutchinson of Sheffield's pattern. A simple inspection of the instrument will prove this. In a note Mr. Druitt says, "The saw depicted above differs in some respects from that described by Mr. Butcher in the *Dublin Medical Journal*, Feb. 1855." Messrs. Fannin and Co. assert, that "bearing so close a resemblance to my saw, the instrument has ever since borne my name." The discrepancy as to name, occurring in the text and index of Druitt, is clearly the result of typographical error. Now, Sir, it is stated in the letter which has called forth these remarks, "the under-woodcut is an exact representation of the saw presented by Mr. Graham in 1831-2 to Professor Dr. Laurie of this city, and the saw itself I forward to you, Mr. Editor, for the fullest inspection." It will be at once seen that *this woodcut* has been traced from the opposite side of that represented in Druitt, and therefore from Mr. Hutchinson's pattern. There is, however, some ingenuity shown in the construction of the upper bar, for in the tracing, by particular desire I suppose, the ornamentation at either side of the screw has been omitted.

The saw, Sir, which has been forwarded to you, is *the same* as that which had been planned in Messrs. Fannin's establishment by the proprietor and Mr. Hutchinson—the *same* as that represented in Mr. Druitt's Surgery, and sold with Coxeter's name. Now, Sir, examine the instrument, and you will find, as the woodcut expresses, that the ends of the blade are not sharp, as I have advised them to be; that there is no mode of detaching the blade, (a) as I have insisted on, for passing behind bones, and as I have depicted in the representation of my saw.

With humility I ask the question, who has drawn the attention of the Profession to the practical utility of the instrument? Has Dr. Laurie or any other gentleman in the Profession written about or alluded to the instrument? Immediately after my invention of the instrument several modifications of it were made, in addition to that just detailed. As Mr. Druitt says, "Mr. Weiss has another modification of it suggested by Mr. Busk." And Messrs. Bigg and Milliken constructed another, and there are others likewise. Before it became so generally adopted, I had proved its value in many amputations—at the shoulder, the arm, the forearm, and the hand; near the hip, the thigh, the leg, in Syme's and Pirogoff's operations at the ankle-joint and the foot: in frequent resections of the knee, the elbow, and the wrist-joints, as likewise at the metacarpal and metatarsal articulations. Not until I had demonstrated the practical utility of the saw which I had invented do we find any notice of the various modifications of it which quickly came into the market. I consider the instrument which I first invented, figured, and wrote about as superior to every other, and continue to use it in preference to any.

I maintain then, Sir, that I am entitled to the originality of the instrument, in all the particulars to which I have adverted in my several communications. I have been thus compelled, Sir, in order to establish my rightful claims, to enter into a correspondence which otherwise I should have shrunk from; but the step which I have taken was due unto myself and to the right decision of the Profession, to which I fearlessly appeal.

Feeling deeply obliged for the space which you have allotted to me, I beg to decline any further correspondence with Mr. Hilliard, the instrument-maker; but if any member of

(a) Mr. Butcher is mistaken here. The blade can be easily detached.—Ed.

the Medical Profession wishes for any further discussion on the subject, I shall be happy to enter into any additional explanation that may be deemed necessary.

I am, &c.

RICHARD G. H. BUTCHER.

19, Fitzwilliam-street, Merrion-square,  
Dublin, March 15, 1858.

### PROLAPSUS UTERI.—PERINEO-PLASTIC SURGERY.

[To the Editor of the Medical Times and Gazette.]

SIR,—In reference to a letter from Dr. Savage, which appeared in your Journal of the 20th ultimo, I beg simply to remark that I have been as scrupulously careful as it has been possible for me to be; having applied directly, or indirectly, to every patient whom I could trace, in private or public practice: but unfortunately, contemporaneously with the painful attack which was made upon me by a late House-Surgeon in charge of my cases at St. Mary's Hospital, two of my case-books, containing cases of three years, disappeared; and although I have taken every means to recover them, I have not up to the present moment succeeded in doing so. The Profession will therefore see that I have no power to give further or fuller details.

I am, &c.

17, Connaught-square, Hyde-park. J. BAKER BROWN.

### THE LATE DR. SCHÆPF MEREL.

THIS eminent Physician expired at his residence, Oxford-street, Manchester, on the 12th inst., in the 54th year of his age.

Brief as was the period of Dr. Merel's sojourn in this country, his loss will be deeply lamented by many sincere friends, and not a few ardent admirers among literary and scientific men, both in his adopted city and in places remote from the sphere of his daily avocations. On the Continent, where his scientific merits were well known and appreciated, the event of his death will be deemed a calamity to the branch of science in the cultivation of which he was more immediately engaged.

He was cut off, it may be truly said, in the prime of life; for, although in his 54th year, his physical energies and mental activity were equal to those of one many years younger. His health had been in an unsatisfactory state for several months previous to his last illness. In the autumn of the past year, when complaining of faulty digestion, and the necessity of a carefully regulated hygiene, his Medical adviser recommended him to spend a few weeks in the country, believing, from a manifest change in his complexion, tint, that his biliary functions were deranged. This phenomenon, however, the patient asserted, was attributable to over-exertion and loss of rest, as he had not naturally the bilious temperament. After a shooting excursion of three weeks in Scotland, he returned in improved health and spirits, and continued to discharge his duties with his usual energy, and but little complaining, until within six weeks of his decease. His restlessness at night had for a length of time been remarkable. Possessing a constitution and temperament of a type requiring but little sleep comparatively, the need of this natural restorative seemed to have almost fled, as he declared during his illness that in the course of the past winter he did not remember to have fallen into a state of unconsciousness during any one night, although he rose in the morning not unrefreshed. His custom was to retire late to rest—one, two, or three hours after midnight—and to rise early. But latterly, while in bed and apparently soundly sleeping, he was fully conscious of everything passing on around or near him, and could rouse himself at any moment. His mind did not cease to be active during this imperfect repose, ever dwelling upon what had engaged him during the day, and arranging plans for the future. It seems never to have occurred to him that this state of insomnia might owe its existence to physical malady, but was attributed invariably to moral agencies.

At the beginning of February he complained of rheumatic pains around the lower region of the chest, shooting upwards in the direction of the shoulders and arms, with occasional embarrassment in breathing. These symptoms were referred

both by himself and his Medical adviser, to diaphragmatic rheumatism, and treated accordingly. In the second week of February his health was still sufficiently firm to enable him to make a journey to London; and it appears to have been during this journey that the first indications of hepatic disease presented themselves in decided form, as he states in a letter written after his return to Manchester, to Dr. Keith of Edinburgh, and dated February 16:—"I have, for the first time, felt severe intestinal and hepatic neuralgia from the east winds, and have suffered much in the railway carriage." The treatment by means of quinine and small doses of morphine, prescribed some time previously, had been thus far continued with apparent benefit, but soon ceased to afford relief, and the pain and debility increasing, he was induced to remain indoors.

On the 23rd of February, seventeen days before death, he remained for the first time in bed, having on the previous evening discovered the existence of an unusual fulness of the epigastrium, which region, on examination, was found occupied by an unyielding tumefaction, reaching downwards as low as the umbilicus, and having a lateral extent of at least ten inches. The most prominent part of this tumour presented itself in the subternal arch; its surface was smooth over its entire extent, was very hard and resistant, and slightly tender under pressure.

Willing to believe at the time that the tumefaction consisted in a form of chronic inflammation, with persistent hypertrophy of the liver, antiphlogistic measures were employed—leeching, cupping, and vesication, with the internal administration of calomel. The treatment was soon followed by free bilious evacuations, and, during one day, by bilious vomiting. No mitigation of symptoms having ensued, however, the tumefaction remaining unaltered, it was suggested that there might be abscess, either in the liver or between it and the diaphragm, or possibly thoracic effusion. After careful auscultatory inquiry, however, the chest was believed to be perfectly normal, and on manipulating, during a sustained inspiration, fluctuation could not be detected. The presence of serous cysts or of hydatids seemed to be out of the question; and the probability of its being cirrhosis was also discountenanced by every physical and etiological argument which could be brought to bear on the diagnosis. It was at this juncture—twelve days before dissolution—that the inevitable and most painful conviction seized him, as it had previously done his Medical friend, that the disease was of malignant nature. During this, the last deliberate examination that was made, he listened anxiously to every sound elicited by percussion, and repeated some of the manipulations himself. When the possibility of malignancy was mentioned, he said that was just what he began to suspect, and settling himself down with closed eyes, expressed a wish to be left alone for a time.

Besides these negative evidences, there were others of a positive character which predicated the existence of cancer. He had frequent eructations, sometimes vomitings, of viscid phlegm mixed with black grumous spots, of a peculiarly offensive odour; the cutaneous transpiration was clammy and offensive; the urine was loaded with phosphates; the complexion of the skin, over the whole body, was of the dusky sallowness peculiar to malignancy; and the muscular and adipose tissues became rapidly attenuated.

He received the intelligence respecting the nature of his malady with firmness and resignation, as might have been anticipated; and on its being stated that it might possibly be otherwise, he shook his head doubtfully and said he was sure the diagnosis was correct. He had no fears about the change which, he believed, was inevitable, and not far distant, nor did he trouble himself afterwards about worldly matters.

He had no relish for food in any shape, and gradually declined, like one sinking from starvation. Death stole over him like tranquil slumber, without a struggle or any manifestation of suffering.

The *post-mortem* section, performed twenty-two hours after death in the presence of five medical gentlemen, revealed the correctness of the diagnosis. The liver was about twice its normal size. It was occupied throughout by encephaloid deposit,—in some places single, in others grouped; of dimensions of from the size of a pea to that of a large walnut. The smaller deposits were cheesy in consistency, but the larger ones hard and fibrous, the fibres radiating from a homogeneous semi-transparent centre, of still firmer consistency. The only portion of the organ not thus occupied, was the

lower part of the right lobe, which was extremely friable, very dark in colour, and coarsely granular.

He was interred on Tuesday the 16th; and although his funeral was intended to be strictly private, a considerable number of gentlemen, with a long line of private carriages, attended, without invitation, to follow his remains to their resting-place.

Dr. Merai was born in April 1804, at Raab, near Comorn in Hungary. His father, descended of a respectable German family, was a prosperous merchant and a man of literary attainments; his untimely end was accomplished by violence, having been decoyed and assassinated by a pretended friend for the purpose of robbery. The son's rudimentary instruction was received at a seminary in his native town, and he was remarkable for quickness and intellectual precocity. His Medical career commenced at the University of Pavia, where he first graduated. He afterwards studied at Heidelberg, Vienna, and Pesth, of which Universities also he possessed diplomas. He was Licentiate of the Royal College of Physicians of London, and member of many learned societies. From an early period he obtained the favourable notice and lasting intimacy of several men of the highest repute in the literary and scientific world, amongst whom was the celebrated Skoda, whose friendship and distinguished esteem he retained to the end of his days.

After commencing practice at Pesth he rapidly rose to distinction. A professional friend, Dr. George Keith of Edinburgh, who knew him at this period, and received his instructions, writes thus:—"When I first knew Dr. Merai in Pesth in 1839, he was Director of the Children's Hospital, Professor of the History of Medicine in the University, and editor of the only Hungarian Journal. He was then also in excellent practice, and I certainly looked upon him as the first Medical man in Pesth; though, from belonging to the popular political party, he was not, I believe, looked upon with favour at Court. I know, however, that his services were afterwards demanded by members of the Imperial family, as he attended throughout a long illness the Archduchess M., who became his warmest patroness."

About the year 1835 he founded the Children's Hospital of Pesth, one of the first of the kind in Europe; the only others in existence at that time being one at Paris, one at St. Petersburg, and one at Vienna. Into the organization of this establishment he introduced those broad principles of scientific inquiry which soon made it pre-eminent in its benevolent purposes and scientific efficiency. Of this institution he was directing physician from the period of its foundation to the time of his expatriation in 1849.

Dr. Merai's attainments in general literature were varied and extensive. His knowledge of languages might, in a measure, account for this. He was able to speak and write Latin with a facility equal to that of his native tongue, and with almost every European language he was equally familiar. The quality of his mind was eminently reflective; and, although fond of demonstration, he rarely ventured an opinion except upon facts revealed evidently to the senses. He was anxious to generalise, but would never do this but upon overwhelming and incontrovertible evidence,—so that every statement and every truth propounded by him was sure to have been maturely weighed and tested beforehand.

His manner was always that of a polished gentleman—kind, considerate, communicative without reserve, and studious to avoid the infliction of a wound upon the feelings of any, however widely differing from him in creed or opinion. Towards his patients of the poorest class who paid him nothing, this trait of character was especially noticeable; and he was always more considerate and conceding towards this class—endeavouring, while administering to their material wants, to improve their moral tone—than towards the wealthy.

During the political disturbances of 1848-9, having, unfortunately for himself, linked his fate inextricably with that of the revolutionary party, he abandoned his position and prospects in Pesth to accompany and relieve the insurgents through their disastrous campaign. He was present, with his wife and children, at the affair of Szegedin, and afterwards during the 107 days' siege of Temesvár, where want and disease thinned their numbers fearfully. During the latter part of this contest cholera was raging among them in its most virulent form, his wife, Madame Merai, being one of its early victims.

On the relief of Tamesvar by the Imperial troops under the command of Haynau, he escaped with his children to the Turkish frontier town of Widden, thence to Constantinople, where he, with others, was for some months detained. In this hurried flight he lost the whole of his available property and valuable effects, and his possessions in Pesth were confiscated. Among his losses, what he ever seemed most to regret were his note-books, containing an abundance of facts which he had industriously accumulated on the subject of children's diseases, both in public and private practice, during all the years he had been so actively employed. It is to be hoped, for the cause of science, that these records may hereafter come to light.

The writer may be pardoned for recording his deep sense of the loss which he personally, and which the needy and afflicted especially, have sustained in the premature removal of one so truly amiable, truthful, and intellectual, and whose labours were calculated to prove really beneficial both to science and humanity.

Manchester, March 26, 1858.

W.

## MEDICAL NEWS.

**ROYAL COLLEGE OF PHYSICIANS.**—At the Comitia Majora Ordinaria, held March 29th, 1858, the following Gentlemen, having undergone the necessary examinations, were admitted Licentiates of the College:—

BUCHANAN, GEORGE, M.D.  
CHILD, GILBERT W., M.B.  
GUENEAU DE MUSSY, HENRY, M.D.  
REES, JOHN, M.D.  
SANKY, W. H. OCTAVIUS, M.D.

Also, on the 26th, at a meeting of the Elects, the following were admitted Extra-Licentiates:—

HILLIARD, GEORGE RICHARD, M.R.C.S.  
ROBERTSON, W. TINDAL, M.D.

**ROYAL COLLEGE OF SURGEONS.**—The following Gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 26th inst. viz.:—

BARRETT, JAMES, Banbury, Oxon.  
BEDFORD, ROBERT JAMES, Sleaford, Lincolnshire.  
BROAD, JAMES, Stoke Newington.  
BROOKE, THOMAS THORNILEY, Stockport, Cheshire.  
FALWASSER, FRANCIS, Sherborne, Dorset.  
GARNEYS, THOMAS, Bungay, Suffolk.  
HALLOWES, FREDERIC BLACKWOOD, Canterbury.  
HEWLETT, THOMAS, Army.  
HUGHES, THOMAS HUNTER, Pwllheli, Carnarvonshire.  
HUNT, WILLIAM JAMES, Hinton Blewett, Bristol.  
KING, EDWARD PENDRILL, Chepstow, Monmouthshire.  
MAJOR, HARRY PIKE, Hungerford, Berks.  
MOSELY, ALEXANDER, Grosvenor-street, Grosvenor-sq.  
PEART, ROBERT SEPTIMUS, North Shields.  
PHILIPSON, GEORGE HARE, Newcastle-on-Tyne.  
RYATT, FREDERICK ELLIOTT, Newbury, Berkshire.  
TUCKWELL, HENRY MATTHEWS, Oxford.  
WILLIAMSON, JOHN NEWBY, Bothel, Cumberland.

Also, on the 29th inst.:—

BANNING, ROBERT JOSEPH, Fairfield, near Liverpool.  
BOUFFLOWER, JOHN, Army.  
CRANSWICK, WILLIAM NOAD, Merchant Service.  
DAKERS, WILLIAM HENRY PHILIP, Herne Bay.  
GARNHAM, RICHARD WILLIAM, Upper Holloway.  
HARPER, FREDERICK LUTHER, Aldenham-street, Somers-town.  
HARVEY, HENRY OFFLEY, Hailsham, Sussex.  
HICKMAN, WILLIAM, Brixton.  
JONES, EVAN, Hendreforgan, Swansea.  
NOEL, ANGE FERDINAND RENE, Mauritius.  
PRINCE, ARTHUR, Hartow-road.

**APOTHECARIES' HALL.**—Names of Gentlemen who passed their Examination in the Science and Practice of Medicine,

and received Certificates to Practise, on Thursday, March 25, 1858:—

ALLEN, WILLIAM EDWARD, York.  
BERRY, WILLIAM, Holmfrith.  
BROOKE, THOMAS THORNILEY, Stockport.  
GRIGO, JOSEPH COLLINGS, Exeter.  
MAJOR, HARRY PIKE, Hungerford, Berks.  
NUSSEY, THOMAS JOHN HARTLEY, Cleveland-row, St. James's.  
PEART, ROBERT SEPTIMUS, North Shields.  
PENISTON, JOHN, Worcester.  
SPRY, GEORGE FREDERICK, Cheltenham.

## DEATHS.

**DARBY.**—At Lucknow, aged 24, Edward Darby, M.D., 10th Oude Irregular Infantry, eldest son of Sydney Hudson Darby, Esq., of Tienga, Bandorah River, Australia. He was wounded by a shell, and died shortly after, in November 1857.

**FOOTE.**—On the 25th inst., at 36, Tavistock-street, Strand, John Foote, Esq., Surgeon, after a long and severe illness, in the 47th year of his age.

**HART.**—On the 24th inst., at his residence, 15, Union-street East, Spitalfields, aged 45, William Benedict Hart, Esq., Senior Medical officer to the Whitechapel Union.

**MORRIS.**—At Delhi, on the 13th January, in the 32nd year of his age, William Gardiner Morris, M.D., son of the late J. Pemberton Morris of Bolton, Pennsylvania, U.S., and grandson of the late Rev. Dr. Gardiner of Edinburgh.

**WALKER.**—March 9, at Orchard House, Teignmouth, Edward Dering Walker, Esq., M.D.

**WATT.**—Suddenly, at 15, Lansdowne-crescent, Glasgow, on the 22nd inst., Peter Fullarton Watt, Esq., M.D., late of Demerara.

## APPOINTMENTS.

The Queen has been pleased to appoint William Lawrence, Esq., F.R.S., to be one of Her Majesty's Sergeant-Surgeons in Ordinary, in the room of Benjamin Travers, Esq., deceased.

**THE LATE DR. ROLPH'S FAMILY.**—Additional subscriptions received at the *Medical Times and Gazette* office:—

Edward Ambler, Esq.	£1 1 0
Henry Sterry, Esq.	1 1 0
Thomas S. Upton, Esq.	10 0

**ROYAL MEDICAL AND CHIRURGICAL SOCIETY.**—The following gentlemen will be balloted for as Fellows of the Society, on Tuesday evening, April 13th, 1858:—William Chapman Begley, Teofilo de Lima, Edward Stephens, and J. F. Streetfield. The ballot will be opened at half-past seven o'clock, and will close at half-past eight precisely.

**SHIPS OF WAR FOR HOSPITALS.**—In consequence of the number of troops now in the Hospitals at Chatham, and the expectation of a very large arrival of invalid troops from India in the month of April next, the Board of Ordnance made application to the Lord Commissioners of the Admiralty for assistance, in granting the use of a large class war ship; their lordships very readily offered the Powerful, 84, and the Superb 80; both ships are immediately to be taken up and fitted for the accommodation of 800 men.

**M. GROUX AT MANCHESTER.**—On Thursday there was a numerous gathering of the Medical Profession of Manchester at the Royal Institution, on the occasion of a visit by Mons. Groux, the subject of a congenital fissure of the sternum, so fully described in our last volume. Mr. Thomas Turner presided. M. Groux afforded the Medical gentlemen an opportunity of making their observations upon his chest. By means of Dr. Alison's sphygmoscope, by delicate flexible stethoscopes, and by feathers made to adhere over the fissure, M. Groux demonstrated the correctness of the explanations generally offered of the phenomena which his case presents. The pulsations in the right auricle were very distinctly visible, and were found to be perfectly simultaneous with the pulse at the wrist.

THERE was a concert a day or two since in the Austrian State Lunatic Asylum, and Staudigl, the once celebrated singer, sang the "Chapel in the Wood," by Schubert, to the great delight of his fellow-patients.

**CASE OF GASTROTOMY.**—The operation of opening the stomach with the view to establish a fistula in order to the introduction of food, was performed the other day at Guy's. We hope to give its details next week. The patient was a man, under Dr. Habershon's care, on account of cancer of the œsophagus, which prevented him from swallowing, and also rendered it almost impracticable to employ the tube. The operation was performed by Mr. Cooper Forster, on Friday last. The poor fellow, who was already in the last stage of inanition, sank on the third day.

**MR. TUCKER'S ANTICIPATED ELECTION AS A PENSIONER OF THE ROYAL MEDICAL BENEVOLENT COLLEGE.**—Mr. Tucker, the founder of the Epidemiological Society, has, we are glad to say, in great measure recovered from the calamitous disorder with which he had for some time been afflicted. But his advanced years (67), and the broken state of his constitution, preclude all hope of his ever again returning to practice. A Committee, consisting of Dr. Babington, 31, George-street, Hanover-square, W.; Dr. Camps, 40, Park-street, Grosvenor-square, W.; Mr. Hunt, 23, Alfred-place, Bedford-square, W. C.; Dr. McWilliam, 14, Trinity-square, Tower-hill, E. C., and others, has, therefore, been for some time engaged in raising, by subscription, a sum sufficient to purchase a small annuity, so as to enable Mr. Tucker to enjoy the quiet and comforts of the Asylum of the Royal Medical Benevolent College during the remaining years of his life. The members of the Committee earnestly beg the assistance of their brethren and others, who are subscribers to the Institution, in securing Mr. Tucker's election as a pensioner in May next. For that purpose the members will gratefully receive proxies in aid of their benevolent object.

**INFLAMMATORY AND OBSTRUCTIVE DISEASES OF THE CÆCUM.**—Dr. W. R. Rogers has recently brought before the Medical Society of London, a paper, to show that the cæcum may be the seat of fatal diseases, without any other part of the digestive tube being implicated. It is the viscus in which the last act of digestion is performed, secreting an acid, albuminous, and solvent fluid, and pouring out of its numerous follicles an unctuous and oily material with hydrosulphuretted gases, to be eliminated from the economy, being, like the lungs, kidney, and skin, a depurating organ. When costiveness exists, these excretions may be reabsorbed and contaminate the blood. The symptoms of inflammation of the cæcum may begin mildly, and gradually proceed to greater intensity, or they may in excitable subjects be violent from the onset. There is but little febrile disturbance compared with the local pain and suffering, less anxiety of countenance than in enteritis, pulse not so small or much quickened at the commencement; there is great tension and tenderness over the cæcum, so that the least pressure cannot be borne; there are no rigors, the pain constant, does not intermit, and its area goes on increasing till the whole abdomen is involved, but the ileo-inguinal region is always the most tender part. There is obstinate costiveness, and later sickness and vomiting, especially when drastic purgatives have been persevered in. Patients when suffering from these acute diseases, will lie on the back, inclined to the right side, body bent, thigh drawn up; the countenance has not the anxious aspect of enteritis. If neglected or wrongly treated, the abdomen becomes tense and tympanitic, and general enteritis or peritonitis may supervene. Should the appendix be inflamed, all the symptoms are more acute and likely to terminate fatally. In the progress of these diseases, adhesions are often formed in its interior or to other parts, and the cellular tissue around may inflame, suppurate, and give rise to abscess. These inflammations may terminate either in resolution, ulceration, perforation, and abscess, which may tend upwards or downwards and require to be opened; they may open externally or find their way into other parts of the intestinal canal, the patient recovering, or may die worn out by the discharge. Should the ulceration open into the peritoneum, without adhesion to the abdominal walls taking place, peritonitis of a diffused and fatal nature will be set up, as in one of the cases related by the author. This termination is fortunately rare, though not uncommon in typhoid and dysenteric fevers. The author in the acute cases advises

leeching, fomentations, soft warm poultices, mild effervescing aperients, and large bland enemata, sometimes with castor oil and turpentine; if these means fail, calomel and opium, or opium alone, but all drastic purgatives are to be avoided. The careful and repeated use of O'Beirne's tube has been of essential service, and has often alone cured cases of simple obstruction and constipation that had resisted other treatment. The author thinks the use of this instrument is much neglected, and lays great stress on cautions dieting, which should be for a long time of the most simple and bland form, arrow-root, rice, milk, and eggs, subsequently beef tea and jellies. In chronic inflammation the author relies on blisters, iodine liniments, and saline aperients, with strict attention to dietetic rules.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, March 27, 1858.

### BIRTHS.

Births of Boys, 1000; Girls, 924; Total, 1924.

Average of 10 corresponding weeks, 1848-57, 1615.

### DEATHS.

### TO CORRESPONDENTS.

Ozone.—Miller's Chemistry, price £2 6s. 6d.

Mr. Eaker Brown's cases of Vesico-Vaginal Fistula are unavoidably delayed until next week.

Dr. Rigby's paper on the "Squatting Uterus" is in type.

Mr. Field will see that the publication of his letter was unnecessary after the full particulars given by Dr. Squire.

Mr. Page's paper, "On some Affections of the Urinary Bladder and Urethra," shall appear next week.

A *Quæst-Mater's* letter shall be published if he will append his name to his communication.

Mr. Smith's (*Southam*) letter arrived too late for insertion this week.

*Chirurgicus* (*Edinburgh*).—The details of the arrangement as to the Clinical Chair between Messrs Russell, Syme, and Liston, are very amusing, but are scarcely adapted to these columns.

Mr. Bastick's paper on the Chemistry of Caustics shall appear next week.

ERRATUM.—Page 321, col. 1, line 26, for eight inches, read one inch.

#### CHLORO DYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Being somewhat interested in the "Chlorodyne Discussion," allow me to ask, "Who is Dr. J. Collis Brown?" Let him come forth (if he is, as stated, a Medical Officer in Her Majesty's service) to do battle for the "Incomparable Chlorodyne;" and, if he possesses the wonderful properties enumerated in Mr. Davenport's advertisement, he need not be ashamed. Will Dr. Collis Brown disprove satisfactorily and clearly that Dr. Medlock's and Dr. Horsley's analysis are not near the mark?

I am, &c.

EUPHIDES.

#### BLEEDING IN ARMY MEDICAL PRACTICE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your impression of March 13th I have observed a letter from the inquiring pen of Dr. W. O. Markham, under the title of "Bleeding in Army Medical Practice." I conclude this gentleman must be one who for many years past has been out of the way of knowing the revolutions produced by scientific researches in the action of remedies, and the inherent power of the "vis medicatrix nature" in the cure of disease. The "darkness" which he presumes to apply to the Profession generally, with reference to the medical treatment of the soldier when attacked by acute diseases, I should hope can only exist in his own distorted imagination, and such errors I would beg to remind him are often the result of "curious examinations," similar, probably, to his admitted style of examination into the case of the magnificent-looking Guardsman, whose case he was permitted to witness. The mortality from pulmonary diseases among the Guards stationed in the metropolis is, unfortunately, very high; but the Medical officers have the satisfaction of knowing that it is probably to be attributed to causes over which neither they nor their commanding officers can in any way whatever be held responsible for.

Torquay, Devon,

I am, &c.

JOHN WYATT,

March 29th. Battalion-Surgeon, Coldstream Guards.

#### DIPHTHERITIC CROUP.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Will you allow me to ask those of your readers whose opportunities may have qualified them to form conclusions as to the following points: What has been their experience with regard to the best remedies for diphtherite? the most successful, or rather the least unsuccessful, treatment of diphtheritic croup? and the results of tracheotomy in this disease? As the disease is so prevalent and fatal at the present time, it is desirable to bring the light of accumulated professional experience to bear upon it. My own observation as to the treatment of diphtheritic croup has been that, however carefully it may have been adapted to the constitutional and local conditions of individual cases, it has been very unsatisfactory, whatever may have been the special means used. I have lately seen two deaths of strong and healthy children in one family from this disease, which commenced in the throat, and after a few days extended to the larynx, and was then rapidly fatal.

March 29, 1858.

I am, &c. M.D.

#### ANATOMY ACT.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reviewing your number for the 16th January, 1858, I find in it an article complaining of the manner in which the Anatomy Act is wrought in London, and in the examples adduced as to the working of it in other countries, I was very much surprised to find that you entirely overlooked the existence of the Glasgow Medical schools, which schools, I can safely say from my own experience, are superiorly supplied to that of any others in Great Britain or Ireland.

Certainly I acknowledge the liberal supply which the Dublin school receive, as I have had an opportunity of witnessing it, but as to Edinburgh being adduced as an example, I am somewhat astonished. I have the pleasure of being acquainted with several students who studied their first two years in either of the Edinburgh schools, but who came here in their third year to study for the sole purpose of dissections, and from what I have heard them say I think that I am fully justified in concluding that the supply of subjects at the Edinburgh schools is very deficient indeed.

But when I consider that the Glasgow schools only used one-fourth of the subjects proffered to them last winter, and that this winter they have used about one-half,—not that the latter arose from any diminished supply of subjects, but from the increased demand for them owing to the number of students in attendance having increased considerably this winter,—I think that I am fully warranted in writing to you in favour of the Medical schools of this city.

March 23, 1858.

I am, &c. JOHN MARTIN.

STUDENT OF MEDICINE, GLASGOW.

#### CASE OF CONVULSIONS IN AN INFANT FROM OVERFEEDING—RECOVERY.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You will oblige me by giving insertion to the following interesting case:—A child, 13 months old, was attacked with symptoms of convulsions,—viz., startings, catchings, impeded respiration, etc. etc. Seven teeth had been cut with the greatest ease, but as an eighth tooth was due, and no other cause could be assigned for the above symptoms, they were attributed to the effects of some pressure on the brain from teething; accordingly a warm bath was ordered, into which the child was placed for

about ten minutes at a temperature of 98°–6. Almost immediately after being taken out of the bath, a severe convulsive fit came on—gums were lanced—and a calomel powder was administered followed by castor oil. The action of these medicines relieved the symptoms at once, and revealed the true source of the mischief—a mass of undigested food had evidently induced the premonitory symptoms, and the bath had accelerated the seizure. It was elicited, after closely questioning the child's nurse, that she had crammed him with indigestible pudding, contrary to orders, the parents wishing bottle-food only to be administered. This case possesses much interest on more points than one: it is illustrative of a very common error, that of attributing convulsions to teething as a primary cause. Teething is a natural process, and under ordinary circumstances would go on well; even in cases of delicate subjects, with suitable diet and judicious general treatment, convulsions need not be feared. It is, therefore, a libel upon Dame Nature to put down to dentition the numerous cases of convulsive fits which carry off young children; but, that such is the common opinion, the verdicts of coroners' juries amply testify. Note again.—A warm bath is the ordinary remedy resorted to in cases of convulsive attacks; but the above particulars will prove that it is necessary to pause before incurring such a risk, and whenever there is the least ground for suspicion that the stomach or bowels may be the seat of the disorder, it is a safe course to make use of an active purgative without delay. Such cases as this point very forcibly to the need of training young women to the responsible duties devolving upon them as nurses to infants. Considering the great ignorance that prevails among persons who undertake the feeding and management of young children, and the lamentable consequences of such ignorance, it is a wonder that the necessity for the establishment of institutions with that object is not more generally felt and insisted upon. Dr. Routh, in his admirable papers, which he is now publishing, proves that "the high rate of mortality among infants is chiefly attributable to improper diet and injudicious method of feeding. Another cause of increased mortality is the substitution of a hired wet nurse's milk for the mother's milk," thus establishing the fact that if a mother cannot or will not give nourishment to her offspring, bottle-feeding judiciously managed would promise more certain success in promoting the child's health and vigour than consigning it to the hired breast.—The foregoing case and remarks will, Sir, I am sure possess some interest to those of your readers who are giving their attention to the important matter of infantile alimentation, especially to those who have any intention of applying the result of their study to some practical purpose.

I am, &c.

M. A. B.

#### COMMUNICATIONS have been received from—

Dr. CONOLLY; Mr. PAGET; Dr. RIGBY; Dr. MACKENZIE, Glasgow; Mr. WHARTON JONES; Dr. SYMONDS, Clifton; Dr. HARLEY; Dr. DAVIS; Dr. BYRD, Chicago; SECRETARY, GENERAL BOARD OF HEALTH; Mr. TOMES; Dr. CARPENTER; Mr. FIELD; Mr. BAKER BROWN; REGISTRAR GENERAL, Edinburgh; Dr. KENTON; Mr. BUTCHER, Dublin; Dr. FOOTE, Constantinople; Mr. SMITH, Southam; Mr. GRANTHAM, Crayford; Mr. HOOD; Mr. BASTICK; Dr. WHITEHEAD; Mr. BONNER; Mr. HATCHARD; Mr. R. HILL; Dr. DUNN; Mr. JACKSON; Mr. NEAT; Mr. JAMES; Dr. EVERETT; Dr. DYCE; Mr. BARNES; Mr. J. GELLATLY; Mr. J. C. ## APPOINTMENTS FOR THE WEEK.

April 3, Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; Westminster, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Busk, "On the Invertebrata."

#### 5. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopædic Hospital, 3 p.m.  
ENTOMOLOGICAL SOCIETY, 8 p.m.  
EPIDEMIOLOGICAL SOCIETY, 8 p.m.: Dr. Milroy, "On the Sickness and Mortality in the French Army in the East during 1854-6."

#### 6. Tuesday.

Operations at Guy's, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Structure of the Skeletons of Vertebrate Animals."  
PATHOLOGICAL SOCIETY, 8 p.m.

#### 7. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.  
Orthopædic Hospital, 3 p.m.  
HUNTERIAN SOCIETY, 8 p.m.: Dr. Lever, "On Retention and Absorption of the Placenta."  
PHARMACEUTICAL SOCIETY, 8 p.m.

#### 8. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Structure of the Skeletons of Vertebrate Animals."

#### 9. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.  
WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m.; Dr. Alison, "On the Diagnosis of Pulmonary Consumption at its Commencement." A Council Meeting will be held at 7 p.m.

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—  
Lithotomy; trephining tibia. By Mr. Ferguson.

**Carriages, New and Second-hand, of**  
superior style, sterling quality, and finest finish at reasonable rates, for cash, credit, job, or exchange. Circular of prices on application. Credit given when required. Buyers should take carriages on trial, with power to purchase by yearly payments, and thus prove them.  
**OFFORD'S PATENT MEDICAL-MAN'S BROUGHAM MANUFACTORY, 79, WELLS-STREET, OXFORD-STREET.**

## Pepsine.—M. Boudault begs to state

that he cannot be answerable for the purity and strength of any Preparation sold under his name unless obtained from his sole Agent, Mr. PETER SQUIRE, her Majesty's Chemist, 277, Oxford-street, London, to whom all applications respecting it must be addressed.

Second Edition of Boudault on "Pepsine," with Remarks by English Physicians. Edited by W. S. SQUIRE, Ph. D., published by J. Churchill, London, may be also had of the Author, 277, Oxford-street, price Sixpence.

## A New Discovery. — Mr. Howard,

**SURGEON-DENTIST, 52, FLEET-STREET,** has introduced an entirely NEW DESCRIPTION of ARTIFICIAL TEETH, fixed without Springs, Wires, or Ligatures. They so perfectly resemble the newest teeth as not to be distinguished from the original by the closest observer; they will NEVER CHANGE COLOUR or DECAY, and will be found very superior to any teeth ever before used. This method does not require the extraction of roots, or any painful operation, and will give support to and preserve teeth that are loose, and is guaranteed to restore articulation and mastication; and that Mr. Howard's improvements may be within the reach of the most economical, he has fixed his charges at the lowest scale possible. Decayed Teeth rendered sound and useful in mastication.

## Solution Nitrate of Oxide of Glycyl,

used with success in the relief of SPASMS, HEADACHE, NEURALGIA, etc. by A. G. Field, Esq. F.R.C.S.

"I have not yet met with one well-defined case of neuralgic or spasmodic disease in which this medicine has failed to afford relief."

"As a direct sedative to the nervous system, without possessing any stimulating or permanently depressing qualities, without affecting secretion, together with its power of subduing muscular action, it appears to promise to become an invaluable agent in the treatment of a large class of nervous and spasmodic diseases."—Medical Times, March 20, 1858.

This powerful remedy requires the greatest care and exactness in its preparation. That the Profession may assure themselves they are using a preparation of uniform strength, each bottle will bear the signature of the manufacturers, **PERRINS and BARNITT, Operative Chemists, 22, Conduit-st., London, W.**

## Wines from South Africa. — Port,

**SHERRY, etc., TWENTY SHILLINGS PER DOZEN.** These Wines, the produce of a British colony, which has escaped the vine disease (the vintage occurring in February may account for the same), are in consequence wholesome, and are warranted free from acidity and brandy, are admitted by Her Majesty's Customs at half-duty, hence the low prices. A Pint Sample Bottle of each for twenty-four stamps, Bottles included. Packages allowed for when returned.

"We have taken the trouble to try Mr. Denman's wines, and have also submitted them to several of the clergy, and the opinion formed is that they are worthy of being patronized."—Clerical Journal, October 22, 1857.

**EXCELSIOR BRANDY, Pale or Brown, 15s. per gallon, or 30s. per dozen.** Terms—Cash. Country orders must contain a remittance. Cheques to be crossed "Bank of London."

J. L. Denman, Wine and Spirit Importer, 65, Fenchurch-street. Counting-house entrance, first door on the left up Railway-place.

## For Use Medicinally, in all Diseases of

the STOMACH, CHEST, etc., for dressing and deodorizing cancer and all foul wounds, for purifying sick chambers, for embalment of the dead, etc., Mr. JASPER ROGERS'S PATENT CARBONIZED PEAT MOSS. The various kinds of powder and lozenges are prepared solely by the Health of Towns Improvement Company. Sole Wholesale Agent, Joseph G. Thompson, Esq., 2, Adelaide-place, London-bridge, London, E.C., and 6, Donegal-square, Belfast; sold by Mr. W. L. Bird, Pharmaceutical Chemist, 42, Castle-street, East, Oxford-street, W.; Mr. J. Johnson, Chemist, 123, Upper-street, Islington, N., London; Messrs. Bewley and Evans, Dublin; and all respectable Chemists. See extracts from publications on the subject, with the preparations.

## The Best Food for Children, Invalids,

and others.—ROBINSON'S PATENT BARLEY, for making Superior Barley-Water in Fifteen Minutes, has not only obtained the Patronage of Her Majesty and the Royal Family, but has become of general use to every class of the community, and is acknowledged to stand unrivalled as an eminently pure, nutritious, and light food for Infants and Invalids; much approved for making a delicious Custard Pudding, and excellent for thickening Broths or Soups.

ROBINSON'S PATENT GROATS, for more than thirty years, have been held in constant and increasing public estimation, as the purest farinae of the oat, and as the best and most valuable preparation for making a pure and delicate GRUEL, which forms a light and nutritious support for the aged, is a popular recipe for colds and influenza, is of general use in the sick chamber, and, alternately with the Patent Barley, is an excellent Food for Infants and Children.

Prepared only by the Patentees, ROBINSON, BELVILLE, and CO., Purveyors to the Queen, 64, RED LION-STREET, HOLBORN, LONDON.

Sold by all respectable Grocers, Druggists, and others, in town and Country, in Packets, at 6d. and 1s., and in Family Canisters, at 2s., 5s., and 10s. each.

## The Medicated Cod Liver Oils,

comprising  
**OLEUM MORRHUÆ CUM QUINA.**  
**OLEUM MORRHUÆ CUM FERRI IODIDO.**  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

EFFICACIOUS PREPARATION BY  
SAVORY and MOORE, 143, New Bond-street.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS, assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.
6 and 8 oz., any shape, plain, or graduated	8	0 per gross.
3 and 4 oz. ditto ditto	7	6 do.
1 oz. Moulded Phials	4	6 do.
1 oz. ditto	5	6 do.
1 1/2 oz. ditto	6	0 do.
2 oz. ditto	7	0 do.

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

ESTABLISHED 1830.

## M. and R. Jewell beg to express their

thanks for the encouragement they have received from the Medical Profession, and hope for a continuance of their favours at their Medical Glass and Bottle Warehouse, 53, Howland street, Tottenham-court-road, where an extensive Stock is always kept on hand, at the lowest prices. Measures, Stopped Bottles, Pedestal Mortars, etc. etc. Orders punctually attended to. List of prices forwarded post free.

## Surgical Instruments, and every Im-

plement necessary for Surgeons and Druggists, can be had (warranted best quality and moderate prices), retail as well as wholesale, from the Manufacturer, JAMES ARNOLD, 35, WEST SMITHFIELD, St. Bartholomew's Hospital, London.

Single Circular Truss, 2s. 6d.; double ditto, 5s.; on Salmon's Expired Patent, 4s. 6d.; double ditto, 9s.; on Coles's Expired Patent, 5s.; double ditto, 10s.; Cotton Net Suspensory Trusses, from 10d.; Elastic Stocking Net bandage, 4d. per yard; Case of Tooth Instruments, £1; Case of Cupping Instruments, £2 18s. 6d.; Case of Pocket Instruments, £1; Brass Enema Syringe, complete in mahogany case, 10s. and 12s.; Case of Dissecting Instruments, Ivory Handles, 15s.; best Bleeding Lancets, per dozen, 18s.

BROUGHAMS.

## Kinder, M'Naught, and Smith,

MANUFACTURERS, WORCESTER, beg respectfully to invite the attention of professional men to their improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in.	7 1/2 cwt.	5 Guineas.
3 ft. 6 in.	8 1/2 cwt.	95 Guineas.
3 ft. 7 in.	9 cwt.	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hoffmann, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.  
THE MEDICAL TIMES AND GAZETTE.  
THE BRITISH MEDICAL JOURNAL.  
THE MEDICAL CIRCULAR.  
EDINBURGH MEDICAL JOURNAL.  
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, etc.

SOAP-WORKS, CLEBKENWELL, LONDON, E.C.

## Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS at the Warehouse, 2, Upper Copenhagen-street, Barnsbury-road, Islington, London, N.

E. and H. Harris beg to submit the following prices, for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

	s.	d.
6 & 8 oz., any shape, plain or graduated	8s.	per gross.
3 & 4 oz., do.	7s.	6d. do.
1/2 oz. white moulded phials	4s.	6d. do.
1 oz. do.	5s.	6d. do.
1 1/2 oz. do.	6s.	do.
2 oz. do.	7s.	do.

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London. Bankers: Union Bank of London.

## ORIGINAL LECTURES.

A COURSE OF CLINICAL LECTURES  
ON  
DISEASES OF THE KIDNEY.

By GEORGE JOHNSON, M.D. F.R.C.P.

Physician to King's College Hospital.

## LECTURE VIII.—CONCLUSION OF THE COURSE.

We have seen that the chronic desquamative disease of the kidney may pass through all its stages and produce extreme atrophy and contraction of the gland without the occurrence of dropsy. In cases of *contracted* Bright's kidney the existence of dropsy, in any great degree, may be considered as an exception to a general rule; whereas, in cases of chronic Bright's disease with *enlargement* of the kidney, whether the kidney be fat or in a state of so-called waxy degeneration, the presence of dropsy, sooner or later in the course of the disease, is the rule, and its absence the exception. For some time past I have been engaged in making a tabular analysis of a large number of cases of Bright's disease, with a view to ascertain, amongst other points, what is the relative frequency of dropsy in the different classes of cases. My analysis is not yet sufficiently advanced to enable me to give you the exact numbers, but I can tell you with the greatest confidence that, while some cases of large Bright's kidney terminating fatally have been unattended with dropsy at any period of their history; and while dropsy has been present in some cases of contracted kidney, yet the rule is as I have just now stated it to be.

The common occurrence of dropsy in one well-defined class of cases of chronic renal disease, and the comparatively rare occurrence of that symptom in another class of cases, constitutes one of the most obvious and weighty objections to the theory which assumes that Bright's disease is always one and the same disease, and that a large Bright's kidney presents only an early stage of the same morbid process as that which induces atrophy and contraction of the kidney. For if all the contracted Bright's kidneys have passed through a previous stage of enlargement, it is difficult to understand how it happens that nearly all those patients who reach this final stage, should have escaped the dropsy which so commonly troubles those who die in what is assumed to be an earlier stage of the same disease.

Another important difference between the two classes of cases, and one which is closely connected with the relative frequency of dropsy as a symptom of the renal disease, is to be found in the quantity and quality of the urine secreted. Associated with the large Bright's kidney, we generally find a scanty secretion of highly albuminous urine; whereas, the contracted kidneys commonly secrete an abundance of urine of low density, which seldom contains much albumen, and sometimes none at all. Now, it is a generally admitted fact, that, *ceteris paribus*, the risk of dropsy is directly as the drain of albumen, and inversely as the secretion of water by the kidneys. The more scanty the secretion of urine, and the greater the amount of albumen which it contains, the greater is the probability that the patient will become dropsical. I might go on to show you that there is a difference in the morbid anatomy of the kidney in the two forms of disease, which, to a considerable extent, explains the difference in the character and the quantity of the urine; but I wish rather to direct your particular attention to the fact that, as I just now stated, the urine secreted by a wasting Bright's kidney sometimes contains no albumen.

We are so much in the habit of relying upon albuminous impregnation of the urine as a sign of Bright's disease, that the absence of that symptom is very likely to mislead us. Now, the fact is, that, both in the early and in the advanced stages of chronic desquamative disease of the kidney, the urine sometimes contains not a trace of albumen.

This form of renal disease frequently affects the subjects of confirmed and inveterate gout; and if you examine the urine of such patients, you will often find that, after a few hours' rest in a conical glass, it deposits a cloudy sediment, con-

taining the granular casts (Fig. 7, p. 269), which are for the most part composed of disintegrated gland cells from the tubes of the kidney. The appearance of these casts, then, is *pro tanto*, evidence of a destructive process affecting the secreting cells of the kidney; and this evidence of degeneration is often unassociated with albumen in the urine.

In most of the cases to which I am now referring, the renal disease is, probably, in an early stage; but I have met with several instances in which, although the urine contained little or no albumen, yet the kidneys were found, after death, in an advanced stage of degeneration. One case of this kind will serve as an illustration. On the 6th February, 1886, a man named Joseph J., aged 57, came into the out-patient room, and told us that he was a brass-finisher, of temperate habits; that he had once had an attack of gout, and that for several years he had been subject to winter-cough. The cough had been very troublesome for some months past, and he had suffered from dyspnoea and weakness. He had the large barrel-shaped chest which often accompanies emphysema of the lungs, and he presented the physical signs of bronchitis. The heart, pushed down by the enlarged lung, was felt beating in the epigastrium, but its sounds were normal. The ankles were somewhat swollen, and the face, sallow and puffy, was so decidedly suggestive of renal disease, that I requested him to pass some urine, in the confident expectation that I should find it albuminous. To my surprise, however, it contained no trace of albumen. He was too ill to be treated as an out-patient, and I admitted him into No. 4 Ward, where the urine was repeatedly tested for albumen, with a decidedly negative result, except upon one occasion, when it was noted that "the urine contained a small quantity of albumen (?)"—a query being added to signify a doubt as to the fact. While in the Hospital, he frequently vomited a clear acid liquid; and on the evening of the 17th February he was found by the House-Physician in a state of collapse, with great tenderness of the abdomen, indicative of severe peritonitis. He died within twelve hours from this sudden seizure, and on examination it was found that the immediate cause of death had been intense peritonitis, excited by the escape of the contents of the stomach through a perforating ulcer of that viscus. The kidneys were small, the cortical substance was much wasted, and contained several cysts. On microscopic examination there was evidence of advanced and extensive degeneration of the secreting tissue. These appearances are still plainly seen in portions of the kidney, which I have preserved as microscopic specimens.

This case affords as good an illustration as I can give you of advanced renal degeneration, unassociated, except doubtfully upon one occasion, with albumen in the urine. Cases of this kind are by no means of rare occurrence, and therefore, when we have reason to suspect disease of the kidney, we are not at once to conclude that the absence of albumen negatives the idea, but the urine should be submitted to careful microscopic examination. In the case which I just now related to you we neglected to examine the urine microscopically until after the patient's death. We then found that the urine contained in the bladder had in it the granular tube-casts, which are usually indicative of the chronic desquamative form of disease, and which, if we had observed them during the patient's lifetime, would have confirmed us in our suspicion that disease of the kidney formed a part of his ailments. It is probable that the dropsy in this case was chiefly due to the impeded circulation through the lungs, consequent on the emphysema and bronchitis.

I have not yet met with a case of unequivocal chronic desquamative disease of the kidney, in which the urine contained neither tube-casts nor albumen. I have found the urine albuminous without containing tube-casts as in the case of Louisa S., which I related to you in my last lecture; and I have, in several instances, found the granular casts without albumen. As a matter of precaution it is well to bear in mind the possibility that both tube-casts and albumen may for a time be wanting in some cases of the disease in question. In such cases, if there be such, the diagnosis would be very difficult and doubtful.

We have seen that the granular form of tube-cast is generally associated with the chronic wasting form of Bright's disease. I wish now to impress upon you the fact that these granular casts do not necessarily and invariably indicate chronic disease, but that they may occur as the only form of tube-cast in the urine of a patient who has an acute and

curable affection of the kidney. The diagnosis of renal diseases would be much easier than it is if each form of tube-cast were constantly associated with one particular condition of kidney, just as the diagnosis of pulmonary disease would be facilitated if fine crepitation, bronchial breathing, pectoriloquy, etc., were each diagnostic of one special morbid condition of lung; but as this is not the case with the physical signs of either renal or pulmonary disease, it behoves us to give to these subjects the additional care and thought which they require, in order that we may escape being misled.

I have found the granular casts with albumen in the urine of patients suffering from various forms of acute disease, and I have observed that the urine has regained its normal characters during the convalescence. I may mention, as examples, typhus and typhoid fever, pyæmia, erysipelas, and pneumonia. A case which occurred not long since in the Hospital, affords a good illustration of the practical importance of a correct interpretation of these granular casts.

William Morrison, aged 26, a painter, was admitted into No. 4 ward on the 7th August. Like most men of his trade he had drunk pretty freely of beer; and he had suffered several attacks of colic. His present illness began on the 2nd of August with pain in the limbs and in the belly, from which he continued to suffer until the 6th, when he was suddenly seized with giddiness, and fell on the floor immediately after rising from bed in the morning: he quite lost consciousness for a time, but quickly recovered it. In the course of the day he had two or three similar attacks, and on the following day he was admitted under my care. On the morning of the 8th—that is, the day after his admission—he suddenly fell down insensible while at the water-closet; he was immediately carried back to his bed, and for about two minutes he was much convulsed. I happened to enter the ward immediately after the convulsion had ceased. He was still unconscious, his breathing was stertorous, the face very pale and cold, and the pupils were unequal, the left being much smaller than the right. Whatever the disease might be it seemed only too probable that it would be quickly fatal. It occurred to us as a possible solution of the symptoms, that the case was one of advanced Bright's disease with uræmia. Obviously it was important to ascertain the condition of the urine, but none, we were told, had been passed since his admission. A catheter was now introduced, and a few ounces of urine were thus obtained. It was very acid, somewhat high coloured, sp. gr. 1014, it contained a very small quantity of albumen, and on subsequent examination we found in it many granular casts. This being the character of the urine, what was the probable condition of the kidney? The small quantity of albumen in the urine precluded the idea of any of the ordinary forms of acute Bright's disease, and of any form of chronic disease except the chronic desquamative. It seemed by no means improbable that the latter disease had produced contraction of the kidney, and that the brain symptoms were the result of uræmia; but, there was some reason to hope that the kidneys were *not* in an advanced stage of degeneration, for the density of the urine was somewhat higher and the colour decidedly deeper than is usual in the last stage of contracted Bright's kidney. It was at least possible that the albuminous urine and the granular casts might be the result of some zymotic blood-poison; and we felt that the condition of our patient, although sufficiently alarming, was not quite desperate, as it would have been if advanced degeneration of the kidney had certainly been at the root of the symptoms.

I have already told you that when the convulsion had ceased the patient was in a state of extreme exhaustion, which threatened to be fatal. To guard against this tendency we immediately gave him a small quantity of brandy with water, and directed that he should have six ounces of brandy in repeated small doses during the twenty-four hours. A blister was applied to the nape of the neck, and he took two scruples of the compound jalap-powder. This dose had to be twice repeated, and then followed by one of castor oil before the bowels were freely moved.

The progress of the case from day to day was fully and faithfully recorded by my clinical clerk, Mr. Meadows, but my present purpose will be answered by a very brief abstract of the history. When the patient had rallied from the collapse which followed the convulsive seizure, the pulse and respiration were rapid, the former 120 and the latter 44, the tongue was dry, and the skin hot, but no eruption was

seen at any period of the case. We then detected the physical signs of pneumonia affecting the lower lobe of the right lung, and as the inflammation resolved itself, a friction sound over the same part showed that the pleura had been involved in the disease. He remained for some days in a half-conscious, delirious state, but these symptoms gradually passed off, and the pupils became equal. The urine had ceased to be albuminous on the 16th, but the tube-casts were visible for a few days longer. He continued to make steady progress towards convalescence; and when he left the hospital on the 15th September, no trace of disease remained.

With regard to treatment, the only means employed besides those which I have already mentioned, were an occasional turpentine stupe to the chest, and an effervescing saline draught, which he was allowed to take *ad libitum*.

As to the pathology of the disease, I can only suggest that some zymotic blood poison affected simultaneously the brain, the lung, and the kidneys, and so excited the symptoms which were referable to each of those organs.

Bear in mind that my chief object in referring to this case, is to show you that granular tube-casts, very similar to those which are seen in cases of chronic desquamative disease, may occur as a result of some transient blood zymosis.

I have preserved microscopic specimens of the casts which occurred in this patient's urine, so that we can refer to them and compare them with the casts which we may find in any future case of the same kind.

For some time past, as most of you are aware, I have been in the habit of preserving specimens of the urinary sediment in all cases of unusual interest, and I advise you to do the same; you will find that such memoranda of cases of renal disease will afford you most important aid in forming a correct opinion respecting other cases which you may hereafter meet with. With this piece of practical advice I bring the present series of lectures to a close.

## LECTURES

ON

## THE ANATOMY, INJURIES, AND DISEASES OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

### LECTURE III.—Continued.

#### ON INDIRECT FRACTURES OF THE BASE OF THE SKULL.

BUT why are fractures of the base frequently thus limited to such well-defined regions? The answer to this question is to be found in the anatomical disposition of the skull, and in the nature of the accident.

Recall to mind the disposition of the base of the skull with its three fossæ, on different levels, and all clearly mapped out by prominent and well-defined ridges; recall to mind, moreover, that each fossa of the skull has its corresponding part in the vault. Such a disposition of the bones enables us, as I have already mentioned in a former lecture, to divide the skull into three different zones or segments; an anterior zone, formed by the frontal, the upper part of the ethmoid, and the fronto-sphenoid; a middle zone, formed by the parietals, the squamous, and the anterior surface of the petrous portion of the temporals with the greater portion of the basi-sphenoid; and a posterior zone, which is formed by the occipital, the mastoid and the posterior surface of the petrous portions of the temporals, with a small part of the body of the sphenoid.

If the skull be thus divided into three different zones, the fractures stretching from the vault into the base will often be found strictly limited to one of these regions.

Let me briefly mention one or two examples selected from each of these three regions. And first, as to fractures confined to the anterior fossa.

A man, aged 37, fell from a tree while bird-nesting. About the head the only external injuries observed were a fracture of the nasal bones, with extensive bruising of the eyelids and

upper part of the face. The most important injury was a very severe compound fracture of the thigh, from the effects of which he died in twenty-four hours. The frontal bone, just anterior to the crista-galli, presented a slight fissure, which was traced down into the cribriform plate of the æthmoid, and partly into the orbital plate of the frontal. No other injury was observed about the bones of the skull.

A lad, aged 15, fell from a ladder. The only external injury about the head was a superficial scalp-wound, a little above the left brow. He went on well for some days, but inflammation of the cerebral membranes supervened, and he died on the 26th day after the accident. Corresponding to the scalp-wound, which was healed, was a lineary fracture passing perpendicularly into the left orbital plate of the frontal, where two small portions of bone were completely broken off, and driven about two lines down into the orbit.

The following are two cases limited to the middle fossa:—

A man, aged 30, was pitched out of a cab while drunk, and died twenty minutes afterwards. The scalp was slightly bruised over the right parietal eminence. Commencing a little below this spot was a fracture, which passed through the squamous portion of the temporal, reached the great wing of the sphenoid, and ended in the sphenoidal fissure.

A man, aged 25, fell while drunk from the top of an omnibus, and died in a few minutes. In this case the fracture, commencing in the centre of the right parietal, was traced obliquely across the squamous portion of the temporal, and through the great wing of the sphenoid into the body of this bone, at its junction to the æthmoid. Another line of fracture also ran some distance along the anterior surface of the petrous bone, breaking the upper wall of the tympanum.

In the next cases it was the posterior fossa that was involved.

A lad, aged 13, was pitched off a donkey, and fell on to the back of his head. He went on well for some days, but subsequently died of inflammation of the membranes of the brain, and extensive suppurative around the left sacro-iliac synchondrosis. The only injury about the bones of the skull was a narrow fissure, which began at the lateral sinus, and passed perpendicularly into the foramen magnum.

A man, aged 40, while drunk, was knocked down in the street. He died thirteen days after the accident, of diffuse inflammation of the membranes. Lineary fractures were traced from the torcular Herophili in various directions; one branch passed upwards into the right cerebral fossa; another downwards into the right cerebellar fossa, and a third into the foramen magnum; besides which there were two or three smaller branches, but none of these fractures passed beyond the occipital bone.

In the above cases we have clear evidence that a fracture beginning at the seat of the blow on the vault does not, in many instances, spread beyond the corresponding bones of the base. I might greatly have multiplied examples such as these, for I have by me notes of no less than 25 cases of fractured base thus limited. Let me, however, state that in 5 of these cases the line of fracture was traced from the forehead into the bones at the base of the anterior zone, and into these alone; from the parietals or temporals in 14 cases the fracture was found to pass into the corresponding bones at the base; and in 6 cases the line of fracture passed from the occipital into the posterior segment only.

When the injury has been of a severer nature than it was in the cases which I have just mentioned, it frequently happens that the line of fracture starting from the vault spreads into two of the fossæ at the base at the same time. This, however, is easily accounted for, when we come to examine the position of the middle fossa, the bones of which are not only wedged in between, but also firmly articulated with, the bones of the other fossæ. Thus situated, the middle fossa either receives or transmits the injury; and the fracture in these cases generally runs obliquely from one fossa into the other; or else, coursing along the boundaries of the zones, in the neighbourhood of the sutures, which may be widely separated, the fracture passes into both fossæ at once.

And the fossæ thus implicated may be either the middle and anterior, or the middle and posterior ones. Thus, in 29 cases, where the line of fracture occupied two fossæ at the same time, I found it in fourteen cases in the middle and anterior fossæ, and in fifteen cases it was in the middle and posterior ones.

In the following case the fracture spread from the forehead

both into the anterior and into the middle fossæ at the same time.

A man, aged 45, fell from a ladder on to his head, a distance of about forty-five feet. The only external appearances were an extensive bruising of the eyelids, with protrusion of the eyeball, from blood in the orbit. There was also some bleeding from the nose, and a large quantity of blood was subsequently brought up. He died seven hours after the accident. Extravasated blood was found over both frontal eminences, and in the right temporal muscle. The right side of the frontal bone was extensively broken; a line of fracture was traced, running obliquely across the roof of the orbit into the æthmoid, and from thence into the front part of the body of the sphenoid, and through its left wings into the anterior surface of the left petrous bone, where it ended, breaking into the tympanic cavity, but not rupturing the membrane.

The next is a case in which the line of injury was traced from the parietal bone both into the middle and into the anterior fossa.

A lad, aged 14, was thrown from a horse. He was picked up in a state of perfect insensibility, the only outward appearance being a bruise over the right eye, and protrusion of the eyeball from blood in the orbit. He died two hours after the accident. Blood was found extensively extravasated over the right side of the head, and in the substance of the temporal muscle. Towards the back part of the right parietal, and about two inches from the temporal bone, was a comminuted fracture with some slight depression. From this spot, skirting the squamous suture, a line of fracture was traced into the coronal suture, which it followed, and ultimately divided into two branches, one of which, coursing onwards, reached the orbital plate of the frontal, and the other, passing downwards, stretched into the body of the sphenoid, and ended in the great wing on its left side.

And now I will mention a case in which the injury passed from the back of the head into the posterior and middle fossæ at the base.

A man fell on to the back part of his head against a stone pavement, producing a small scalp wound, not exposing the bone, on the right side of the occipital, near the lambdoid suture. He died of diffuse inflammation of the membranes eight days after the accident. A line of fracture was traced from the seat of the blow, in the neighbourhood of the right lambdoid suture, obliquely through the occipital, to the left side of the foramen magnum, which it skirted, and then proceeding through the lateral sinus, it reached the petrous portion of the temporal, which it cut across, and then passed along the anterior surface of the bone, towards the inner opening of the carotid canal, where it ended.

But, whenever the accident is of a very severe nature, the fracture spreading from the vault into the base, may be much more extensive than any we have hitherto seen. In falls from very great heights, or in blows of a very severe character, all three fossæ may be involved at the same time. In these cases the fracture is generally accompanied by extensive separation of the sutures.

A man fell from a cart loaded with hay, and pitched directly on to his head. He was picked up bleeding profusely from a large scalp-wound at the top of the head, was perfectly insensible, never rallied, and died in a few hours. In addition to the wound, the scalp at the top of the head was extensively infiltrated with blood. The coronal suture was separated in its whole length, and from the ends of this suture fractures were traced into the upper walls of both orbits, and through both great wings of the sphenoid right across the basilar process, thus completely dividing the skull into two halves perfectly moveable upon each other. There was also a perpendicular fracture running along the basilar process into the foramen magnum. The petrous bone was not in the least injured.

A man, aged 27, fell from a scaffold thirty feet high. The only external appearances observed about the head were some large bruises over the forehead and eyelids, with profuse bleeding from the nostrils. He remained perfectly insensible, and died four days after the accident. The scalp of the forehead was extensively infiltrated with blood. A fracture, commencing an inch above the middle of the left superciliary ridge, was traced through the left orbital plate of the frontal into the æthmoid, and thence into the body of the sphenoid, which was broken into several fragments, widely separated

from each other. Passing through the cavernous sinus, the fracture continued its course into the left great wing, and into the petrous bone, which was also broken in two places. One line of fracture then ran into the occipital, through the lateral sinus, and along the foramen magnum into the occipital sinus. The fracture around the foramen magnum was comminuted, and the fragments displaced upwards.

But injuries such as these, in which all three fossæ at the base are implicated at the same time, occur much more rarely than those in which the fracture is less extensive. In fact, of this class of cases I found only ten instances.

Within a period of ten years there were then 25 cases in which the line of fracture was strictly limited to one of the three fossæ at the base; there were 29 cases in which two fossæ were involved at the same time; and only ten cases in which the injury had spread into all the three fossæ at once.

Let us, however, especially bear in mind that the middle fossa, either by itself or in combination with the other fossæ, is the region in which fractures most frequently occur. If you cast a glance over the number of cases of fractured base to which I have alluded, you will find that out of the 64 cases the bones of the middle fossa were broken in no less than 53 cases.

In the severer forms of injury we may sometimes find, in various parts of the base, some small circumscribed fractures in addition to, and having no connexion with, the main line of fracture. The roof of the orbit is sometimes thus broken independently of, and away from, the line of the principal fracture. Such were the appearances in a case reported by Mr. John Adams (a). "There was a fracture traversing the left side of the occipital and petrous portion of the temporal, and, in addition to this, a circular portion of bone, of about an inch in diameter, was broken from the centre of the right orbital process of the frontal bone, and driven into the frontal sinus, which was unusually large. No bruise, or any trace of direct violence, was detected externally in the neighbourhood of the injury of the frontal."

And so, too, may we find the posterior clinoid processes chipped off as it were, although the line of fracture does not pass through this part of the bone. Of this I have seen two or three cases.

And now, let me draw your attention to the signs or symptoms by which we are to recognise these fractures of the base of the skull.

I at once pass over all the numerous symptoms so much dwelt upon in olden times, experience having proved that such symptoms are not, in any single instance, to be depended upon.

Neither can we make use of the absence, or the presence of cerebral symptoms for the purpose which we have in view. Cerebral symptoms cannot serve as a guide to fractures of the base. On the one hand you will meet with cases in which the brain is extensively bruised and lacerated, without any injury of the bones; and, on the other hand, you will now and then find cases in which most extensive fractures have existed about the base, and that, too, without a trace of injury about the brain.

In one instance, both orbital plates of the frontal, the ethmoid, and the sphenoid were extensively broken, the latter so much so that its body was reduced into fragments. The parietal was also broken at its back part, and the occipital presented an extensive fissure running right through the foramen magnum, and the right petro-occipital suture was widely open. And all this without a trace of injury about the brain.

In another instance, that of a child, where there was a distinct history of two different accidents, at an interval of a week each, the left parietal bone was broken, perpendicularly nearly in its whole length, with a small circumscribed extravasation of blood underneath the pericranium, evidently of some standing; and, on the right side of the head, there was a more recent fracture, which, beginning at the lower border of the parietal, passed through the great wing of the sphenoid, and ended in the petrous bone, at the foramen auditivum internum. No trace of injury about the brain.

In a third instance, a fracture, commencing at the external angular process of the right frontal, passed through the orbital plate into the ethmoid; the fracture also extended from the lesser wing of the sphenoid, through the body of this bone, and into its left great wing, and ended at the petrous bone. No trace of injury about the brain.

(a) Medical Gazette, vol. xxii. p. 564.

To what symptoms, then, are we to trust as indicative of the existence of a fractured base of the skull?

The only symptoms that can be depended upon are connected, either with an escape of some of the contents of the skull, or with an injury done to the nerves as they are emerging from the skull.

The contents of the skull which escape in a fracture of the base may be blood, watery fluid, or brain substance.

The escape of a watery fluid, and that of brain substance, I must leave for further consideration, as it is my intention to dwell at length upon these subjects in the following lectures. Neither shall I at present touch upon the injury of the nerves at the base. There remains, then, the escape of blood.

But, for this escape of blood to take place, the line of fracture must run in certain directions; it must, in its course involve some of the large vascular channels lying at the base of the skull, and it must open a road through which the blood can get out of the skull, into some part where its escape may be visible.

Should it so happen, however, that the injury does not produce effects such as these, we may have a very extensive and complicated fracture of the base, the existence of which will not be revealed until the examination of the body takes place. Hence the reason why we find some Surgeons still dwelling upon the great uncertainty as to the diagnosis of fractures of this part of the skull. Let us freely admit that this uncertainty does, and must necessarily exist in many cases, still there will remain a large number of instances in which blood issuing from its natural channels, will, under certain conditions, become a diagnostic sign of great value, so much so, indeed, that we may with due care, safely pronounce as to the existence of a fracture.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

### NOTES OF

## PRACTICE AMONG THE OUT-PATIENTS OF ST. BARTHOLOMEW'S HOSPITAL.

By JAMES PAGET, F.R.S.

Assistant-Surgeon to the Hospital.

### NO. IV.—ON SOME AFFECTIONS OF THE URINARY BLADDER AND URETHRA.

I do not profess in any of these notes to record discoveries, or tell things which others do not know, but to relate such facts as, though known to many, are yet not enough known, and to recommend some modes of practice which many follow, and which should be followed by many more.

*Diseases of children imitating the symptoms of vesical calculus.*—A large majority of the children who, when brought to the Out-patients' room, are suspected of having calculus, have none. The imitation of the symptoms is sometimes so exact, that only very careful sounding can persuade one that no calculus is present. In other cases the imitation is less exact, yet sufficient to make sounding necessary.

The diseases that may be thus deceptive are various. The most frequent are the following:—

1. Phymosis, with contracted preputial orifice.
2. Nervous affections of the bladder, either with neuralgia, or with muscular irritability, or with both.
3. Similar affections dependent on disorder of the urine, or ascariæ, or other distant sources of irritation.
4. Morbid growths in the bladder.
5. Tuberculous disease of the same.

Phymosis is a frequent cause of symptoms like those of stone, especially when the prepuce is not only long, but very narrow at its orifice. And it may give rise not to these symptoms alone, but to muscular hypertrophy of the walls of the bladder, dilatation of the ureters and kidneys, and other of the most serious consequences of urinary obstruction. In two young children, I believe that abnormal opening of the urachus at the umbilicus was the consequence of phymosis; for

in one this defect was cured, and in the other relieved, by circumcision.

I need not say that phymosis and calculus may coincide. But the rule that these cases dictate is, that if signs of calculus exist, in a boy with phymosis, and no calculus can be detected, the phymosis should be cured at once. If no advantage be hence derived, some of the other probable causes of the symptoms may be again looked for.

The neuralgia and muscular irritability of the bladder, may, in most respects, be studied better in adults than in children. But it has been best observed in children, that irritable bladders become hypertrophied; and the likeness of this hypertrophy to that of bladders which have long acted against mechanical obstruction, makes it probable that, in these cases, though no cause of obstruction may appear after death, one existed during life. Such an obstruction may arise in discordant actions of the muscles of the bladder and urethra; and I believe that a close resemblance may be traced between many of these cases of irritable urinary organs, and the cases of common stammering. Just as stammering is evidently due, in great measure, to want of consent between the glottis and the expiratory muscles,—the glottis keeping close, or unsteadily opening and closing, during the intended expiration; so, in these stammering bladders (as they might be called) there is a want of consent between the expulsive and the permissive muscles, the latter not quietly relaxing, while the former are acting. Whoever will inquire closely will find that the influence of the mind, and of mental associations, and of interference with the general health, is in both disorders similar; and that the remedies for certain cases of irritable bladder must include, or chiefly consist in, such as are appropriate for vocal stammering. Moreover, in children and adults alike, the remedy of this state is always the more difficult, the more the troubles are of purely nervous origin, and independent of local irritation.

The most frequent extrinsic local sources of irritation of the bladder are ascariæ and morbid conditions of the urine. Their cure will commonly remove all symptoms of disturbance in the bladder.

Morbid growths are so rare in the bladders of children, that they had better not be suspected till the absence of all other probable causes of the symptoms of calculus has been proved. But how closely such growths may simulate those symptoms, and how difficult their diagnosis may be, is well illustrated in the cases of polyp of the bladder related by Mr. Cresse (a) and Mr. Savory. (b)

Far more numerous are tuberculous diseases of the urinary organs, and there are none that in children or, more rarely, in adults, may so closely imitate the symptoms of a calculus in an inflamed and ulcerated bladder. The main things to look for in the diagnosis, when a calculus cannot be detected, are the coincident tuberculous diseases of other parts, especially of the kidneys, testicles, and vasa deferentia, and, in adults, of the prostate and seminal vesicles. For tuberculous disease of the bladder alone is very rare, and equally so is the coincidence of calculus with persistent disease of any of the genital organs except the prostate.

All these diseases of children imitating the signs of calculus are more frequent before than after eight years of age. And even those which are not connected with the urethra are more common in boys than in girls; an evidence that the greater frequency of the disease of the male bladder is not to be wholly ascribed to the troubles into which it is led by diseases of the urethra and other sexual organs.

**Accumulation of Urine.**—Few diseases are likely to be overlooked for want of names, and, generally, medical nomenclature might be made clearer by decrease, rather than by increase, of its terms. But the state that I would call "accumulation of urine," though well described by Hey, and well known to many surgeons, is yet, for want of a name of its own, unknown to many, and confounded by many with retention of urine.

A patient, unconscious of any disease in the bladder or urethra, finds himself becoming gradually more annoyed with fulness of the lower part of the abdomen, or with pain in the bladder, or too frequent action of it, or occasional incontinence of urine in the night. He is sure that he passes his full

quantity of urine daily, and passes it with nearly full force, and little or no difficulty; and retains it easily, except, perhaps, at night; and yet we find the bladder distended. Then, if the bladder be emptied with the catheter, the power of passing urine remains apparently good. It appears to the patient, perhaps, nearly as strong and as complete as ever: but it is not complete: the bladder never quite empties itself, and each day more and more urine accumulates, till it is again as much distended as it was before.

I have known such a state to be the first overt sign of paraplegia; but much more frequently it portends nothing of the kind, and is an entirely local disorder. A case may best illustrate it.

An old man came, on his way to work. He said he thought his bladder must be full, and he had sensations of discomfort in and about it, and his urine-stream was rather less strong than usual; but he believed that he passed as much urine as was his custom. I found the bladder distended, and drew off sixty ounces of urine. Three days later, though he had passed, he said, large quantities, sixty ounces had again accumulated; in four days more, fifty ounces, with no discomfort, and scarcely any other sign of trouble in the bladder. And thus the case went on, the accumulations gradually decreasing, till they were not more than thirty ounces in a week, and then some twenty or thirty ounces in a fortnight. At last, after about three months, the bladder recovered the power of completely emptying itself.

This case may be taken as a fair specimen of "accumulation of urine." The disease appears to be of the same kind with the fecal accumulations which one meets with in persons whose colon or rectum, without being paralysed, is at some part feeble, and who, passing feces daily, are unaware of the masses that day by day are accumulating in them. I think that a similar condition sometimes occurs in the stomach; and it may be impossible to explain the exact state of any of the organs thus able to act, yet not able to act fully. The muscular fibres are not paralysed; for to some extent, or for some time, they act well enough; but, in action, they seem to become prematurely weary, and thus, as they gradually contract less and less, they permit accumulation, till they may be paralysed by excessive elongation, or relieve themselves with some unnatural force.

Cases of accumulation of urine often show how much the secretion of urine is hindered by fulness of the urinary passages. We may guess at the amount of this hindrance from the quantities of urine that are secreted after the accumulation is withdrawn (and similar occurrences may be sometimes noted after the relief of a retention). One day I drew off eighty ounces of accumulated urine from a gentleman's bladder, and in the several days following there were secreted, and either evacuated or drawn off, 80, 75, 68, 70, 65, 65 ounces, varying in specific gravity from 1014 to 1018; and on each day in the next week about sixty ounces, of similar sp. gr. After this, the daily secretion fell to about fifty ounces, his ordinary average.

In the management of this disease, the bladder should be emptied daily, or as often as the accumulation amounts to more than twenty ounces. Generally, tonic treatment is useful: especially, I think, the sesquichloride of iron, in doses of forty or more more minims, does good. I think, also, that strychnine is useful; and, if the patients can bear it, cold sponging over the pubes and perineum should always be employed.

**Strictures of the Urethra.**—One of the best things about strictures to be learnt in an out-patient's-room is the value of medical treatment, and of rules of living, in alleviating the occasional urgencies of the disease, and enabling the patients to live in comfort and without catheters. Many good writers have urged the value of medical treatment in diseases of the bladder and urethra; but their advice is, in Hospital-practice, too often disregarded; and herein is one of the reasons, why there are no diseases in which so much better results are obtained in private practice than in that of Hospitals.

A great majority of the out-patients with stricture come for treatment only when they are worse than usual; and this worseness is generally due to intemperance, disordered digestion, cold, venereal excess, or unusual poverty. Of course every patient ascribes all his troubles to the stricture alone, although before it was thus aggravated, he had tolerated it for months or years. And if one is induced to pass an instrument at once, mischief is likely to be done; for the tissues a

(a) *Treatise on the Urinary Calculus*, pt. xx. fig. 2.

(b) *Medical Times and Gazette*, 1862.

and about the stricture are probably inflamed, ready to bleed, or to be torn, or to become more inflamed, and more changed in texture. As a general rule, therefore, it is best never to try to pass an instrument for a stricture, on the first coming of the patient, unless he have an urgent retention of urine. The disorder to be treated is not mere stricture, but that condition (whatever it be) which aggravates the stricture; and the first object should be to bring back the stricture to the state in which the patient could tolerate it.

Generally, the aggravation seems to be due to a congestion, or inflammatory state, of the stricture alone or with the whole urinary tract. And how slight and transitory a change of this kind may suffice to make a stricture scarcely permeable, may be estimated from the slowness of the swelling of mucous membrane which, in common coryza, will for a time completely hinder breathing through one of the nostrils.

Many of the out-patients who thus come with strictures aggravated complain of pain in the loins. They have headache, a furred tongue, and other signs of (I suppose) congested or inflamed kidneys. All these (unless there be something evidently contra-indicative) should be cupped on the loins. Whether such signs are present or not, the bladder is generally irritable, and the urine is high-coloured and scanty, smells strongly, and feels hot as it passes through the urethra. Alkaline and saline purgatives suit these conditions; and a good formula is, "Potassæ bicarbonatis ʒss., magnesiæ sulphatis ʒj., potassæ nitratis, gr. x. ter die." These should be given in diluted solution, and chloric or nitrous ether, or opium, may be added. A grain of calomel and a grain of opium should be given every night for three nights; or, if the patient be well-fed and gluttonous, ten grains of calomel should be allowed to act before any other medicine is given.

All patients thus suffering are relieved by warm baths. Their diet should be strictly ordered, and, as a general rule, all strong drinks should be forbidden; for the poor have none that are not injurious in such cases as these.

The cases of stricture that should be thus treated make up, I think, about nine-tenths of those that come to out-patients' rooms; and the general result of such medical treatment is, that within a month, or often within a week, the patient reports himself "well," or "much better," or "as well as he has been for years past." The surgical treatment of the stricture may now be safely undertaken; but, generally, the patient thus far relieved is content; and he may be so, if he will observe prudent rules of living. I believe that permanent good is very seldom done by the instrumental treatment of "tolerable" strictures in out-patients; and I am sure it is an error to regard stricture as a disease which has a natural tendency to increase. Left alone, and with well-managed general health, an urethral stricture, if not extremely narrow, will remain unchanged, or become gradually less. Many prudently living men can testify this,—men who had strictures "years ago," which now never trouble them, though they never pass instruments. On the other hand, no instrumental treatment, unless it be the perineal section, will prevent the increase of strictures in those who will not live prudently.

**Retention of Urine.**—What has been said about the management of strictures may apply to the greater part of the cases of retention of urine connected with stricture. There should be no long, or various, or forcible, attempt to pass catheters. Even if the bladder is thus emptied, the patient is most likely to come to the Hospital again in the evening, or next day, with renewed and worse retention, the stricture aggravated by the swelling that follows the passing of the instrument. In this way, success with the catheter is often as mischievous as failure.

It is a good rule, in any such case of retention, to desist from catheterism as soon as blood flows in more than a few drops. Such bleeding implies either congestion of the urethra, which proper treatment will remedy, or else a wrong route taken by the instrument.

The best plan is to admit the patient, if possible; for the things to be done in cases of bad retention are such as few of the poor can manage. The patient should have a warm bath and a warm bed, and, generally, opiate enemata, or chloroform, or local depletion, or, in some cases, the sesquichloride of iron. The time that may be spent in using these things must vary according to many circumstances, such as the duration of the retention, the tension of the bladder, the sufferings and general illness of the patient. But the cases

are very few in which it is necessary to perform any operation in less than twelve hours from the admission of the patient; and, on the other hand, if he be not relieved without operation in less than twenty-four hours it will, generally, be unwise to wait longer.

## ON THE "SQUATTING" UTERUS.

By EDWARD RIGBY, M.D. F.R.C.P.

Late Senior Physician to the General Lying-in Hospital, &c.

Mrs. S., aged 27, pale, hollow-cheeked, emaciated; never pregnant.

Feb. 17, 1857.—Constant pain above the symphysis pubis and left groin, sometimes sharp, increased by standing, constipation, and latterly by the catamenial periods; much puriform discharge. Pulse feeble. Tongue very pale and sulcated. Evacuations light and offensive. Catamenia have become more profuse: the previous period lasted fourteen days: has had night perspirations until lately.

*Exam. per vaginam.*—Upper aperture of pelvis filled by a large globular uterus, which is acutely tender; there is no cervix, but merely a round orifice to mark the os uteri, which is soft and very tender. On passing the sound, the shape of the uterus alters and becomes pyriform; there is now a taper cervix, which, as well as the os uteri, is no longer tender to the touch.

℞. Pil. hydrarg., ext. hyosc. ā gr. v. alt. noct.; acidi hydrochlor. dil., acidi nitrici dil. āā ʒi.; liq. taraxaci, ʒi., infusi cinchonæ oblongifoliæ, ʒvii. M.—Ft. mist.; sumat cochl. magna ii. bis terve die, ante cibum.

℞. Plumbi diacet., extr. conii, āā gr. viii., pulv. acaciæ, ʒss. M.—Ft. suppositorium ori uteri h.s. apponend.

Let her dissolve a desertspoonful of common salt in a pint of water, soak six towels in it, and hang them up to dry; let her use one of these towels every morning after washing.

March 13.—Writes that she is better, but still suffers a good deal from bearing-down pain, and pain in her hips; during the last few days she has suffered pain in the vicinity of the anus, so that she could not sit with any comfort; there has been severe menorrhagia, and she has now profuse leucorrhœa.

Rep. pilulæ just before the next period. Rep. mist. cinchonæ, decoct. quercus c. alumine pro lotionē.

April 7.—Suffered much pain at the last period, which came at the fortnight, she feels weak in consequence; there was not much pain previously; it has been chiefly since the period began, which has now lasted ten days. The leucorrhœa was diminished by the lotion; but she still has the same uterine pain, which is at times severe, with pain on sitting down; she has also pain in the left groin: until this attack she thought she was gaining strength.

Let her attend to the state of the bowels, and lie down during the period. Rep. mist. cinchonæ. ℞. Acidi gallici, ʒi., ext. conii, gr. x., pulv. acaciæ, ʒss. M.—Ft. suppositorium ori uteri o. n. applicandum.

May 8th.—Another period is nearly over. It commenced two days beyond the fortnight. For nearly two days before the discharge appeared she was in such severe suffering as to prevent her rising from her bed. The pain continued unabated for a few days after. "It was most severe behind, with a dreadful bearing down." The bowels are sufficiently open, and more healthy; but defecation has caused "intense pain during this period." She is inclined to perspire. Leucorrhœa "as bad as ever;" is very feeble, and "cannot sit up comfortably." Rep. mistura cinchonæ. ℞. Ferri sulph. gr. xvi., acidi sulph. dil. ʒj., magnesiæ sulph. ʒj., syrupi rhæados, ʒss., aquæ menthæ pip. ʒvijs., M.—Ft. mist.; sumat cochl. magna ij. primo mane. Let her take this medicine every morning after the half-way time.

June 20th.—Is much better. "The period came on at the month, and without any pain beforehand," nor had she any of "that dreadful pain behind," but only the bearing down pain. The period lasted only four days, and she has felt quite well since. She has not been so free from leucorrhœa for years. Appetite much improved—"always hungry." Bowels regular without medicine, and moved without pain. Rep. mist. cinchonæ.

July 30.—Has continued perfectly well until a few days ago, when she had a slight return of bearing down pain.

Thinks that she requires a blue pill every week, which relieves the pain. Bowels regular, but the passage of feces occasionally gives pain. Feels stronger than she has done for a long time.

I had seen this patient in 1849, just after her marriage, when suffering from severe vaginal and vesical irritation, which was relieved by appropriate remedies. I saw her again in 1851. She was very feeble. There was much gastric derangement. The os uteri was low in the pelvis, but otherwise natural; the cervix hard and painful. She had constant leucorrhœa with lancinating pains. I ordered leeches to the cervix, to be followed by suppositories of plumbi diacet. c. extr. conii, and put her upon an alterative and tonic course of treatment; she improved considerably, and I did not see her again. I have now very little doubt but that she was then suffering from a similar condition of uterus to that described in her present case; the different remedies which were used appeared to afford her only a temporary relief, and nearly the whole period which elapsed to when I again saw her in 1857 was passed in ill health and much suffering, the effects of which were but too plainly stamped on her sickly and emaciated features. In addition to the constant drain of profuse leucorrhœa, menorrhagia had lately come on, and was gradually increasing; night perspirations had appeared, and her general state betokened an alarming degree of prostration.

The characters of the "squatting uterus" (as I have called it for want of a better name) were well marked in this case; the hard, globular, and painful uterus nearly filled up the superior pelvic aperture, the cervix was entirely lost in the swollen condition of the organ. On passing the uterine sound and raising the fundus, the change was not less remarkable than instantaneous; the body of the uterus resumed its natural pyriform shape; a soft taper cervix could now be felt, and bore the pressure of the finger without pain. Her health improved under the use of the infusion of red bark and nitro-muriatic acid, but the next period was of a menorrhagic character, and was followed by profuse leucorrhœa, which was considerably diminished by the injection of decoct. quercus c. alumine. The next period (May) came on after an interval of only sixteen days, preceded and attended by intense suffering of an entirely different character to what she had felt before; it was evidently of an ovarian character, and could I have had an opportunity of examining I should have doubtless found the left ovary lower than usual, much swollen, and intensely tender. The peculiarly agonising character of the pain, extending from the side of the pelvis backward, aggravated to a most intolerable degree by the painful bearing down during the passage of feces, leave little doubt as to the source of her sufferings. The connexion of these attacks of ovarian pain with the catamenial period are pretty good evidence that the ovary was not inflamed, but we may infer from the relaxed condition of the uterus and descent of its fundus, that the left ovary was lower in the pelvis than is natural, and that during the engorgement, which it undergoes at a catamenial period, it had been pressed down, and probably more or less strangulated during the passage of feces from the sigmoid flexure of the colon into the rectum. Still, however, the indications of treatment were the same, viz. to keep the bowels well emptied, and to improve the strength as much as possible. The morning laxative of ferri and magnesia sulph. was given every day from the half-way time up to and through the period; the bark mixture was continued steadily. A manifested improvement was the result as shown in the report of June 20th, and I trust that she has since been adhering to this plan of treatment until her health was fully established.

Berkeley-square.

## THE CHEMISTRY OF CAUSTICS.

By WILLIAM BASTICK, M.P.S.

Of all the applications of chemistry to the sciences of medicine and surgery, there is not one which has been so little studied or written upon as the Chemistry of Caustics. Having recently had my attention called to this fact, while making some investigations into the nature of caustics, and especially their mode of action, I propose to lay briefly before those interested in this subject the conclusions arrived at, however fallacious the labours of future and abler investigators may prove them to be.

It seems to me that caustics, with reference to their action, may be divided into two great classes, namely, one which comprises those which merely kill or destroy the vitality of the living tissue; and the other, which includes those which not only destroy the vitality of the living tissue, but decompose or dissolve the tissue whether dead or living.

As examples of the former class, may be enumerated chloride of zinc, sulphates of copper and zinc, bichloride of mercury, etc.; and as examples of the latter class, may be mentioned caustic potash, nitrate of silver, manganese cum potassa, chromic acid, etc.

Another distinctive feature of these two classes is, that while the latter destroys and decomposes the living or dead tissue, the former, having killed the living tissue, acts afterwards as a powerful antiseptic or preservative of it.

It is not within my province to point out to those extensively employing caustics, to whom these facts may be new, the importance of bearing in mind this distinctive feature between the two classes of caustics, when selecting the description of caustic to be employed in any given case.

Although caustics may be conveniently divided in the manner described into two principal classes, these classes can be further subdivided into many others, because the mode of action is frequently distinct in each individual case, whatever the final result may be on the living tissue.

To illustrate this point, the modes of action of caustic, potash, and chromic acid may be cited. When the living tissue is placed in contact with caustic potash, the destruction of its vitality ensues by the potash dissolving its albuminous and fibrinous components. In fact, acting in the manner described by chemists for obtaining the various protein substances from organic matter. Of course I only allude to the leading features of the action of caustics in this instance as well as in others. When the same tissue is treated, chromic acid, instead of obtaining a solution of the protein compounds of the tissue, and thus destroying its organized structure, the tissue is destroyed by a slow process of combustion; or, in other words, it is oxidized at the expense of the oxygen of chromic acid, by reason of the facility with which that acid parts with its abundant oxygen when in contact with organic bodies. The manganese with potash acts in a similar way as a caustic to chromic acid, but in consequence of the permanent and manganic acids which it contains being in combination with the base potash, its action is more controllable and persistent. It may be not here out of place to mention what appears to me to be a practical advantage that the destructive caustics, if I may so term them, possess over the conservative ones. In doing so I beg to state, once for all, that I offer my opinions on such points with great diffidence, knowing that chemistry is not medicine or surgery, but only one of their instruments. The practical advantage is this:—When the Surgeon desires the removal of a diseased tissue by caustics, if he uses a conservative caustic he kills the tissue, but has to effect its separation by a further process of suppuration, etc., whereas if he employs a destructive caustic, the two processes are in simultaneous action, and the desired result is consequently more speedily accomplished.

Nitrate of silver is essentially an oxidizing caustic, but its action is much slower than that of chromic acid or manganese with potassa, from the circumstances that it does not so readily part with its oxygen, and it forms an insoluble compound with organic structures which acts as a preventive to its continuous powers as a caustic, by forming a sort of impermeable coating on the tissue to be removed. I am aware that this action is an advantage where hæmorrhage is to be feared.

The exsiccated sulphate of zinc and copper, when employed as caustics, act like chloride of zinc by their powerful affinity for water. But when the vis vitæ is destroyed by such affinity, their further action is that of strong antiseptics, thereby greatly, if not entirely, retarding the natural disruption of tissues which have ceased to possess vitality. Bichloride of mercury, and in fact, all mercurial caustics possess a conservative action by their strong affinity for the albuminous components of organic structures with which they form compounds of definite character.

Nitric and sulphuric acids belong to the class of destructive caustics; the action of the former is that of the oxidation of the tissues, while the latter owes its power as a caustic to its power of extracting the elements of water from organized bodies, behaving like the exsiccated salts previously mentioned,

with which it is sometimes judiciously combined to prevent the spreading of the acid beyond the parts to be destroyed by reason of its fluidity when uncombined.

Chloride of gold has been extensively employed generally in combination with other caustics in some of the Continental Hospitals. When placed in contact with organic matter, this salt is reduced to a metallic state similar to the action of nitrate of silver; but as far as my experience goes, it is inferior as a caustic to the silver salt, because of the large quantity of oxidizing material which is set free when the organic matter is treated with nitrate of silver. Among the conservative caustics, arsenic and its compounds will find its proper class; for although arsenic is poisonous to living tissue, it is a powerful antiseptic agent. It forms no combinations with dead or living tissue, and only a feeble one with albuminous matter; and from this cause it must be regarded in a chemical point of view as a very inefficient caustic.

Chlorides of antimony and iron, which have been used as caustics, exhibit a mode of action similar to chloride of zinc. The very feeble action of the latter must in some cases be its principal recommendation.

It will be evident from the previous statements that chemistry will supply us with an indefinite number of caustics; for it is clear that whatever decomposes or combines with living tissue sufficiently to kill, it is, to all intents and purposes, a caustic. It is also equally manifest that, while it is the essential condition of every substance professing to be a caustic, it should kill the living tissue, it by no means follows that all caustics performing this condition should destroy or dissolve away, as it were, the tissue when no longer possessing life, for this latter property belongs to a distinct class of caustics.

I am aware that I have not noticed the so-called irritant action of caustics; but in explanation I reply that the consideration of this action is foreign to the purpose of this communication, and moreover is a subject not within the province of the chemist.

Brook-street, Bond-street.

## THE LONDON PRACTICE OF MEDICINE AND SURGERY.

### GUY'S HOSPITAL.

#### OPENING OF THE STOMACH FOR THE RELIEF OF STARVATION FROM MALIGNANT STRICTURE OF THE CESOPHAGUS.

(Case under the care of Dr. HABERSHON and Mr. COOPER FORSTER.  
[Communicated by Dr. HABERSHON.]

THERE are many operations which are undertaken to relieve suffering and to prolong life, without the prospect of cure, and the one performed in the following case was of that kind. Walter H—, aged 47, was admitted under Dr. Habershon's care into Guy's in October 1857. He had been suffering from chronic bronchitis for about fifteen years, but at the time of admission had severe pain in his throat, greatly increased on coughing and by swallowing. On examination, the eye could not at that time detect disease in the throat. In the chest there was great feebleness of the respiratory murmur at the apices, prolonged expiratory murmur, with slight sibilant râles, were generally audible; there was increased resonance on percussion. The dysphagia gradually increased, and emaciation steadily progressed; coughing produced much pain, and still more the attempt to swallow. For about a month he was able to take meat diet, when he became reduced to fluid forms of food. Mr. Cooper Forster could now detect a growth at the termination of the pharynx. During January swallowing became exceedingly difficult, and the patient in great distress; various modes of relief were used, but the most effective were counter-irritation by small blisters on both sides of the throat, etc. There appeared to be strong probability of the existence of epithelial cancer at the commencement of the œsophagus, in addition to chronic disease of the lung; and this was confirmed by the inspection after death. On Feb. 22 he was reduced almost to a skeleton, and swallowing was barely possible; his cough had nearly

ceased. It was found necessary to use nutrient injections, and after a few days deglutition again became partially restored for a short time. In this manner he continued, gradually wasting more and more, till, on March 19, he was unable to swallow even a drop of water; the thirst became very distressing, and he was, as he stated, "famished." It was evident that he was dying from inanition; injections had been used more or less for nearly a month, and were now the only means of administering any food; these were repeated at intervals of a few hours, but in a week they also failed, the rectum at once rejecting them. In this condition, March 26, it became a question whether the patient should be left to die suffering from starvation and thirst, or any means of relief be attempted. About a week previously, the effort of swallowing even a drop of water had produced violent coughing, and appeared to indicate a communication with the trachea. To attempt œsophatomy would have been in vain; for, as was suspected, the disease extended from the pharynx as far as the sternum. To pass a bougie would have been impossible, and would have probably produced instant death; the only means left was to make a gastric fistula. To some this operation may appear unjustifiable; but Dr. Habershon urged it as a means, not of cure, but to relieve the agonizing sense of starvation and of thirst, and this it completely effected. It was not performed till the pulse was very feeble; but even then it afforded comfort, and tended in some degree, perhaps, to prolong life—at the least, death was less painful. After consultation and deliberation among our colleagues, Mr. Forster made an opening into the stomach at the linea semilunaris. It was performed with very little suffering to the patient, without the collapse which might have been expected, and with an ease which surprised those who witnessed the operation. The edges of the mucous membrane of the stomach were stitched to the opening, and small quantities of food frequently introduced. The patient became much more comfortable, his thirst was relieved, and his hunger satisfied; he slept comfortably for several hours. After twenty-four hours, however, he was evidently sinking, and stimulants were given very freely, but with only very transient effect. He died forty-five hours after the operation. On inspection, there was epithelial cancer of the throat, extending from the cricoid cartilage to immediately beneath the sternum, where constriction was almost complete, only allowing a probe to pass. Above the constriction the coats of the œsophagus were perforated, and a small communication formed with the trachea. The lungs were emphysematous, at the right apex there was old deposit, with crepitant intervening lung. Some tubercles were studded throughout the right lung (non-cancerous), and there was considerable congestion, and some lobular pneumonia of the left lung. In the abdomen the centre of the anterior surface of the stomach had been opened. No peritonitis existed; the serous membrane was everywhere perfectly smooth. The food, consisting of eggs, milk, and some rum, had passed for four feet down the jejunum; the rest of the intestine was exceedingly contracted, but healthy, except several patches of congestion in the colon. The other viscera were healthy. One or two glands of the neck were enlarged. The fuller particulars of this case, and of the operation and treatment, with illustrative drawings, will be given in the next number of the Guy's Reports; but we have thought it right to give this early notice, that the nature of the case may be understood. The operation of forming gastric fistula or gastrotomy was shown in this instance to be performed without much suffering, without collapse, with ease, with considerable relief, and possibly, if done at an earlier period, with much more permanent benefit. It was not a trifling boon to this man to be relieved from intense thirst and the feeling of starvation.

**HEALTH OF INDIAN TROOPS.**—A letter from Cawnpore says:—"The troops appear as yet to be tolerably healthy. In Jung Bahadoor's force, however, smallpox has broken out, and cholera is fatally busy in Bengal. The 35th, at Raneegunge, has suffered severely from that disorder. It is to be feared that great losses will ensue if the men are not housed by the hot weather. The construction of barrack accommodation progresses very slowly; and, indeed, even were a sufficient amount completed, a considerable proportion of the troops would probably be unable to avail themselves of it."

THE PROVINCIAL  
PRACTICE OF MEDICINE AND SURGERY.

STATISTICAL REPORT OF THE PRINCIPAL  
OPERATIONS PERFORMED DURING  
THE YEAR 1857.

(Continued from p. 352.)

THE subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

AMPUTATIONS.

*Of the Leg.*—Case 76.—The Royal Berkshire: Mr. May.—A delicate man, aged 29, was admitted with a compound fracture of the leg. Primary amputation. Recovery. Case 77.—The Staffordshire General: Mr. Waddell.—A strumous lad, aged 13. Amputation on account of diseased tarsus. Recovery. Case 78.—The Sheffield: Mr. Barber.—A man, aged 28. Amputation on account of a large sore, which had remained from an unhealed burn fourteen years ago. Recovery. Case 79.—The Queen's, Birmingham: Mr. West.—A lad, aged 7. Primary amputation on account of crushed foot. Recovery. Case 80.—The Queen's, Birmingham: Mr. Langston Parker.—A woman, aged 48, was admitted with a compound fracture of the right leg. Secondary amputation on account of gangrene on the eighth day. Recovery. Case 81.—The Queen's, Birmingham: Mr. Langston Parker.—A boy, aged 11, admitted with his right foot crushed. Secondary amputation on account of profuse suppuration on the ninth day. Recovery. Case 82.—The Leeds: Mr. Teale.—A delicate lad, aged 17. Amputation of the leg on account of diseased ankle of two years' duration. Amputation. Recovery. Case 83.—The Leeds: Mr. Teale.—A delicate boy, aged 14. Amputation on account of diseased ankle-joint of two years' standing. Recovery. Case 84.—The Leeds: Mr. Hey.—A woman, aged 26, the subject of diseased ankle-joint for twelve years. Recovery. Case 85.—The Leeds: Mr. Hey.—A stout man, aged 44. Amputation (at his own request) of the leg, on account of an intractable and very painful ulcer, involving the periosteum. Recovery. Case 86.—The Derby: Mr. Fearn.—A man, aged 46. Secondary amputation of the leg on the seventeenth day, after a compound fracture. Recovery. The left arm had been removed by primary amputation, having been crushed in the same accident. Case 87.—The Derby: Mr. Gisborne.—A man, aged 19. Amputation on account of diseased ankle-joint of two years' standing. Recovery. Case 88.—The Liverpool Royal: Mr. Bickersteth.—A woman, aged 50, in good health. Amputation on account of malignant growth involving the foot and ankle. Recovery. Case 89.—The Liverpool Royal: Mr. Long.—A healthy lad, aged 12. Amputation on account of elephantiasis of the leg, which had occasioned much pain. Recovery. Case 90.—The Liverpool Royal: Mr. Long.—A healthy man, aged 26, whose leg had been amputated on the field at Inkermann. The bones being scarcely covered, a second amputation was performed. Recovery. Case 91.—The Liverpool Royal: Mr. Stubbs.—A healthy man, aged 26. Primary amputation on account of compound comminuted fracture. Recovery. Case 92.—The Sussex County: Mr. Blaker.—A man, aged 43. Amputation of the leg on account of intractable ulcer of eighteen years' duration. Under treatment. Case 93.—Addenbrooke's, Cambridge: Mr. Léstourgeon.—A boy of scrofulous habit, the subject of old-standing disease of the ankle. Amputation. Recovery. Case 94.—Addenbrooke's, Cambridge: Mr. Hammond.—A healthy boy, aged 11, the subject of diseased ankle. Amputation. Recovery. Case 95.—Glasgow: A boy, aged 11. Primary amputation on account of compound fracture. Recovery. Case 96.—The Sheffield: Mr. Barber

—A boy, aged 14. Amputation of the right leg on account of strumous disease of the ankle. Recovery. Case 97.—The Cheltenham General: Mr. Eves.—A boy, aged 14, in a state of the most extreme exhaustion on account of disease of the ankle-joint. Amputation. Profuse secondary hæmorrhage occurred, and was very nearly fatal, but the boy ultimately recovered well. Case 98.—The North Stafford: Mr. Garner.—Primary amputation after compound fracture. Recovery. Case 99.—The Dundee: Dr. Crockatt.—A woman, aged 40, in bad health, the subject of diseased ankle-joint. Amputation. Recovery. Case 100.—The Dorset: Mr. Curme.—A lad, aged 18, of scrofulous habit, was admitted with a compound dislocation of the ankle. Secondary amputation through the leg. Recovered. Case 101.—The Staffordshire General: Dr. Masfen.—A strumous lad, aged 17, admitted with disease of the ankle-joint and tarsus of eighteen months' duration. Amputation. Recovery. Case 102.—The Leeds: Mr. Smith.—A woman, aged 36. Amputation on account of diseased tarsus of nine months' duration. Recovery. Case 103.—The Leeds: Mr. Teale: A strumous boy, aged 13. Amputation on account of diseased tarsus, the result of an injury a year before. Recovery. Case 104.—The Leeds: Mr. Hey.—A man, aged 26. Amputation on account of diseased tarsus. Recovery. Case 105.—The Leicester: Mr. Paget.—A lad, aged 15, in fair health. Amputation on account of diseased tarsus. Recovered. Case 106.—The Gloucester: Mr. Wilton.—A healthy man, aged 40. Primary amputation on account of crushed foot. Recovered. Case 107.—The Liverpool Southern: Mr. Minahull.—A boy, aged 15. Primary amputation for compound fracture. Recovered. Case 108.—The Liverpool Southern: Dr. Nottingham.—A man, aged 45. Primary amputation for compound fracture. Recovered. Case 109.—The Liverpool Southern: Mr. Hamilton.—A boy, aged 12. Primary amputation for compound fracture. Under treatment. Case 110.—The North Staffordshire: Mr. Garner.—A lad, aged 19. Primary amputation for compound fracture. Recovery. Case 111.—The North Staffordshire: Mr. Ball.—A man, aged 62. Amputation on account of diseased tarsus. Recovery. Case 112.—The North Staffordshire: Mr. Ball.—A man, aged 47, admitted on account of a crush of the left leg. Primary amputation. Sloughing and hæmorrhage followed. Death on the tenth day. Other severe injuries had also been sustained. Case 113.—The Glasgow.—A lad, aged 18. Primary amputation on account of crushed leg. Death from exhaustion on the seventh day. Case 114.—The Glasgow.—A man, aged 23. Secondary amputation on account of severe injury to the leg. Death from phlebitis on the third day. Case 115.—The Glasgow.—A lad, aged 15, in good health, admitted on account of a compound fracture of the leg. Tetanus occurred on the sixth day, and secondary amputation was performed on the eighth. Death followed twenty-four hours after the operation. Case 116.—The Sussex County: The House Surgeon.—An intemperate man, aged 46. Primary amputation on account of compound fracture of the leg. Death on the fifteenth day from delirium tremens, with gangrene on the stump. Case 117.—The Liverpool Royal: Mr. Stubbs.—A healthy country woman, aged 25.—Primary amputation through the upper third of leg, on account of compound fracture from a machinery accident. She had an infant four months old at the breast. Death from irritative fever on the sixth day. Case 118.—The Liverpool Royal: Mr. Bickersteth.—A feeble woman, aged 60, suffering from diseased tarsus. After the amputation she did well for a while, but subsequently sank into a feeble condition and died. Case 119.—The Liverpool Royal: Mr. Stubbs.—A healthy man, aged 23, a railway stoker, was admitted with a compound fracture of the right leg and many severe bruises, having been blown up by a boiler explosion. Primary amputation. Death thirty-six hours afterwards. Case 120.—The Derby: Mr. Fearn.—A man, aged 76, the subject of diseased tarsus: after the amputation the flaps sloughed and the bones became exposed. Death from exhaustion on the twenty-eighth day. Case 121.—The Leeds: Mr. Hey.—A woman, aged 23, in fair health. Amputation through the leg on account of a tumour, the size of a cocoa-nut, which had been growing for two years from the dorsum of the foot. Death from pyæmia with purulent deposits in the lungs on the twenty-eighth day. On examination of the tumour it appeared to consist chiefly of fibrous structure. Case 122.—The Queen's (Birmingham): Mr. Sands Cox.—A very intemperate man, aged 44. Secondary

amputation on the fourteenth day, on account of gangrene after a compound fracture. Death two days afterwards. *Case 123.*—The Sheffield: Mr. Barber.—A stout woman, aged 67. An opium-eater. Amputation of the leg at her own request, on account of a large intractable ulcer; severe dyspeptic symptoms occurred afterwards. She died of exhaustion four months after the operation. *Case 124.*—The Royal Berkshire: Mr. Moxhay.—An intemperate woman, aged 60. Primary amputation, on account of a compound fracture of the ankle. The flaps sloughed, she sank into a typhoid state, and death took place on the ninth day. *Case 125.*—The West Norfolk: Mr. Sayle.—A healthy boy, aged 13. Secondary amputation, on account of gangrene on the sixth day, after a comminuted fracture of the leg extending into the knee-joint. The posterior tibial artery and nerve had been torn through. On the second day after the operation lockjaw showed itself, and general tetanus was rapidly developed. Death followed thirteen hours after the first stiffness of the neck. *Case 126.*—The North Stafford: Mr. Ball.—A man, aged 69. Amputation of the leg, on account of an old ulcer. Death from exhaustion in the third week. *Case 127.*—The North Stafford: Mr. Turner.—A man, aged 22, in good health. Compound fracture of the leg and ankle. Primary amputation. Death. *Case 128.*—The Glasgow.—A man, aged 46, the subject of sloughing ulcers of the leg, and necrosis of the tibia. Amputation. Secondary hæmorrhage. Death from exhaustion on the fifth day. *Case 129.*—The Glasgow. A woman, aged 34. Primary amputation, on account of compound fracture. Death.

## SUSSEX COUNTY HOSPITAL.

### INGUINAL ANEURISM—LIGATURE OF THE EXTERNAL ILIAC ARTERY—RECOVERY.

(Under the care of Mr. E. J. FURNER.)

[Reported by Mr. F. JOWERS, House-Surgeon.]

James Fawcett, aged 30, a tall, fine, strongly-made man, a master-mariner by occupation, moderately sober, much exposed to wet, cold, and severe toil, but usually enjoying good health, was admitted into the Sussex County Hospital, under the care of Mr. Furner, September 5, 1857, with a large pulsating tumour in the right groin, of three months' duration. He complained much of pain in this swelling, extending down the thigh to the knee, in which latter situation it was more severe than in the swelling itself.

He gave the following history:—

About January last he began to be troubled with darting pain in the groin, especially after any unusual exertion, but not so severe as to cause him very much inconvenience. Three months ago, after many hours very severe labour in lifting ballast, he was attacked with more than usually severe pain in the groin, and his attention being directed to the part, he found a swelling the size of a walnut.

This swelling was "beating," and, according to the account of his wife, pulsated so forcibly as to "jerk her finger off." He showed the swelling to various Surgeons at different seaport towns, and was treated for a bubo; leeches, poultices, and fomentations being applied to "bring it to a head, that it might be opened."

All this time he suffered acute pain, especially at night, so that he scarcely knew what it was to obtain any regular sleep, but not till three weeks before admission did he relinquish his occupation.

Fortunately he then came under the notice of my friend, Mr. Fuller of Shoreham, who at once diagnosed the real nature of the case, and advised his removal to the hospital.

He had no recollection of any sudden blow or strain, but his work was often extremely laborious; thus, for instance, he was sometimes at the helm for twenty hours at a time.

On examination there was found in the right groin a large pulsating tumour, measuring four inches in diameter, extending from the external abdominal ring outwards, and as much above as below Poupart's ligament, and apparently going deeply into the pelvis. It was circular in form, tolerably uniform on its surface, firm and incompressible, and pulsated with a strong uniform swelling, synchronous with the pulse, and without any thrill.

At one point only, at its upper and inner margin, could a

slight bruit be detected. A faint bruit was also heard in the course of the femoral artery. There was no œdema of the limb. The skin over the swelling was marked by the scars of old buboes; otherwise it was healthy.

He was ordered to lie in bed, to apply cold lotion to the swelling, to take a mercurial purge, and have a spare diet.

The tumour made such rapid progress that it was deemed advisable not to delay the operation, and on the 11th September, six days after admission, it was performed. The swelling then measured more than five inches in diameter, and was much more prominent.

The external incision was commenced about an inch above the external abdominal ring, and carried upwards and outwards in a curved direction to the extent of five inches and a half. The only check that occurred in the operation was from the remarkable contraction at each application of the knife of the abdominal muscles, which were developed to an unusual degree, and interfered considerably with the free use of the knife. The ligature was applied in the usual manner, very little blood was lost during the operation, the only vessel wounded being the superficial epigastric, which was immediately secured, and the entire operation was completed, including the administration of chloroform, in something less than twenty minutes.

By the liberal application of leeches and the free use of calomel and opium he recovered from a severe attack of peritonitis, and was going on fairly till the evening of the ninth day, when, after sleeping all the afternoon, he awoke shivering, and complaining of a sense of weight and coldness in the tumour. These symptoms subsided on the administration of some ether and laudanum, but recurred on the following evening about the same time. The tumour was now soft, and doubtfully fluctuating.

On the twelfth day the tumour was softer, tender, and more prominent; he had but little sleep during the night, being kept awake by a sense of weight and fulness in the abdomen in the immediate vicinity of the swelling; and early in the morning of the thirteenth day a gush of dark bloody fluid took place from the wound. All the dressings were removed, and the wound exposed to the air. Some hours afterwards the discharge had somewhat increased, but was now more evidently mixed with matter. It smelt like decomposed animal matter, and the microscope showed little besides exudation cells; there were but few corrugated and worn-out blood-cells. The swelling was very much flattened, less tender, and less fluctuating; and pressure over it increased the discharge from the wound, which had a good appearance. The patient looked and felt well.

On his return to bed the limb was wrapped from the foot to the groin in cotton wool, and raised on pillows.

About six hours after the operation he complained of intense pain in the calf of the leg, which felt, to use his own expression, "as though it must burst." The right limb was only two degrees colder than the left. They were respectively 76° and 78°. He took half a drachm of laudanum, and was soon free from pain.

At midnight, being rather restless, he took fifty drops of laudanum, and obtained some good sleep at intervals.

On the following day he had a tranquil expression, and was quite comfortable, save that there was some slight tenderness in the region of the wound, and he was somewhat troubled with flatulence, to which he was subject.

He was directed to take a grain of crude opium every four hours, and to have a light poultice over the abdomen.

This treatment was followed by marked relief. In the evening he was quite easy, the abdomen scarcely tender, and the pulse but little over 100. The use of the opium persisted in, and he continued doing well till the evening of the third day after the operation, when his pulse rose almost suddenly from 74 to 100; the abdomen became painful, tender, and distended, and vomiting with hiccough set in.

The discharge became good pus, and on the sixteenth day the ligature came away. On the eighteenth day another gush of thick blood-stained pus took place, with three or four large clots of blood. He had on the previous day felt some uneasiness in the swelling, and this was followed by marked relief.

He was now apparently getting rapidly well, when, early on the morning of the twenty-fifth day following the operation, and the ninth after the separation of the ligature, there was a sudden gush of florid and seemingly arterial blood from

the wound, to the extent, as nearly as could be ascertained, of sixteen ounces.

The patient was perfectly quiet at the time, but attributed the bleeding to his having used the limb while shifting his position some short time before; he then inadvertently made use of the affected limb to push against the foot-board.

As the hæmorrhage had entirely ceased when seen by the House Surgeon, and showed no disposition to recur, no compresses were used; but the patient was placed upon a more spare diet than before, and he was carefully watched, as he had been from the commencement, by the dressers and nurses. He said that after the bleeding took place he had more sensation in the limb than he had had since the operation. The posterior tibial artery was detected for the first time.

After the hæmorrhage, which did not recur, there was little to note save the steady progress of the case towards perfect recovery. For some time afterwards the wound did not assume the healthy appearance it had before, and not till the eleventh week after the operation could it be said to be fairly healed.

He was discharged Dec. 2, and has since performed several voyages. The wound is firmly cicatrized, and there is no tendency to ventral hernia.

SATURDAY, APRIL 10.

#### ELCHO v. COWPER.

HAVING in our last article (March 27) distinctly stated the PRINCIPLES on which a Medical Reform Bill ought to rest its claims for support, we proceed to examine the provisions of the two Bills now before Parliament—that of Lord Elcho and that of Mr. Cowper.

This analysis we shall attempt to make mainly upon the salient points on which the two Bills differ, as well in principle as in the machinery for carrying out executive details.

Both Bills are agreed as to the necessity of two out of the three great principles we have insisted on:—1. That every Medical Practitioner should have the right of free practice throughout the United Kingdom, without hindrance from local jurisdiction; and, 2. That the names of qualified Practitioners should be inscribed in a Register, to enable the public to ascertain their qualifications, and so to distinguish them from the unqualified.

Bearing on the powers, and the direction in which the Council may exercise their powers, there appears to us a significant difference, involving in the details of Registration principles of some importance, in the latter part of paragraph xxv. of Mr. Cowper's Bill, compared with paragraph xxxiv. of Lord Elcho's. By the former Bill, the insertion of additional qualifications in the Register may be made, "on payment of such fee as the Council may direct." By the corresponding paragraph in Lord Elcho's Bill, no fee is required for any such additional record. In short, while Lord Elcho's Bill proposes distinctly a fee of not more than £25 for all, the fees by Mr. Cowper's Bill are left undeter-

mined; and we confess to not being able to understand the principle on which they are to be exacted, or the mode in which they are to be paid. This is an important difference, considering the mode in which the Council of Mr. Cowper's Bill is proposed to be constituted; and the proposal may be used as an argument of some weight against the constitution of the Council as proposed by Mr. Cowper.

Those who are to be registered *simpliciter* under the Act, as already holding legal rights to practise, and who will thus at once be recognised as "the legally qualified," are defined similarly in the appended schedule of either Bill, namely, in schedule A of Mr. Cowper's, or in schedule B of Lord Elcho's. The only difference is, that Mr. Cowper's measure admits those who have been made Doctors of Medicine by the Archbishop of Canterbury, while Lord Elcho's does not. If such an authority for the creation of a Doctor is duly inserted after the name of the person there may be no objection to this concession, as the simple statement of the fact and source of the right may be amply sufficient, (in the absence of any other qualification,) to inform the public that such a man has not necessarily any training or knowledge of his Profession, and ought not to be trusted. Again, the Register proposed by Lord Elcho is simply alphabetical, whereas Mr. Cowper leaves to the Council the power to make a Register, or Registers, after their own fashion, which would possibly lead to the very objectionable plan of a separate register for Physicians, Surgeons, and General Practitioners. University Graduates who are not members of corporations would thus have a most indefinite position, not being recognised under any of the above designations. Both Bills also agree as to the necessity of publishing one uniform Pharmacopœia for the Three Kingdoms.

It is on the third great principle that the battle-ground must be contested. It is the manner in which future candidates for entrance into the Profession are proposed to be admitted on which differences exist of vital importance. We contend that every Practitioner, whatever higher honours or distinctions he may subsequently attain, should be required to pass through one common examination, which should be a fair, uniform, and sufficient test of education and of qualification, practical as well as theoretical. Thus all may start fair in the race of life, and strive to rise from this the lowest and most common level in Medical acquirements.

Let us, then, compare the provisions of the two Bills, by which it is proposed that admission to the Medical Profession is in future to be obtained.

Lord Elcho proposes to institute two Boards of Examiners—one for the preliminary examination of candidates as to their general education; and another for the examination of candidates as to their professional education. The examiners who constitute the first Board, to deal with the preliminary attainments of the candidate, are to be appointed by "the General Council," to hold office during the pleasure of the Council, and to receive pay.

One Professional Board is to be appointed for England, one for Scotland, and one for Ireland. The number of examiners is as yet undetermined, but left to be decided by the General Council. The professional examiners are to be appointed from year to year, and to be eligible for reappointment; but the Professional Board of Examiners is not to be appointed by the General Council.

The Examiners constituting the Board for England are to be appointed by the College of Physicians of London and by the College of Surgeons of England, and (until 1865) by the Society of Apothecaries of London respectively; and of Examiners to be appointed by the Universities of Oxford, Cambridge, and London respectively.

The Examiners constituting the Board for Scotland are to be appointed by the College of Physicians of Edinburgh, by the College of Surgeons of Edinburgh, and by the Faculty of

Physicians and Surgeons of Glasgow respectively; and of Examiners to be appointed by the Universities of Edinburgh and Glasgow respectively, and by the two Universities of Aberdeen conjointly.

The Examiners constituting the Board for Ireland are to be appointed by the College of Physicians of Ireland, by the College of Surgeons of Ireland, and (until 1866) by the Governor and Company of the Apothecaries' Hall of Dublin respectively, and of Examiners to be appointed by the University of Dublin and by the Queen's University respectively.

Such is the machinery for the examination of those who would enter the Profession according to the letter of Lord Elcho's Bill. They would thus pass a preliminary examination, unless they had already graduated in Arts at some University of the United Kingdom, or at some Foreign University approved by the Council. Having passed this preliminary examination and obtained the certificate, they would be entitled to present themselves for the professional examination; and this professional examination would be thus far publicly conducted, that the members of the Council, and any person deputed by the Council, and any one registered under Lord Elcho's Act, would have free access to all examinations conducted by the Professional Boards.

But Mr. Cowper's Bill leaves things as they are. Every one of the *twenty* licensing and examining bodies, as they at present exist, would still, according to his Bill, be the examining bodies for the several parts of the United Kingdom. "Diplomas, degrees, certificates of the said examining bodies respectively, shall be evidence of the qualifications which are to entitle persons to be registered under this Act, subject to the orders and regulations of the General Council."

Now, nothing can be more varied in their nature than the examinations at present conducted by these *twenty* examining bodies. No two examine alike. No two exercise their vocation through the same number of Examiners. They do not all examine students on the same topics. They are not equally rigid in their tests. In short, a more objectionable system than the present cannot be devised; and we are only surprised that the Archbishop of Canterbury has not been made an *examining body*, to complete the legitimate variety, and make the confusion still more confounded. Although it is indirectly implied in Mr. Cowper's Bill that the present Corporations shall cease to hold their individual powers as *licensing bodies*, yet they are thus to be maintained as *examining bodies*, and on the results of these examinations the licences are to be granted or not by the Council. We showed in our last that the existing state of things fosters a "competition downwards"—a progressive deterioration in the tests of proficiency which tends to preserve the attainments of the members of the Medical Profession merely at the level of mediocrity. We recognise in the measure proposed in Mr. Cowper's Bill—(namely, to maintain the present examining bodies, withdrawing their executive powers as licensing corporations)—a step most prejudicial to the interests of the Profession and dangerous to the Public. The responsibility of these bodies as licensing Boards is to be withdrawn, and the responsibility, of examining merely, is to be thrown upon them. What, then, would be the nature of the competition? It would still be a competition of the downward kind among those examiners, of whom many are at the same time teachers in our Schools of Medicine. Such examining teachers would be greatly tempted to permit their pupils to pass with an easy examination. The practical result would be, that students would flock to those schools where they would be examined by their own teachers, and the examining bodies where no schools exist would only be called upon in rare instances to exercise their vocation. This proposed measure would thus furnish a most inefficient test of professional acquirements, and a most unfair test, because it would open at least twenty different doors into

the Profession; and the door-keepers, as we shall by-and-by see, would be held responsible by a no less heterogeneously composed Common Council. Moreover, we do not see that any test of preliminary education is to be required by Mr. Cowper's Bill; and of all reforms there is not one of which our Profession stands more in need, than a measure, steady, uniform, and reasonably exacting in this direction. Lord Elcho's proposed plan of examining appears far better than Mr. Cowper's. It seems wise and liberal to concede to the existing Corporate Bodies and Universities the sole right of appointing those who are to constitute the Boards of Examiners. We apprehend that Lord Elcho's Boards, in the exercise of their vocation, will be analogous, in their mode of operation, to the members of the legal profession when they go on circuit. In certain towns at certain fixed and definite periods of the year, a sufficient quorum from the Examining Boards would hold their sittings, announcing to all whom it may concern that they are ready to examine those students of Medicine who have conformed otherwise to the requirements of the Act. It would not be easy to propose a more simple, just, uniform, and efficient mode of executing a most important and responsible function.

Now, between the Medical Profession, as a national institution, and the Public at large, to whose necessities it ministers, there must be some medium of inter-communication. There must be some body whose sole duty shall be to see that the Public are fairly and justly provided for, and who shall see that the laws regulating the Medical Profession shall be efficiently carried out.

This medium of inter-communication must be an executive body, which shall come between the Public and the Profession on the one hand, and between the Government, the Public, and the Profession, on the other.

Both Bills attempt to provide for this most important requirement by a Common Council. The question as to the constitution of this Common Council is essentially a question of executive detail, and therefore a fit subject for decision in Committee of the House. It is not to be compared in importance with the great principles on which we have considered a Medical Reform measure ought to be framed; nor ought it to take precedence of plans of Reform embodying those principles. It is, however, a topic on which much misapprehension and misrepresentation prevails; and we must endeavour to put the matter as clearly as we can before the Profession.

One grievous misrepresentation is, that the Council, as proposed by Lord Elcho, throws the management of the Profession into the hands of the Crown. Now, to show the obvious fallacy of such a doctrine, we must look to the functions the Council would be required to perform. The proper function of the Common Council, we imagine, would be to see the spirit and letter of the law fully carried out. With the organisation and management of the Profession, the Common Council could have nothing whatever to do. Over the 19,000 members of the Medical Profession it cannot have control. They may form themselves into clubs, societies, corporations, educational establishments; in short, do as they please as regards their internal organisation. The Council could take no cognisance of their existence, unless they infringed the laws which it is proposed the Legislature shall enact. We conceive, however, that the Common Council would have a most important duty to perform, in that they ought to be responsible to Parliament and to the Public, that the Medical Act of 1858 be worked according to law. It would be their undoubted business to see the great principles of the Medical Reform Bill fully and efficiently carried out by every executive measure proposed by the Act. In the working of the Anatomy Act through its Inspectors we have an apt illustration of what we conceive to be the position of the Medical Council in relation to the proposed Medical Reform Measure. The Inspectors of Anatomy appear to stand in

their relation to the Anatomists, the Public, and the Government exactly as the Common Council ought to stand in relation to the members of the Medical Profession, the Public, and the Government. The Inspectors of Anatomy have nothing whatever to do with the organisation or management of the business of the Anatomists. They cannot interfere with the distribution of bodies in the dissecting-room, nor can they interfere between the teacher of Anatomy and his pupils. Their sole function is to carry out, under Her Majesty's Government, the provisions of Warburton's most praiseworthy measure. They are the immediate servants of the Government, and, as such, are responsible to Government; and, if such a view of their position is the proper one, we can see no other alternative than that Government ought to appoint those servants who are to do the work of the Government. If we saw that it was part of the duty of Lord Elcho's proposed Council to interfere with the organisation of the Profession, we should decidedly object to the Government having the nomination of them. But the Council so constituted has no such power. *It does not even appoint the examiners*, as we have seen. On the other hand, Mr. Cowper's Council, as constituted, is highly objectionable, if the liberty of the Profession is to be maintained. The 19,000 members of the Profession who have no interests or sympathies in common with any Corporation or University, are, by the enactments proposed in Mr. Cowper's bill, at once entrusted to the tender mercies of the Corporations and the Universities. Mr. Cowper's Council is that which was proposed by Mr. Headlam in his Bill of last year, viz.:—seventeen members of the Universities and Corporate Bodies, with six members nominated by the Crown, who are to manage details which were made in former Bills, and are now made in that of Lord Elcho's, in a straightforward and distinct manner, the subject of special clauses. Such clauses confessedly give the Council of Mr. Cowper's Bill great powers for good or for evil, so much so that it is deemed necessary to put them under a salutary restraint, namely:—to submit all their "orders and regulations" for approval to Her Majesty in Council, a month's public notice having been previously given. The question cannot fail to suggest itself.—Is such a heterogeneously constituted body as the Council proposed in Mr. Cowper's Bill, the fit depository of executive powers of such an important nature as are proposed to be entrusted to them? We think not. The powers entrusted to them ought not to be entrusted to any Council; and, if the Legislature is to provide a measure of Medical Reform founded on those great principles we shall continue to advocate, and which recommend themselves to all, the Government ought to nominate those who are to be responsible to the Public and the Legislature for the proper working out of the executive details of such a measure.

#### THE WEEK.

A case of considerable Medico-ethical importance has been much talked about in professional circles during the last few days. Some two months ago, Mr. Philbrick, a highly respectable Surgeon of Stamford, was called in to see a gentleman in that neighbourhood, and on the following day it was suggested that a homœopathic practitioner, named Bell, should be sent for from London. Mr. Philbrick very naturally objected, and Dr. Paley, of Peterborough, was called in. After a few days Dr. Paley's attendance was dispensed with, as the homœopath Bell had undertaken the cure, which was one of retention of urine; but Mr. Philbrick was requested to attend as the Surgeon, and use the catheter. We copy the following statement from a published letter of Dr. Pratt, and Messrs. Morgan, Howard, and Eddowes, of Stamford:—

"Mr. Philbrick again declined to act with the homœopathic gentleman, requesting to be allowed to withdraw, and suggesting that a homœopathic Surgeon should be telegraphed for from London to accompany Dr. Bell, as he did not think that one would be found in Stamford to act as he was desired. The family, however, obtained the assistance of Mr. Jackson, F.R.C.S., and Senior Surgeon to the Stamford Infirmary, who undertook, according to the statement of the lady, to 'do what was necessary, and act under Dr. Bell's orders'—from his own account, to attend to the surgical department *only*, not even seeing Dr. Bell on the medical treatment. On the 26th, the patient not being so well, another opinion was desired, and Dr. Bell was requested to obtain the services of Mr. Fergusson, of George-street, Hanover-square. He was successful, and they proceeded together into Northamptonshire, where Mr. Jackson met them at — Park; whereby it is supposed that he countenanced this sort of *fusion*, the orthodoxy of which is questioned. Mr. Fergusson states that 'his services were required solely as a Surgeon; and, as far as he was concerned, there was no consultation on the subject of homœopathy.' The patient is, we believe, convalescent, and has now placed himself under Mr. Jackson's care, Dr. Bell having taken his leave."

Considerations of very grave interest are excited by a perusal of the above statement. It is quite clear that it is the duty of every Surgeon to afford relief to any patient he may be called to, and that the Profession would sink in public estimation if any mere question of etiquette could lead a Surgeon to refuse his best aid to the suffering; but it is equally clear that no Surgeon can be expected to consult or attend with any one to whom he has objection either on personal or public grounds, still less with the professors of any system of fraud and folly; and no man in Mr. Fergusson's high position could be reasonably expected to accompany a notorious homœopath on a professional visit to the country. By doing so, great encouragement is afforded to what has been well termed a "gigantic swindle," and regular practitioners are disheartened. We must defer until next week, however, a complete discussion of this question.

The star of St. Bartholomew's is in the ascendant. The three Court appointments recently made have all fallen to the share of its Surgeons: Mr. Wormald is named for the vacant chair in the Court of Examiners at the College. Mr. Lawrence has got the Sergeant-Surgeoncy; and instead of one appointment of Surgeon-Extraordinary to the Queen, which was expected, two have been made, a long existing vacancy having been filled up, and these have been bestowed on Messrs. Stanley and Paget. Not a word can be said against either appointment. Mr. Stanley's long services and high character could not be passed over with justice, while the younger and working men of the Profession will look to the elevation of Mr. Paget as a most encouraging proof that ability and industry will obtain their reward without the ordeal of the wearying period of "hope deferred," that "maketh the heart sick." No official announcement has been made that the vacant Surgeoncy to Prince Albert has been filled up; but it is currently reported that Mr. Arnott has been selected for the post, which we need not say he has well deserved and would worthily fill.

A matter of considerable delicacy is discussed just now rather freely, and some attempts have been made to organize a movement upon which we feel called to offer a few remarks. It has been felt after some of the late annual elections to the Council of the College of Surgeons that the system of re-election as a matter of course, and of election by mere seniority, was not a good one, and that means should be adopted to select the Council from the most distinguished Surgeons among the Fellows. This feeling is so

strong and general that it must lead to some result, notwithstanding the extreme difficulty of the case. All must agree that it is undesirable to elect inefficient men; but in trying to avoid this evil we must be careful not to incur a greater by setting up a regular system of caballing and canvassing, which might give a pre-eminence to noisy men of doubtful or slender character, and lead our best men, upon whom must devolve the maintenance of the future dignity of the Profession, to shrink from the rude contest. It would appear better to leave future elections to the free exercise of individual feeling, than to set up any organized system of opposition to gentlemen who may be objected to on general or particular grounds. This course might speedily and effectually accomplish the end we should all wish for, if every Fellow determined to set aside all personal motives, and vote strictly and conscientiously for the good of the College and the Profession. Our body suffers much in public estimation from fierce squabbles, and we ought to try as much as possible to avoid them.

The Medical Reform Committee of the British Medical Association met on the 1st instant, and after taking Mr. Cowper's Bill into consideration they agreed to "recommend it with alterations to the Association at large." The alterations suggested are compulsory preliminary examination in general knowledge; a more definite provision for uniformity of qualification "as far as practicable;" the omission of the clause providing that "no person shall be erased from the register on the ground of his having adopted any theory in the practice of Medicine and Surgery;" and the provision that each member of the general council should hold office for a term not exceeding five years, but should be capable of re-election. Thus the association which once supported the very Bill of the Select Committee of the House of Commons now brought in by Lord Elcho, and then Mr. Headlam's Bill of last year, now comes round to a Bill by which the very evils are perpetuated which the Association has so long endeavoured to reform.

Another of our veterans has joined "the nations under ground," Sir James McGrigor, who held for so many years the important post of Director-General of the Army Medical Department, died on the 2nd instant at the age of 87. His active services in the Army from 1793 to 1815 in the East and West Indies, the Walcheren expedition, and as chief of the Medical Department in the Peninsula under the Duke of Wellington, obtained for him the high post he so long filled with credit to himself, and advantage to the service. He was a Knight Commander of the Bath, had received several foreign decorations, and was Physician-Extraordinary to Her Majesty. We shall take an early opportunity of giving a full biographical sketch of his career.

## REVIEWS.

### *Clinical Lectures on the Principles and Practice of Medicine.*

By JOHN HUGHES BENNETT, M.D. F.R.S.E., Professor of the Institute of Medicine, and Senior Professor of Clinical Medicine in the University of Edinburgh, &c. 2nd Edition. Pp. 951. With 468 woodcuts. Edinburgh: 1858.

EVERY one is conscious that a new life has been for many years past gradually infusing itself into the theory and the practice of medicine, and that what may be called the red-tapism of the practice has been, and is, undergoing a thorough questioning. It will be the business of the historian at some future day calmly to appreciate the causes which have brought about these many changes—this actual revolution over the

face of old medicine. We are, at this period of transition, ill able to investigate their value. This much, however, is certain, that this new condition of things has arrived coincidentally with the amazing advances in a knowledge of the pathology and the diagnosis of diseases which have been made in modern days. The knowledge thus obtained has plainly taught us how much we have had to unlearn; how many errors and grievous fallacies, which have received the approbation of centuries, we have been compelled to surrender. And even yet the battle has to be fought against ancient prejudices and routine.

If we were to describe in a word the distinction between the model Physician of ancient and of modern days, we should say that the former was a polypharmical and the latter a physiological Physician. The former trusted, as we do now, to his experience and to his theory, and was satisfied with the results; for his experience seemed to show him that they were good. But, happily, observers now require something beyond the mere assertions of individual experiences as proofs of the correctness of methods of treatment. This *experimentum crucis*, this crucible, this experience, has been so often found a faulty guide, that we have been compelled to seek a test whereby to try its real worth. We are now only beginning to discover the clue to the history of these fallacies of experience. We are beginning to take due account of certain physiological and pathological laws, which have heretofore been ignored by the therapeutical Physician. The power of nature as a curer of disease is now admitted into our systems; but even yet its power is acknowledged more theoretically than practically.

Now we cannot but think it a reproach to our brethren that, in all this struggle against disorder, natural laws should be so little considered, and artificial means so profusely resorted to. Put by the side of luxurious polypharmacy and multifariousness of succedanea, the fact stated by Dr. Bennett at p. 104:—"Of all the causes of disease, irregularity in diet is the most common; and of all the means of cure at our disposal, attention to the quantity and quality of the ingesta is by far the most powerful." Now with this golden rule well fixed on the tablets of his memory, and a goodly store of globules in his pocket, the vilest of homœopathic swindlers might compete with the most orthodox polypharmaceutical Physician who neglects this rule. The polypharmacists have taught the public that for all diseases drugs were the only cure, and theirs is the fault if the public still demand such remedies; and the fault that, so often disappointed at the results, they rush into the arms of brazen-faced quackery.

Dr. Bennett in his book brings the practice into accordance with the theory of the day, and he does this in a bold and masterly manner. The work is one of a very elaborate kind, and must have cost him great labour. It contains about 950 pages, and 468 beautifully-executed woodcuts. At every page the reader will find the impress of the author's personal observation. His points of practice are exemplified by the details of 219 carefully-reported cases, selected from his clinical experience.

Few men of his age have striven harder than Dr. Bennett to advance his Profession to the position of a really scientific art; and we gladly seize this opportunity of acknowledging what he has done for it. The Profession are indebted to him for the introduction of cod-liver oil into this country. He was, we believe, the first person who publicly taught the use of the microscope. He also introduced the German system of clinical instruction into the Edinburgh Infirmary, and with excellent results. His investigations into pulmonary and cancerous diseases are well known; and he undoubtedly was the first person who published a case of leucocythemia, showing that corpuscles resembling pus-corpuscles were present in the blood, without any co-existing pyæmia. All his labours, and they embrace a wide field of observation, have tended to one end—the scientific and honourable advancement of our Profession.

It is out of question for us here to attempt to cope with the particulars of this new work; we can do little more than commend the careful study of it to our professional brethren, and especially to the rising generation. The chapter on the "Examination of the Patient," tells the student how to apply the stethoscope, the microscope, and chemical agencies in the diagnosis of disease. Then comes the part which treats of the principles of medicine. These are, in fact, the pathology of diseases; and then we have the detailed history of special

diseases. Dr. Bennett combats Dr. Burrows' theory of the cerebral circulation, and sustains Dr. Kellie's. We certainly think the fact of the brain not being withdrawn from atmospheric pressure is not decided by Dr. Burrows' experiments; most assuredly, at all events, it must be subjected to varying pressure, coincidentally with the varying force applied to the blood by the heart's varying contractions. We trust some physiologist will reconsider this question. Speaking of kidney diseases, our author gives an opinion which is exactly opposed to Dr. Johnson:—"I have given diuretics in all stages of the disease with the best effects. Nor have I seen any bad results from the practice." Dr. Johnson says, *per contra*:—"With our present knowledge of renal pathology, it is clear that the practice of giving diuretics in acute nephritis is most unjustifiable." We recommend to consideration the details of cases 153 and 163 on this subject given by Dr. Bennett.

We need hardly say, that bleeding as a remedy for acute inflammation is everywhere eschewed throughout this book. Theoretically and practically, Dr. Bennett denounces its use to this end. This is a revolution indeed! This is the first time in the history of modern medicine that the gauntlet has been fairly thrown down in a bold and uncompromising way. Inflammation, Dr. Bennett teaches us, is not a fiercely sthenic flame; it is a disease of weakness. It is unfair, however, to Dr. Bennett to suppose that he rejects the lancet altogether. On the contrary, we find that in congestions of heart and lungs, he often speaks of the service it does. Only in inflammations it is useless, and worse than useless. But we must not be tempted into this discussion at present.

Dr. Bennett speaks favourably of Dr. Horace Green's method of injecting the bronchi with solutions of nitrate of silver, in bronchitis, asthma, tubercular diseases, etc. He has several times performed the feat (for we must call it such) himself; but he admits that further experience of its use is necessary before judgment of it can be given. Two drachms of a solution (3ss. of nitrate of silver to 3i of water) when injected into the trachea produced in one case only a feeling of warmth in the chest. In some individuals, however, the use of the injection is impossible. The irritability of the parts varies infinitely in different persons.

We would call attention to the author's classification of skin diseases. He has much simplified this jumbled department of pathology. He combats the idea of those who think *favus* not of a vegetable origin; "if," he says, "long hollow filaments, with partitions at intervals, containing molecules within their cells, springing from an unorganised granular mass, and giving off towards their extremities round, oval bodies, or spores in arranged bead-like rows, be not vegetables, what are they? The animal tissues present nothing similar, while numerous plants long known to botanists, present the same identical structure." P. 803.

The views of Dr. Jenner and Dr. Stewart on fever are not received as proven by Dr. Bennett. "Without denying the existence of various kinds of eruptive fever, I am of opinion that this doctrine has not been established." P. 873. Dr. Dundas's opinions of the cutting short of continued fevers by quinine, Dr. Bennett has found like many another observer, will not stand the test of trial.

In conclusion, we have only to recommend this volume, with the most unqualified praise, to the attentive consideration of the practitioner and the student. We have met with no work of late years on the principles of Medicine more likely to advance the true and rightful study of our art.

*The British and Foreign Medico-Chirurgical Review, or Quarterly Journal of Practical Medicine and Surgery.* No. XLII. April, 1858.

THE present number of the *British and Foreign Medico-Chirurgical Review* is full of interesting matter, many of the subjects discussed having lately attracted much attention both in and out of the Profession. Among the more prominent of the articles is one on "Wines and their Uses," in which the chemical history of wines is very ably handled, and the use of wine, as well as its abuse, are candidly and impartially explained. The article is founded upon Dr. Henderson's "History of Ancient and Modern Wines," published in 1824, or the more recent treatise of Mulder, on the "Traité sur les Vins de France," by Batioliat, and upon what appears to be an extraordinary revela-

tion as to the adulteration of wines, contained in a book lately published called the "Wine and Spirit Merchant's Own Book."—In connexion with the Third Edition of the celebrated work on Prostitution in Paris, by the late Parent Duchâtelet, and the Treatise published last year by Mr. Acton on the same subject, the question of the "Great Social Evil" is examined in its moral as well as Medical bearings. The reviewer adopts a high moral tone in treating this delicate topic, and while agreeing with Mr. Acton in the propriety of bringing the evils attendant upon Prostitution before the notice of the public, he nevertheless deprecates any recognition of this vice by the Legislature, and objects to the formation of any new special Hospitals for the treatment of venereal diseases. He thinks that in place of the loose notions now prevalent, a more wholesome code of morality should be impressed upon the young men of the present day; and on the principle that the supply is regulated by the demand, he infers that virtuous habits on the part of the male sex would necessarily discourage the trade of prostitution on the part of the female. It is also urged that society ought not to punish the weaker creature with the severity which it now exercises, while it allows the other party, who is at least equally criminal, to escape altogether from censure. On the whole this article is exceedingly well written, and will command general attention.—The Review on the Report of the Commissioners appointed to inquire into the Regulations affecting the Sanitary Condition of the Army, gives a well-digested abstract of the chief points touched upon by the Commission, and of the evidence on which its conclusions were founded. It is to be hoped that the recommendations contained in this Report will be forthwith carried into effect, even for the sake of the soldiers, whose sanitary condition is at present anything but favourable, and also of the Military Medical officers, whose numerous grievances have been repeatedly brought before the notice of the public.—Among the other articles in the present number of the *British and Foreign Quarterly* are, one on Marshall Hall's "ready method" of resuscitation after apparent death from drowning, and other forms of Apnoea, in which article the comparative merits of the new and old methods of restoring suspended animation are impartially weighed; one on Dr. Inman's treatise on Spinal Irritation, which possesses much interest, as offering an ingenious explanation of many affections of that class; one on Scanzoni's Manual of Obstetrics, and the work of the same author on the Diseases of the Female Generative Organs; and others of equal interest upon various branches of Medicine, Surgery, and General Science. The Original Communications consist of a "Pathological Report of the Middlesex Hospital, being an analysis of the principal morbid appearances observed in 180 post-mortem examinations," by Dr. Van der Byl; and a second Original Communication is by Dr. Harley, entitled, "An Experimental Inquiry into the Function of the Supra-Renal Capsules, and their supposed connexion with Bronzed Skin." Dr. Harley has been led to doubt, although not to disbelieve, the existence of this connexion, and he has collected together a number of cases, with post-mortem examinations, in aid of his inquiries into the physiology and pathology of the bodies in question. The rest of the number contains a copious Bibliographical Record, and the usual Chronicle of the Medical Sciences, consisting, this quarter, of Reports on Micrology, Forensic Medicine, Medicine, Surgery, and Midwifery, by Dr. Ogle, Dr. Richardson, Dr. Sieveking, Mr. Chatto, and Dr. Barnes.

*Handbook of Zoology.* By J. VAN DER HOEVEN. Vol. ii. Translated from the Second Dutch Edition by the Rev. W. CLARK, M.D., F.R.S. Cambridge and London, 1858. 8vo, pp. 775.

THE first volume of this Handbook included the invertebrate animals. The vertebrate animals form the subject of the second and concluding volume. The whole work is characterised specially by the large amount of anatomical information it contains, differing in this respect from most other zoological works. Students of Comparative Anatomy and Physiology, and persons who specially study Zoology, will find in the learned work of the Leyden Professor a standard authoritative work of reference. The Professor of Anatomy in the University of Cambridge has performed his office of translator with great care and ability.

*The Nature of Inflammation, and the Principles on which it should be treated, examined from a common-sense point of view.* By THOMAS INMAN, M.D., Physician to the Northern Hospital, Liverpool. To which is added, a *History of Atheroma in Arteries, its Nature and Alliances.* Liverpool: 1858.

In the essay on Inflammation, Dr. Inman makes no pretensions to the elucidation of any obscure points in the pathology of that condition. He merely considers the subject practically, and chiefly in reference to the results of treatment. In common with some other writers, both of ancient and modern times, he regards inflammation as a disease of debility, and depletory treatment he declares in general to be not only unnecessary, but injurious. He seems to think that the Medical practitioners of the present day have carried bleeding and other antiphlogistic measures to an unjustifiable extent, and that the progress of the homœopathic quackery is in great part due to the beneficial changes sometimes produced upon disease by leaving the patient alone to the unassisted powers of nature. Dr. Inman observes, with considerable truth, that the chief patrons of globulism are silly and credulous people, who have but little the matter with them, and that when they are seriously ill, they readily fly to the resources afforded by legitimate medicine. It is only fair to Dr. Inman to state, that, while he deprecates blood-letting in the majority of inflammatory affections, he admits its efficacy in those somewhat rare cases where the inflammation "is not produced by any poison, is sudden in its access, excessive in its intensity, extensive in its seat; where the patient has been in comparative health prior to its invasion, and has youth on his side; where the fever is severe, and where there is not time for other measures to be employed with a similar end in view." The use of mercury, antimonials, and blisters is, if not interdicted altogether, very much restricted by Dr. Inman, who likewise condemns starvation and low diet in the treatment of inflammation.

The second portion of Dr. Inman's work is devoted to the history of Atheroma in arteries, especially in connexion with aneurism and apoplexy. This deposit beneath the lining membrane of arteries is associated with the appearance of oil globules, and is a disease of degeneration. Dr. Inman states that in almost all the cases of phthisis which he has examined after death, he has found the aorta in the first or some advanced stage of atheroma; and he therefore regards atheroma as a species of tubercle in the arterial system. Now, as this condition is a frequent cause of apoplexy and of pulmonary hæmorrhage, it follows that measures of depletion must be injurious when the arteries are already weakened by degenerative disease, and that, on the other hand, tonic and invigorating treatment is calculated to improve the state of the arterial coats, and thereby to avert their rupture. Several cases are recorded in favour of these views, and, although they are not all very conclusive in support of his theory, they possess a considerable degree of interest.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### INFLUENCE OF PREGNANCY AND DELIVERY UPON INSANITY.

By M. MARCÉ.

M. Marcé thus concludes an interesting paper illustrated by cases. 1. We cannot protest too strongly against the practice of those physicians who advise or allow pregnancy in insane women, for it results from the facts mentioned in this paper that, in the great majority of cases, pregnancy and delivery, so far from exerting a favourable influence on insanity, seem, on the contrary, to hasten on the progress of the disease towards dementia. If in certain exceptional cases (2 in 16) pregnancy has suspended the progress of the disease, the improvement has been only temporary, and the insanity has re-appeared after delivery. 2. In some few cases (4 in 16), remarkable especially for the predominance of erotic symptoms, pregnancy has exerted a beneficial influence on the cure. 3. When insanity becomes developed during pregnancy,

it very often remains incurable, even after delivery, or is cured so long after that no influence can be attributed to the latter in the termination of the nervous affection. 4. Sometimes, however (3 in 10 cases), the disease disappears after delivery, and these cases must be regarded as sympathetic. 5. Delivery in the insane is often remarkable for the slight amount, or even complete absence, of pain.

*Annales Médico-Psychol.* tom. iii. pp. 359.

#### ON THE CARBONIC ACID GAS DOUCHE IN UTERINE DISEASE.

By M. CHARLES BERNARD.

Dr. Bernard reports very favourably of some trials he has made of Dr. Simpson's treatment of painful affections of the uterus by injections of carbonic acid gas. Of his successful cases he relates eight of the most marked, four being examples of advanced and very painful cancer, and four examples of engorgement or painful congestion of the cervix. The gas has been, however, employed in other cases in which no amelioration has attended its use, an aggravation of suffering being produced in one of them.

In all the patients, besides the local anæsthetic effect, more or less of general accidents were observed, these being usually very slight, but in one case so considerable as to compel the discontinuance of the remedy. They consisted in cephalalgia, giddiness, weakness, or confusion of vision, nausea, general lassitude, and more or less complete somnolence. After the third or fourth injection, the patient complains of cephalalgia, and especially of somnolence, these increasing day by day, but usually soon passing off, except a slight abiding headache. In the case in which these symptoms persisted, they entirely resembled those of incomplete asphyxia from carbonic acid gas. These symptoms are, no doubt, due to the absorption of the gas. The general conclusions, then, are—1. Injections of carbonic acid gas constitute a powerful anæsthetic, and cause a rapid diminution of pain in an engorged or cancerous state of the cervix uteri. 2. In one case they seemed to expedite the resolution of a simple engorgement, and in another, to diminish a cancerous ulceration. 3. But they sometimes give rise to general disturbances, which, scarcely noticeable in open cancer, are more or less marked in simple engorgement. —*Archives Gén.* tom. x. pp. 529—548.

#### ON METASTATIC HYDROCELE IN AFFECTIONS OF THE THROAT.

By M. VERNEUIL.

M. Verneuil only employs the term metastatic as a convenient means of indicating the sequence of events, without attaching to it any of the theoretical signification of the transport of morbid matter. He relates two instances of what he believes to be a newly-observed fact of the connexion of effusions in the tunica vaginalis with throat affection. In the first, a lad, aged 12, liable to affections of the tonsil, but otherwise healthy, became the subject of one of these attacks, but not of a severe character. By accident, he observed the scrotum to be large and heavy on the right side; but, as no pain existed, no notice was taken of it. After about three days, the affection of the throat terminated by resolution, as did the swelling of the scrotum three or four days later. Several attacks of angina occurred in succeeding years, and the youth always examined the scrotum, but never observed any reappearance of the swelling. At the period of puberty the right testicle was found to have remained soft, and less by a third, than that of the left side. When about 24, the young man contracted intense gonorrheal orchitis, which affected the right testis. Examined recently by M. Verneuil, the testis which twenty years before was the seat of effusion, was found to have continued soft and undeveloped. 2. A boy, aged 10, was admitted into the Children's Hospital with considerable swelling of the right side of the scrotum, which was at once found to be due to a hydrocele. This had appeared two or three days before, unpreceded by any local injury. On inquiry into the history of the case, it was found that ten days before the child had suffered from severe inflammation of the throat, the effects of which, indeed, were still observable in the altered character of the voice. Six or seven days after its appearance, the scrotum began to swell, and the affection of the throat got well. With more repose the effusion disappeared, leaving the testes of their normal size. The two cases bear much resemblance to each other, as they

do to cases of metastatic orchitis in mumps.—*Archives G n rales*, tom. x. p. 453.

## EXCERPTA MINORA.

*Treatment of Delirium Tremens.*—Dr. N ckel has found in six cases of delirium tremens the most remarkable advantage attend their treatment by prolonged (four to ten hours) tepid baths, at 91  Fah., together with cold applications or douches to the head. In most of the cases, however, small doses of opium or antimony were also required. Still the bath must be looked upon as the chief remedy, and valuable as enabling us to dispense with immoderate doses of opium, and by abbreviating the duration of the treatment. In two of the cases the bath had to be repeated.—*Froriep's Notizen*, 1857, vol. iii. No. 8.

*Cupping Blistered Surfaces.*—MM. Piorry and Favre have been recently making some successful experiments by leaving a blister on only for a few hours, and then applying cupping-glasses over it. In this way all mischievous effects of the blister may be avoided, and yet abundance of serum produced. The results will hereafter be published, thus much only being now stated to secure the priority of the practice.—*Gaz. des. H p.* No. 29.

*Restoration of Tarnished Silver.*—Sometimes silver instruments become so completely tarnished and discoloured that by no ordinary means can they be cleaned. Professor B ttger states that by electrolysis their colour is restored in an incredibly short period. For this a saturated solution of borax in water, or a moderately strong solution of caustic potash is to be brought into a state of active ebullition; and with this, the discoloured object laid in a zinc sieve-like vessel, is to be moistened. If a zinc seive be not at hand, we may attain the same end by touching the object, when it has been dipped in the boiling fluid, with a zinc rod.—*Buchner's Repertor.* 1857, p. 64.

*Insanity as observed in Prisons.*—M. Sauze, who is Medical officer to the Marseilles Lunatic Asylum, and to the cellular prison, thus concludes an interesting paper upon this subject:—1. The causes of insanity observed in prisons are usually independent of the imprisonment itself, whatever may be the system of this that is followed. 2. The insanity usually exists prior to the admission into the prison, and even before the trial. 3. When it becomes first developed in the prison, it is even then sometimes the result of causes foreign to the imprisonment. 4. Most of the causes of prison-insanity are inherent to the prisoner, not to the prison. 5. They especially consist in individual predispositions, such as hereditariness, imbecility, idiocy, epilepsy, former attacks, or a life of privation or debauchery. 6. Most striking analogies prevail between the insane, and a certain class of prisoners, consisting of persons of defective organization. 7. A certain proportion of prisoners would be more properly placed in asylums. 8. A considerable number of insane persons are condemned. 9. The cases of insanity which are manifested in prisons are not due alone to incarceration. They arise from various causes producing debility, and especially from an insufficient diet.—*Annales Medico-Psychol.* tome iii. p. 56.

*Curative effects of Pregnancy on Prolapsus Uteri.*—M. Brachet relates some cases in proof of the fact, that while the ordinary modes of treating prolapsus uteri by means of pessaries, abdominal belts, and the like, almost always fail, a cure may not infrequently be procured if the patient fall pregnant again, and then be confined to her bed for a period not less than forty days after delivery.—*Revue M d.* 1857, p. 546.

*Raw Meat in Dysentery.*—Dr. Weisse, of St. Petersburg, first in 1845 advised the employment of the lean of raw meat, very finely minced, in the chronic diarrh a of children, giving two teaspoonfuls four times a-day. Since then the same practice has often been extended to various forms of obstinate diarrh a with good effect. In the present paper, M. Pensa, now practising in Egypt, reports the benefit he has derived in several cases of severe dysentery occurring in the adults from the employment of raw, or nearly raw, minced meat, given in doses of from two to three ounces three times a-day.—*Ibid.* p. 336.

**EPIDEMIC OF DIPHTHERITIS.**—A terrible epidemic of diphtheritis prevails at the present time in several of the communes of the Department of the Yonne in France: and in spite of the means employed the mortality has assumed the most frightful proportions, children and young people alone forming the victims.

## GENERAL CORRESPONDENCE.

## PROVIDENT DISPENSARIES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have had so many applications for Rules for free Members, for "Self-supporting," "Provident," or "Victoria" Dispensaries, that I have thought it would be acceptable to your readers, to have them printed in your paper. At the same time my experience of failure leads me to observe that there has not been so much difficulty in inducing the poor people to join a Dispensary, as in establishing rules and regulations between the medical men; and until public opinion is brought to bear on this subject, it is not very likely to be otherwise. The Medical press can do much; and I beg to thank you for the encouragement that I have received since my last visit to London, and which I hope to be able to repeat during the summer, as I wish to have an opportunity of inoculating the Medical Students with the knowledge of the great advantages these institutions offer to them in particular.

## RULES FOR THE FREE MEMBERS.

1. The Free Members consist of working persons and servants, their wives and children, who are unable to pay for medical advice in the usual manner.

This rule must be occasionally modified by the committee in favour of aged, afflicted, solitary, or neglected members of the community, who may have a small income, but are incapacitated for any labour.

2. Any such person wishing to become a Free Member, must leave his or her name, age, residence, and occupation, at the Dispensary, and deposit one month's subscription.

The Medical Committee should meet weekly, and, in the commencement of the institution, daily to examine this list, and so prevent improper persons from becoming members; or they might depute this duty to some intelligent persons, to do it for them.

3. Every Free Member above 14 years of age shall pay one penny, and under that age, one halfpenny a week; except in a family consisting of more than two children, when one penny a week shall be considered sufficient for all under 14 years of age. Servants shall pay five shillings a-year, and in not less than half-yearly payments.

At the time the head of a family, or single person, is admitted, he shall declare the Medical gentleman that he intends to employ, and the Secretary shall place his name (ledger fashion) in that Surgeon's list, who by this list will be guided, and at the same time be furnished with an account by which he can judge of the remuneration he is to receive. This plan will be found far better than being paid per case, for crafty and greedy persons can multiply cases, or, what has been as bad, be suspected of doing so.

4. The payments of the Free Members shall be made in advance. No one will be entitled to the benefits of the Institution if in arrear, and each family shall pay a fine of one penny for the arrear of every week. If any Member shall be more than four weeks in arrear, his or her name shall be erased from the books.

The payments should be brought by the parties with their tickets to the Dispensary at an appointed hour, once a week; or if the number of Free Members should exceed two thousand, the time for receiving the money should be extended, and more hours appointed for names beginning with certain letters—for instance:—

Names from letter A to G, from two to three o'clock every Thursday afternoon.

Names from G to S inclusive, from three to four o'clock every Thursday afternoon.

From S to Z from four to six o'clock every Thursday afternoon; and this should be on the cards of these letters respectively, so as to afford no excuse for procrastination or idleness.

The fines should be always strictly enforced, and should be applied to assist the midwifery or convalescent fund; for these purposes they will be paid with comparative good humour.

And if the Free Members pay fines for non-attendance (I

beg to take this opportunity of stating that) Medical men should be fined if they do not attend at their appointed hours, or send a qualified substitute. It has happened that Medical officers receiving very large sums from these people will keep them waiting for an hour or more. There is no excuse for this neglect; use them fairly; their time is money; and he, let his rank be what it may, who keeps a working man or woman unnecessarily waiting for a minute, is unrighteous and unjust, and should be made to pay for it—say half-a-crown for every five minutes he is behind his appointed time.

5. Benefit Societies will be received as subscribers to the Dispensary, and their members entitled to all the benefits of the Institution. The rate of subscription shall be shillings a-year for each member. The payments to be made by the stewards quarterly, and in advance.

By this rule the members of a Benefit Society would have the choice of a Surgeon, which they have not now; their contract is frequently with one man, and consequently he becomes more careful to cultivate the friendship of the stewards, or landlord of the "Red Lion" or "Black Bull," than the great mass of the Society.

It might hereafter become a question whether the Medical Committee, on examination of the lists of a Benefit Society, would not find many persons in it that the Dispensary ought not to embrace, and which, after a time, might with great justice and propriety be excluded.

6. No one actually labouring under sickness can be admitted a Free Member unless two healthy persons above 14 years old enter at the same time, and each pay the whole year's subscription in advance. Any such person unable to procure two others to enter with him shall, by paying ten shillings, be entitled to the privileges of a Free Member for three months; and may afterwards continue a Member by paying the usual rate of subscription.

This rule is quite necessary; be careful to exact the ten shillings. I have known this admission-money amount to £80 per annum; and if they neglect to pay their weekly pence for above a fixed time, exact it again and again; for when the cost of Medical advice is made so low as to leave few or none with an excuse for not paying it. The only way is to force them to be provident by fining neglect and improvidence.

7. If any Free Member shall be discovered by the Committee to be ineligible to the benefits of the Institution, his or her name shall be erased from the books.

It will happen that many persons are eligible to become Members at one time that are not so afterwards; for there are many excellent persons, when defended from the ruinous expenses of sickness, will accumulate property so fast (or they may have it bequeathed to them), as to become improper persons to belong to the Dispensary. I have known such, who, when the necessity of putting them away had been properly explained to them, thanked the Committee for what the Institution had done for them, and begged to present it with a guinea as a mark of their respect.

8. Every Free Member shall have the choice of whichever Surgeon he may prefer; but it will be expected that he do not change his Medical attendant during his illness. He may have a consultation of the Medical officers, if it be thought advisable.

The free member made his choice when he entered and enrolled himself, but his Medical attendant may, as he thinks, have become cold and indifferent, or unsuccessful with him,—from increasing independence or advancing years. Whatever may be the cause, any member shall be at liberty to change his attendant, and notify his proposed change to the Secretary, who will make the alteration in the ledger list of the Medical men accordingly.

9. Those patients who are able to do so, must attend at the Dispensary between and in the morning, bringing their admission ticket at the first visit, and afterwards their prescription paper. Those who are too ill to attend at the Dispensary, must send their tickets before eight o'clock in the morning, to the Surgeon at his house, whom they wish to call upon them, and he will visit them at their own homes. In cases of accident or sudden illness, they can have the attendance of either of the Surgeons, on sending their ticket to his residence.

In no case should patients be attended either at their own homes, or at the residence of the Medical man, excepting when too ill to come to the Dispensary—the saving of labour, and the

annoyance of continual interruption for want of a common place to meet patients, is excessive.

In a large Dispensary there might be three or four Surgeon's rooms, and several Surgeons to each room, who by coming at different hours, could accommodate with great ease any amount of patients.

10. No Free Member will be visited at his own home, if he reside beyond one mile from the institution.

This rule is made in reference to towns, but the committee may alter it, and allow a certain mileage to be agreed upon—according to the usual rate in their respective neighbourhoods.

When dispensaries become general, it may be as well for them not to encroach on each other's district, indeed, the labour of each Medical officer would be much lessened if they were to divide a district into as many sections as there were Surgeons, and each one keep in some degree to his own section, by preferring to cultivate his practice in that section, but not to withdraw from any one, who may choose to select him even in another's walk. Medical men could then do double the real business with half the labour.

11. Any married free member, being pregnant, may have the attendance of whichever Surgeon she may prefer, on depositing at the Dispensary 10s. 6d., one month before her expected confinement.

The forfeits for non-payment by the Free Members, or for Medical men who do not keep their appointed time at the Dispensary, may go in aid of this fund, and either lessen the fee to the poor woman, or increase it to the Medical man—because wages and the expenses of living are so different in various parts of the country, so that the same ready-money fee, which is satisfactory in one part of the kingdom, is not so at another; and no people in the world are more amenable to the feeling of what is due to the Medical man than the poor are. Only bring the Profession within their means, and there is no want of liberality among them; the real absence of liberality and generosity is amongst those who love to be cheaply and profligately benevolent, at the sacrifice and cost of the highest skilled labourers in the world.

12. When considered necessary by the medical gentlemen, linen will be lent, and cordials, broth, and other comforts given to the Free Members by the Ladies' Committee.

Although a "Provident," "Self-supporting Dispensary," or "Victoria Dispensary," it will be proper to have a Ladies' Committee for the distributing of such funds as the friends of the industrious and working poor might provide for them in sickness.

These ladies might have voluntary or even paid almoners for the careful distribution, under the written orders of Medical men, of linen, sago, meat, special nurses, etc., and supply them with discrimination and judgment that experience would soon give them; and there are many thousands of rich, aged, neglected, and solitary women that would be brought from the fields of dead faith into practical, persevering works of charity highly advantageous to their own soul's health as well as that of the bodies of their neighbours; and many young women also who would find an honourable employment in a variety of kind offices among the afflicted—more congenial to their best feelings than the waste labour in which they commonly spend their days.

It may be asked, Where are the convalescent funds to come from? Answer: In proportion as these "Self-supporting," or "Victoria Dispensaries," superseded the old honorary ones, the money now given to them might be turned into this channel.

13. Patients must find their own bottles, bandages, etc.

The dispenser should also keep a small stock by him—so that if a person brought one of a different size from that required, it might be changed without much trouble.

14. The children of Free Members, and of all poor persons, may be vaccinated, gratis, on any Wednesday or Thursday morning at eleven o'clock.

The vaccination should be done by the dispenser, at some fixed months in the year in the spring and autumn, notice of which should be suspended in the general waiting room, and the women confined during the past year should have a printed notice sent to them, that they may bring their babes to be vaccinated.

15. Medical men will attend at the Dispensary every day, except Sunday, in the following order:—

## Room No. 1.

- Mr. A. every Monday, Wednesday, and Friday, from 10 to 11 o'clock.  
 „ B. every Monday, Wednesday, and Friday, from 11 to 12 o'clock.  
 „ C. every Monday, Wednesday, and Friday, from 1 to 2 o'clock.  
 „ D. every Tuesday, Thursday, and Saturday, from 10 to 11 o'clock.  
 „ E. every Tuesday, Thursday, and Saturday, from 1 to 2 o'clock in the afternoon.  
 „ F. The same, from 2 to 3 o'clock.  
 „ G. The same, from 3 to 4 o'clock.

## Room No. 2.

- „ H. And by repetition, any number of Medical Officers could be brought into use by having separate rooms for eight or ten each in the same building.

There should be a Dispensary of this kind for every 100,000 of your population, or about two in each of your postal divisions.

There are 30,000 proper persons to belong to it in each 100,000, whom you seduce for the pawnbroker and the gin-palace, and train for the workhouse and the gaol, because you will not condescend to do that for their humble estate (for their health is their estate) which you do for your own property when you insure your house from fire.

Only give the working people a chance of providing for themselves, and they will discontinue to ask for Hospital outpatient tickets or Dispensary tickets.

In the hope that I have pioneered the way for a plant that will take root deeply downwards in the hearts of the people, and bear fruit upwards of patriotism, loyalty, and goodwill, mercy, justice, and truth, I am, &c. H. L. SMITH.

Southam, March 29, 1858.

## ON IRIDECTOMY.

[To the Editor of the Medical Times and Gazette.]

SIR,—History abundantly demonstrates the fact that the usual lot of any proposed alteration, be it improvement or not, is to be treated in a careless or contemptuous manner on its first promulgation. It is asserted to be old, or its value is denied: hereafter it reappears,—if true, becoming gradually admitted; if false, being decisively condemned. Such in our science has been the case with lithotomy, herniotomy, etc. in former days; and with iodine injections, the whole subject of diseased joints, especially in regard to excisions, the treatment of internal obstructions, etc. in our own day.

Such appears to be nearly always the inevitable fate, and I suppose Dr. von Graefe's proposal must submit to the same treatment. But in the present case things bear a somewhat darker aspect. Men, hitherto favourably known, have published a paper in which from beginning to end the subject of iridectomy is discussed in an unfair spirit: no new facts are added; the reasons and facts adduced by Graefe are in general omitted, while hypothetical reasoning and dicta of the authors are opposed in a contemptuous and bombastic manner to careful observations and to deductions from protracted investigations.

Whether Graefe's ideas and methods of treatment should ultimately be admitted or not will depend, not on the mere assertions of this or that man, but on experience—on careful, long-continued, written experience.

It seems to me that this determination will be best promoted by the publication of Graefe's own papers, on the translation of which I have been for some time engaged; and hence, I shall not in the present paper defend Graefe's opinions. I shall simply endeavour to show that Messrs. Mackenzie and Jones have entirely failed in their attack.

The first question is, Do the recurrences of iritis principally depend on synechia posterior or not? Graefe asserts (a) in proof of the affirmative, that iritis, cured without posterior synechia, rarely recurs; that with slight synechia, occasionally only; that with multiple and broad synechia, generally; and that with synechia posterior totalis, almost without ex-

ception. This is shown by the comparison of two eyes, one with and the other without synechia, etc. etc. Now these are or are not facts, and cannot be refuted by "it seems to us that this is a very perverted view of the matter. We consider, etc."

Their assertion that Dr. Graefe's application of the ordinary treatment is unskilful is, to say the least, rather cool; their only authority being apparently Dr. Quadri; and they ought to have known that that gentleman's extreme accuracy, etc. had been already sufficiently exposed by Sperino and Paoli (b).

Graefe asserts, in favour of his opinion, that the ciliary pains often depend on posterior synechia; that they disappear as the pupil dilates, and again make their appearance as it contracts, and this when there are no inflammatory symptoms present (A. f. O. Bk. ii. 2. S. 205). This explanation is entirely omitted by our authors.

After all, we find near the end of the same column, that they "do not mean to say that the adhesions of synechia posterior contribute nothing to the relapse, etc." which looks as if they were not very certain of what they were saying.

In the case (at the commencement of the next column) they have omitted from the ultimate result that he became capable of reading small print (No. 4 of Jäger's specimens), and that, without using any medicines, he has not been again attacked by iritis, etc. This would, I think, be generally considered very successful.

As to the statement (near the end of the second column, p. 343), that "these are cases in which the sight being still good, it would be better, perhaps, not to interfere at all," we need merely remark, that Graefe's practice is founded on the fact previously asserted, that in total synechia posterior recurrence is almost infallible; the remarks (at the upper part of the first column, p. 344) are equally to the point, and equally valuable.

Lower down in the same column are some remarks on paracentesis, which only deserve notice as demonstrating the general spirit of the article.

In the note (same column), they state the designation of linear extraction to be unnecessary; such a statement, I suspect, will not be admitted, even on their authority, without some further reason.

I have now discussed all the criticisms referring to the paper on Iridectomy in iritis and irido-choroiditis, and hope that I have sufficiently shown that mere assertions have been opposed to facts, and that this paper is not only valueless, but even mischievous in its tendency.

As much might be urged in reference to the case from the paper on Sympathetic Affections, and to Iridectomy in Glaucoma. Should it be necessary, I will at some future time enter on these subjects.

I am, &c.

THOMAS WINDSOR,  
Senior Assistant-Surgeon, Manchester  
Eye Hospital.

## NITRO-GLYCERINE.

[To the Editor of the Medical Times and Gazette.]

SIR,—Calling on my brother a few days ago, I found him experimenting with glonoin, a new drug, of which I had previously heard nothing. He wished me to take a small dose, as he had done so himself without any very disagreeable effect. I refused; but, on visiting him the next day, he renewed his request, observing, "Why your Professor, Dr. Harley, says he has taken 199½ drops of a solution equal to this in less than an hour." I then saw my brother take one minim, and in half an hour, as no serious effect followed, after counting my pulse, which was eighty, I took the same dose. We now purposely changed the subject of conversation. In the course of a few minutes I exclaimed, "I feel drunk." This sensation was quickly followed up by a dull aching pain at the back of my head, which was alternately better and worse, each accession becoming more and more severe. It soon extended to the forehead and the back of the neck, in which

(b) Dr. Mackenzie (last edition) says at page 534, in speaking of the sequelæ of iritis, "adhesion to the capsule of the lens (synechia posterior), is very common. The best directed treatment may sometimes fail in preventing these disastrous results."

there was a decided feeling of stiffness. I also experienced some difficulty of deglutition, succeeded by nausea, retching, and flatulence. A profuse perspiration ensued, and in a quarter of an hour the symptoms began to abate, but I continued dull and heavy. My pulse was now 100. Considerable headache remained, which increased in the after part of the day to such an extent that at six o'clock I was compelled to go to bed. At break of day I was not relieved, but after a few hours more sleep I arose in my usual health. I have only to add that I made this brief sketch of my own feelings before reading the contradictory statements which have appeared in your columns.

I am, &c., F. AUGUSTUS JAMES.

University College, April 5, 1858.

[To the Editor of the Medical Times and Gazette.]

SIR,—The existence of any fact once established cannot be affected by a subsequent discovery; and though the evidence may at first sight be conflicting in the two cases, and apparently tending to a precisely opposite conclusion, it is often within the scope of reason to reconcile seemingly contradictory testimony.

Gmelin has stated that half a drop of pure glonoine would kill a man.

In my last paper on this subject, I stated that two drops of what the Homœopaths call the first dilution of glonoine, produced profound coma in me. Doctors Fuller and Harley took very much larger quantities, and produced nothing beyond a headache. Was the action of the drug less powerful in their cases from peculiarities in the subjects of the experiment, in the substance experimented with, or the conditions under which the experiments were made? Putting aside for the present the hypothesis that idiosyncrasy may greatly influence the action of such an agent as glonoine, I think a very reasonable explanation may be found in the great variation in strength to which glonoine is liable, at which we cannot wonder when its mode of preparation is considered. But a far more important cause in determining the extent of its action is to be found in the conditions under which the drug is taken.

In my own case my nervous energy had been much impaired by a hard day's work; for contrary to my usual custom I had walked to all my patients that day, and besides this I had just finished a painful and protracted surgical operation, involving as it did a considerable expenditure of nervous force, added to which the hour had arrived when there was a natural tendency in the brain to subside into that state of unconsciousness in which one-quarter of its life is passed. I have since taken the same quantity of glonoine under different conditions, with no other result than the production of a mere headache.

Having in my experiments on myself experienced the greatest variation in the strength of different specimens of glonoine, I was disposed to think, when I read Dr. Fuller's and Dr. Harley's experiments, that they had used a less powerful agent. I therefore called on Dr. Fuller in the morning of April 3, and requested him to take a part of the same glonoine which had affected me. He kindly acceded to my request, but to my surprise he experienced little besides the usual headache, which appears always to result from a small dose.

From Dr. Fuller's I went to a London Hospital, where I heard a patient was undergoing treatment with solution of glonoine for hemicrania; he had been taking one dose of two drops daily, but the medicine had produced no effect on him. I took two drops of his solution, and was but slightly affected by it. By permission of his Physician I gave this patient two drops of my own solution. In about a minute he became pallid, felt sick and giddy, his forehead was covered with perspiration, and he sank on to the bed by which he was standing almost unconscious, his pulse failing so as scarcely to be felt. I requested that he might have some stimulant, and after taking a little ammonia the circulation became more vigorous, and I left him in twenty minutes with a marked diminution of his pain, and he expressed a great desire to sleep, a luxury which his sufferings had almost deprived him of the previous nights.

The slight action of glonoine on Dr. Fuller, who was in vigorous health and not suffering from fatigue at the time he took the dose, and the powerful effect produced on the hospital

patient, whose nervous energy was reduced by suffering and want of sleep, affords a good illustration of the explanation which I have ventured to give of the apparently opposite results which have been observed.

Some pure glonoine was procured from Morson's, in Southampton-row; this was one hundred times stronger than that, two drops of which produced so powerful an effect on me. One drop of this pure glonoine was given to a mouse, and larger quantities to a calf, cats, and rabbits, without producing any appreciable effect, thereby confirming the conclusion before arrived at that not the glonoine, but the spirit in which it was dissolved, had affected the animals which died in the former experiments.

The curious fact of certain poisons exerting a powerful influence over some animal systems, while harmless to others, is not without analogy. It is stated on good authority by a recent writer that the horse can with safety eat aconite, the goat hemlock, and the rabbit belladonna; and Dr. Livingstone mentions a small African insect, the tsetse, whose bite is fatal to the horse, ox, and dog, but affects man in only a very trifling degree.

My friend, Mr. Lawrence, Surgeon, of Brighton, slightly moistened the tip of his finger with the solution of glonoine (1 per cent.) and applied it to his tongue; he took only just sufficient to taste the fluid. In about three minutes he experienced a "muddled" sensation in his head, and felt as if he could easily have gone to sleep in the operating room, where we then were; he believes that had he taken a little more he must have fallen asleep; his appetite failed for the rest of the day, and he passed a restless night. Mr. Lawrence regards the effect produced on him as the more remarkable that he has very little susceptibility to the influence of the common narcotic drugs.

Case 5.—G. F., aged 24, epileptic eight years. After a fit on the 4th of March, he slept nearly an hour, and then awoke in a state of violent mania, struggling with such violence that it was with difficulty two persons could keep him in bed; with eyeballs projecting, and mouth half opened, he looked as if he were contemplating some afflicting sight, while he rapidly reiterated an unmeaning monosyllable, doc-doe-doe, in a painfully plaintive tone. In this state I was called to attend Mr. F. I touched his tongue with a cork moistened with solution of glonoine, and after the third application his struggles ceased, and he sunk into a tranquil sleep, from which he awoke refreshed and well the next morning.

In this case the rapidly acting sedative influence of the medicine was most marked, and the exceedingly small dose required made it peculiarly valuable, as no bulky remedy could have been taken owing to the excited condition of the patient.

Case 6.—Mrs. R. sent for me in the night of March 17, on account of severe neuralgic pain in the lower part of the cervical region of her spine and right arm. Her sufferings had been severe for some hours, and still continued, when I applied less than a drop of glonoine solution to her tongue. In a short time this patient complained of a peculiar pain and pulsation in her head; she became drowsy, and buried her head in the pillow, but retained sufficient consciousness to request I would not leave her while she felt "so strange." These effects lasted about ten minutes, during which she had several attacks of general rigor, which were succeeded by nausea and coldness of the extremities; but the neuralgic pain was quite subdued for a time, though it returned in a much smaller degree.

Case 7.—Mrs. L., aged 28, weak from undue lactation and neglect of air and exercise, consulted me, March 22, on account of supra-orbital neuralgia, from which she had suffered more than a week; the pain usually commenced at six o'clock in the morning, and continued till eleven or twelve. A quarter of a drop of solution of glonoine was given, and the pain ceased for that day almost immediately. She recovered in a few days under appropriate treatment.

Case 8.—Mrs. D., aged 38, under treatment for dyspepsia. March 29, she complained of severe hemicrania, which had troubled her for many days. She took about a drop of solution of glonoine in perfect ignorance of any effect it was likely to produce. In a minute or so, she reclined on a sofa to save her from falling, put her hand to her forehead where she experienced a pulsating pain. In a few minutes more her head was free from pain of any kind, and there had been no return two days after.

**Case 9.**—Miss V., aged 28, frequently suffered severely from what she calls nervous headaches; these she has been in the habit of curing with Indian hemp. On the 1st of April, a violent headache was suddenly produced by a fright caused by her horse; she was kept awake nearly all night, and the following morning she requested me to give her something for the pain, which continued severe. Her old remedy had been discontinued by my advice. I applied a small quantity of the dilution of glonoine to the tip of her tongue, which produced scarcely any effect. Two drops were then given, and in about a minute she became giddy, and said it is just like taking chloroform; she lay back in a chair, supporting her forehead with her hand, trembled, and said faintly that her feet were cold: her pulse rose to 100—before it was 80. In about two minutes she recovered, complained of great tightness at the root of the neck, which soon subsided. Her headache was gone; and in half-an-hour she left my house feeling unusually well and “bright,” as she expressed it.

Forcibly struck by the slight effect produced in the last two cases by what, from my former experience, I should have considered a powerful dose, I myself took two drops of the solution, and only experienced a sense of fulness and throbbing in the head; my pulse rose twenty in the minute. The experiment was repeated on a married lady, aged 32, with a similar result. The cases 8 and 9 had been treated with a fresh specimen of the glonoine.

From what has been observed it would appear that glonoine is liable to great variation in strength. That under ordinary circumstances of health and vigour it may be taken in small quantities with safety, but that when the nervous energy is much diminished by fatigue or suffering it may act with the greatest power.

It affords me great satisfaction to find the action of nitro-glycerine has engaged the attention of those who are so much more capable than I am of doing justice to the subject; and I hope that we shall soon be furnished with more precise information on this curious medicine.

I am, &c. A. G. FIELD, F.R.C.S.  
Old Steine, Brighton.

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, MARCH 23, 1858.

Sir C. LOCOCK, Bart., President, in the Chair.

#### A paper by Mr. TOYNBEE was read on ANCHYLOSIS OF THE STAPEDIO-VESTIBULAR ARTICULATION,

(THE BASE OF THE STAPES AND THE FENESTRA OVALIS) ASSOCIATED WITH RHEUMATISM AND GOUT; WITH AN ACCOUNT OF 136 DISSECTIONS OF THE DISEASE.

The author commences his paper by showing that there is a distinct joint between the circumference of the base of the stapes and the inner surface of the fenestra ovalis, and that this stapedio-vestibular joint (perhaps more constantly used than any other in the human body) is very subject to be affected with rheumatic gout, (rheumatic arthritis,) producing in various stages of its progress various degrees of deafness. For the better elucidation of the nature and treatment of rheumatic arthritis in the stapedio-vestibular articulation, the author commences by making some general observations upon the subject of rheumatism and gout, the results of which may be thus briefly stated. He considers the poisons of gout and rheumatism to be thus far identical in their nature that they both consist of an excess of the nitrogenous element of the blood, and that this nitrogenous element in the case of rheumatism is fibrine, and in that of gout albumen. The view that the element in the blood causing rheumatism is fibrine in excess, is supported by the following facts:—1. That this fibrine is found in so great excess in the blood of rheumatic patients, that Lehmann asserts that of all diseases the fibrine is in general increased in the largest proportion in acute articular rheumatism

and pneumonia. 2. That this excess of fibrine also manifests itself by the excess of urates eliminated from the blood in patients with the so-called rheumatic diathesis. 3. That attacks of acute rheumatism come on contemporaneously with the inability of the system to use the excess of fibrine in the blood, and to eliminate the excrementitious urates. 4. The attack of rheumatism is produced by any cause which prevents the conversion of the fibrine of the blood into the fibrous elements of muscles and other fibrous organs, and the due elimination of the urates. 5. In cases of acute rheumatism the excess of fibrine in the blood finds an outlet in fibrinous effusions, while in chronic rheumatism it finds an outlet in hypertrophy of the fibrous structures. 6. All curative measures for rheumatism do good in proportion as they cause the excess of fibrine to be eliminated in the form of urates or consumed in the process of assimilation. 7. All preventive measures in rheumatism consist in the use of dietetic or other hygienic rules, whereby the entrance of an excess of fibrine into the blood is prevented, or when it is introduced that it may be assimilated, and the effete matter eliminated as urates. That the nitrogenous element in the blood which causes gout is albumen in excess, is indicated by the following facts:—1. Whether known to us as globuline, gelatine, chardine, gluten, etc., the textures containing albumen are those implicated in gout. These textures may be divided into four classes; as the blood cells containing globulin, the cellular, mucous, and purely serous membranes containing gelatine, the cartilages containing chardine, and the cartilage of bone, gluten. 2. That globulin, the coagulable matter of the blood-cells, is more abundant in plethoric gout, and that one source of the increased quantity of uric acid in the blood of some gouty patients may be ascribed to the increased quantity of globulin in the blood. 3. The food inducing an attack of gout is usually peculiarly rich in albumen. The analogies and differences between gout and rheumatism are thus presented in a tabular view:—

#### GOUT.

##### CAUSES.

1. *Predisposing.*—An excess of the nitrogenous element of the blood, probably albumen, from the use of too highly nitrogenous, or from mal-assimilated food.
2. *Exciting.*—The sudden addition to the blood of so large a quantity of albumen, that it can no longer be assimilated, and becomes a poison; or any circumstance, as fatigue, which prevents this assimilation, and consequently the elimination of the urates. The effort to rid the system of all poison constitutes the attack of gout.

#### RHEUMATISM.

##### CAUSES.

1. *Predisposing.*—An excess of the nitrogenous element of the blood, probably fibrine, from the use of too highly nitrogenous, or from mal-assimilated blood.
2. *Exciting.*—The sudden addition in the blood of a large quantity of this element, or any circumstance, as the application of cold, which prevents the assimilation of the element, and the elimination of the urates. The violent effort made to rid the system of the poison constitutes attack of acute rheumatism.

##### SEAT.

- |                   |   |  |
|-------------------|---|--|
| Fibrous<br>Tissue | { | 1. <i>Muscular Fibre.</i>  |
|                   |   | 2. <i>Hard fibrous tissues.</i> —As tendons, aponeuroses, fibrous visceral envelopes, as the fibrous layer of dura mater, pericardium, synovial, and other serous membranes. |

The author then shows that in the disease properly called rheumatic gout, both fibrous and vesicular, otherwise named fibrinous, and albuminous, structures, are affected, and he is thus led to consider the diseases of the stapedio-vestibular articulation, in which both fibrous and vesicular structures are affected, as constituting what is called ordinarily rheumatic arthritis, or rheumatic gout. The author then pro-

ceeds thus to describe and classify the 136 dissections laid before the Society, of rheumatic gout causing ankylosis in the stapedio-vestibular articulation.

In 49 cases there was simple expansion of the articulating border of the base of the stapes; in 29 there was expansion of the articular border of the base of the stapes, with calcareous whiteness; in 25 there was expansion of the whole of the base, and effused bone connecting it to the vestibule; in 21 there was osseous matter effused between the stapes and the fenestra ovalis, producing simple ankylosis; in 12 there was osseous matter effused around the fenestra ovalis. In addition to the above 136 specimens of bony ankylosis, the author alludes to 53 dissections of membranous ankylosis, the particulars of which had been previously laid before the Society; in the latter cases the ligaments of the stapedio-vestibular articulation had become more rigid than natural. The author states that rigidity of the ligaments, which is the usual morbid condition in cases of deafness in advancing years, may, as a general rule, be diminished.

In speaking of the diagnosis of the disease, the author states that there is usually what is called the uric-acid diathesis. Frequently the patient has had an attack of rheumatism, gout, or rheumatic gout, but the only symptom in the ear is gradually increasing dulness of hearing, usually worse during a cold, the adapting power of the ear being the first to be diminished. There is usually an absence of the distressing noises present in debility of the nervous apparatus of the ear. The mucous membrane of the fauces and nose is congested and tumefied, the membranous meatus auditorius is also red, and often tumefied. The osseous walls frequently present rounded bulgings. The membrana tympani is often opaque and dull on its surface. Respecting the prognosis.—If the ligaments only are affected, as they are in the earlier stages of the disease, or if the circumference of the base of the stapes be merely slightly expanded, considerable benefit may be obtained by persevering treatment. This treatment consists in the use of general remedies, whereby the poison of rheumatism and gout is removed from the blood, and in the local application of counter-irritants. In the later stages of the disease, when bony ankylosis has taken place, no benefit can be attained further than the removal of the symptoms arising from congestion. The paper concludes with a recital of cases illustrative of the disease, with details of the pathological conditions found in some upon dissection.

Mr. HARVEY said he thought Mr. Toynbee had rather thrown confusion over the pathology of rheumatism and gout than cleared away any of its difficulties, and had misunderstood Dr. Garrod's opinions. He should be glad to be informed whether Mr. Toynbee had dissected the specimens on the table from both sides of the head, or whether they had been taken indiscriminately. If the former, it confirmed his opinion, and, he conceived, settled the question that deafness from rheumatic arthritis affecting the ears was one of a constitutional or blood character. In his (Mr. Harvey's) dissections both sides were alike affected, though not always to the same extent; hence he had for years adopted a constitutional treatment, rarely finding any benefit to arise from local applications or counter-irritants. He was surprised to hear that the disease so often produced ankylosis of the stapes, and was therefore disposed to believe that many of the specimens produced must have been taken from senile people. He believed the disease occurred chiefly in the middle period of life, and that, if diagnosed rightly and treated judiciously, was susceptible of great relief, and often a complete cure. The investigation was of the highest importance; it would bring into the category of curable disease many so-called cases of nervous deafness, which had been mistaken for this arthritic condition of the ears. He should be glad to know whether Mr. Toynbee had anything to suggest as to the physical appearances that might be pathognomonic of the affection in question. He (Mr. Harvey) had suggested an opinion some time since that he thought might explain the appearances so often seen in such cases, such as the concavity of the membrana tympani, the bold relief of the ossicle, and sometimes its deviation. It was well known that before the ear became the seat of the mischief the fauces and Eustachian passage were for some time affected; and remembering the distribution of the sympathetic nerves, and the course and insertion of the tensor tympani muscle, the reason for the changes in question became obvious, and it explained the

frequency of the neuralgic seizures, and of the tinnitus which so often distressed patients suffering from the disease.

Dr. MERYON thought the paper was interesting and suggestive, indicating, as it did, the liability of the stapedio-vestibular joint to rheumatism. He questioned the correctness of the author's views respecting the identity of gout and rheumatism. He had failed to produce either by the introduction of highly nitrogenized articles into the blood. With regard to senile deafness, he believed it was more dependent upon a drying up of the fluid than upon a bony deposit in the stapedio-vestibular articulation.

Dr. GARROD said the subject was one to which he had not paid much attention, but as his own researches into the nature and treatment of gout and rheumatism had been mentioned by the author, and his (Dr. Garrod's) opinion mis-stated, he felt compelled to rise and show the error of much of the author's pathology. Mr. Toynbee had come to the conclusion that gout and rheumatism were identical in their nature, and had sought to make the Society believe that his (Dr. Garrod's) researches tended to favour that view. He had arrived at an entirely different conclusion, and his inquiries were undertaken without any previous bias. Some of the most striking phenomena resulting from gout were certain changes in the articulations and other structures, consisting in the deposit of a peculiar matter, the urate of soda, in a beautifully crystalline form. This was seen within the substance of the articular cartilages, in the ligaments, the tendons and their sheaths, also on external parts, giving rise to tophaceous deposits, or the so-called chalk-stone. Such concretions were peculiar to gouty patients, and he was convinced were never the result of any other disease. In every case in which he had seen them the affection was undoubtedly of a true gouty character, and had originally commenced as a mono-articular inflammation of the metatarso-phalangeal joint, or ball of the great toe. As such structural changes were never produced by, or were the result of true rheumatism, he thought this alone formed a distinguishing or diagnostic mark between the two diseases. The difference between them was equally evident on an examination of the blood. The many examinations of the fluid referred to by the author, he (Dr. Garrod) had divided into two classes, those connected with articular disease and those not so connected. In regard to the former, uric acid was present in large or abnormal quantities, determined either by quantitative analysis or by crystallization upon a fibre from the acidulated serum in all those cases of disease originating in a great-toe affection, and accompanied by deposits or other symptoms, which would leave no doubt as to its genuine gouty character; whereas, in all cases of true rheumatism, such as rheumatic fever with pericardiac or endocardiac inflammation, or the chronic conditions arising from such, and also in the articular cases connected with urethral disease, no uric acid had been discovered. He therefore regarded the absence of uric acid in the blood as proof that no gouty character existed. He had never seen acute inflammation of the pericardium or endocardium in acute gout, although he was aware that chronic valvular affections were often met with in gouty subjects, but it must be remembered that the predisposing and exciting causes of the slow alterations in the structures about the heart were also those which most frequently give rise to gout. He alluded to the different kinds of alcoholic fluids, and especially to wine and malt liquors, when taken in large quantities. He differed from Mr. Toynbee as to the similarity of character in the urine in cases of gout and rheumatism. The elimination of uric acid by gouty patients was much below the average; but Mr. Toynbee had assumed the contrary. The passing of urates in large quantities was far from showing that the acid existed in abnormal amounts in the blood; indeed, it indicated the probability of the contrary condition, for freedom of excretion by the kidneys was not compatible with retention in the blood; and the large elimination of urates was not confined to rheumatism, but was found equally in affections of the liver, spleen, and other organs. The two diseases were also entirely distinguished by other characteristics, as well as by their different predisposing causes. Gout was more common in males, and after the age of thirty strongly hereditary in character, and induced by good living; whereas, rheumatism was seen in the most characteristic forms most frequently amongst females, and generally in the young. The hereditary predisposition was not so strongly marked; it was caused by exposure to cold, especially in the weak and ill-nourished. He had on a

former occasion brought forward cases to show that in hospital practice nearly twenty-five of his gouty patients had previously been subject to the influence of lead, and nearly all of them had experienced the common symptoms of such metallic impregnation; the lead poisoning, however, never induced rheumatic fever. He was somewhat disappointed from the author not having clearly shown any relation between the diseases of whose pathology he had treated and the various specimens exhibited; for it had not been proved that the alterations had been produced either by gout or rheumatism, and no analysis of the deposits had been given, indicating the presence or absence of uric acid. The author had referred to Dr. Adams's researches on the alterations recurring in the so-called chronic rheumatic arthritis, but though Dr. Adams employed the term rheumatic gout, he nevertheless admitted that the disease inducing such alteration in the joints shown by the absorption of the cartilages, and the eburnation of the heads of the bones, was in no way allied to gout, and was only so far connected with rheumatism as in a certain number of cases the latter affection appeared to have acted as an exciting cause of the peculiar local disease.

Mr. TOYNBEE, in reply, maintained the correctness of his views. One of the specimens before the Society, he said, was taken before the age of twenty, from a girl who had died in St. Mary's Hospital.

The Society then adjourned.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, MARCH 18, 1858.

DR. SIEVEKING, Vice-President, in the Chair.

### FALLOPIAN DROPSY.

DR. PRIESTLEY exhibited the fluid from a Fallopian dropsy. The case was that of a lady who was supposed to be suffering from retroflexion of the uterus. Dr. Priestley found, on examination, that there were two tumours behind the uterus, one of which, of a spindle-shape, was the Fallopian tube distended with fluid; the other an ovarian tumour. Great discomfort was experienced by the patient after walking, the enlarged Fallopian tube becoming impacted behind the uterus. A small canula and trochar was passed into the tumour through the upper part of the vagina, and the fluid drawn off. The patient did well.

### MR. HENRY THOMPSON read a paper on THE DIAGNOSIS AND TREATMENT OF SYPHILIS IN ITS PRIMARY FORMS.

Mr. Thompson commenced by demonstrating the importance of deciding promptly upon the nature of the primary forms of syphilis in relation to treatment and prognosis. He stated that our knowledge of syphilis has greatly advanced during the last few years, thanks to numerous observers in this country and abroad; but that to Ricord the merit is pre-eminently due of having defined the great laws which its phenomena exhibit. Without giving his adhesion in every respect to all the dicta of that illustrious observer, the author of the paper asserted that a careful examination of the subject compelled him to declare his conviction that on almost, if not on all important points, his doctrines were supported by the phenomena of syphilis as presented in this country. Primary syphilis was defined as a specific disease communicated by a virus of which the earliest manifestation is a chancre; and secondary syphilis as a constitutional affection, which, excluding hereditary transmission, originates always from a chancre, and manifests itself by characteristic symptoms, which follow with more or less regularity a certain order of evolution. Two distinct varieties, and two only, of chancre were stated to exist: the soft or noninfecting chancre; and the indurated or infecting chancre. Either of these, although much more commonly the former, might be attacked with phagedæna, or sloughing; but these conditions are the result of external circumstances, and not of any inherent quality in the sore itself. He laid down as a principle, that, on seeing a primary sore in the early stages, we might, in five cases out of six, positively state to the patient, at the outset, a distinct

prognosis as to the occurrence of secondary symptoms, or the contrary, without risk of error; and that, in consequence, we might select the appropriate treatment at once, and pursue it with confidence. Mr. Thompson defined the external characters of the indurated or infecting chancre; contrasted them with those of the soft or noninfecting chancre; pointed out that the first was invariably attended with indurated, painless, lymphatic glands in the groin, which attested the nature of the sore, after the latter had disappeared; and stated that constitutional syphilis was certain to follow, sooner or later; the induration of the sore itself being, in fact, the first sign of the systemic infection. Next, he described the characters of the soft chancre, which was not necessarily, nor, indeed, most commonly, associated with any bubo at all; but if so, the bubo was inflammatory, and would suppurate. In this case, it was almost certain that no secondary symptoms would follow. He then considered the sores of a doubtful character, that is, those respecting which it was difficult at first to determine the nature; and showed how the two varieties might nevertheless, in most cases, be distinguished by attention to known sources of error. The treatment of primary syphilis in these two forms then succeeded. The employment of caustic, which if sufficiently powerful, and applied early, would prevent constitutional infection, was strongly recommended. The potassa cum calce, on the whole, was regarded as the best. In the soft chancre, which was met with three or four times as frequently as the indurated chancre, there could be no occasion for mercury or iodine, as it was a purely local, not a constitutional disease. Local astringents or antiseptics, and if it was slow to heal, fifteen or twenty grain doses of the potassio-tartrate of iron twice or thrice a-day formed the best treatment. Such formed the bulk of the cases so frequently reported as examples of syphilis cured without mercury; in fact, whatever the treatment of these sores, no constitutional symptoms would manifest themselves. In the well-marked indurated chancre, small doses of the iodide of mercury, such as three-quarters of a grain or one grain, guarded by about two grains of Dover's powder, appeared to suit more generally than any other form. The gums to be but very slightly touched, and the patient carefully guarded against salivation; this condition to be maintained for a considerable period. Where any intolerance of mercury by mouth was exhibited, inunction or fumigation to be substituted. Nothing, however, could be more obvious than the good effects of mercury in these truly infecting sores and early constitutional symptoms, provided its administration is kept within the limits recommended.

A tabular form, exhibiting the characters of the two varieties of chancre, by way of contrast, was presented, for the purpose of diagnosis, and showing the salient points of the subject at a glance. A copy of it follows here:—

### DIAGNOSTIC CHARACTERS OF THE TWO VARIETIES OF VENEREAL SORES.

1. THE SOFT OR NON-INFECTING CHANCRE.
2. THE INDURATED OR INFECTING CHANCRE.

#### THE SOFT CHANCRE.

##### Anatomical Characters.

Form, rounded, often irregularly so.

Edges sharp, well defined, as if cut with a punch; rather overhanging, not adhering closely to subjacent tissues. Surface, flat, but irregular, "worm eaten;" often with yellowish or greyish matter adhering.

No induration of tissues around, unless caused by caustic or other irritant; in which case the thickening is not defined in its limits, but shades off into the surrounding tissues, and has more or less the aspect of inflammatory action.

#### THE INDURATED CHANCRE.

##### Anatomical Characters.

Form, rounded.

Edges, sloping not sharply cut; hard, sometimes a little elevated, closely united with subjacent tissues. Surface, hollowed or scooped out, but smooth as if varnished; often greyish at the centre.

Induration, well defined, incompressible, like a cup of cartilage let into, or set upon, the tissues beneath, and moveable over them; no inflammatory areola. Usually makes its first appearance between the fifth and tenth day; never after the twentieth. Generally long survives ulceration.

Induration varies in degree somewhat with the situation, but when slight is nevertheless always defined.

*Pathological Tendencies.*

The secretion is contagious, purulent and plentiful, hence these chancres are rarely single; often, perhaps most commonly, multiple, one giving rise to another. It is usually slow to heal, has a tendency to spread; and is liable to take on phagedænic action.

The soft chancre appears, from the records of practice, to appear with a frequency about four times as great as the indurated chancre.

*Characteristic Gland-affection.*

In many cases (but not in the majority) the inguinal glands are affected; in which case, one gland, usually, rapidly inflames and suppurates, and an open bubo is the result. The pus, at first, is inoculable, and capable of producing a soft chancre.

*Pathological Tendencies.*

The secretion is scanty, rather serous than purulent, and is not very readily inoculated. Hence the sore is usually single, rarely multiple, and if so the sores appear simultaneously.

It is indolent, but less so perhaps than the soft chancre. Rarely takes on phagedæna.

Either sore propagated by inoculation, invariably produces its like.

*Characteristic Gland-affection.*

It is INVARIABLY followed by slight swelling and marked induration of the inguinal glands on one or both sides (the sore being on the genital organs); usually several glands are affected; they are hard, incompressible, and roll under the finger, are painless, and do not inflame or suppurate.

Except in rare instances from over exertion, in scrofulous subjects, &c., but then the pus is not specific and not inoculable.

The induration of the gland coincides in time with that of the chancre itself.

The primary sore having disappeared, or being denied, the gland-induration is an invaluable sign for purposes of diagnosis.

*Prognosis.*

The well marked soft chancre is always a local affection, and DOES NOT AFFECT THE SYSTEM; and no "specific" treatment (mercury and iodine) is required.

A highly-interesting discussion followed, in which several members took part. Many cases were related from the experience of the speakers confirmatory of the truth of Mr. Thompson's statements. In particular, Dr. Headlam Greenhow, who had had charge of a Military Hospital, and had there seen much syphilis, did not recollect ever to have seen a sore accompanied by open buboes followed by secondary symptoms. Mr. Ballard spoke to the same effect. Mr. Weedon Cooke was inclined to doubt the universality of Mr. Thompson's laws as laid down. He considered that in women soft chancres are frequently followed by secondary affections. Again, he had seen a case of indurated chancre in which no secondary symptoms followed, although no treatment had been adopted. Dr. Camps objected to the author's views, that if true they would necessitate the admission of the existence of two different forms of syphilis, which he could not allow. Mr. Cleveland cited an interesting case of indurated chancre, in which mercury was ineffectual in checking the phagedænic ulceration which followed. Mr. Robinson had found the syrup of the iodide of iron a very valuable medicine for syphilis in children. Dr. Handfield Jones, Mr. Langmore, and Dr. Panton, also participated in the discussion.

Mr. THOMPSON in reply said, he thought the day was not far distant when we should speak of chancre and chancroid to distinguish the two forms alluded to. He would only be disposed to allow the existence of *one* syphilis, although there were *two* kinds of venereal sores. In cases where soft chancres were said to be followed by secondary symptoms, he would dispute the correctness of the diagnosis; the sore had been at one period indurated. The diagnostic data afforded by the state of the glands he regarded as of great importance.

## MEDICAL NEWS.

ROYAL COLLEGE OF SURGEONS.—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 31st ult. :—viz.,

BRAINE, FRANCIS WOODHOUSE, H.E.I. Company's Service.  
DIGBY, FREDERIC, Malden, Essex.  
FISHER, JOHN, Manchester.  
FRANEY, EDWARD, Northampton.  
PIKE, THELWELL, Bucklesbury, Berkshire.  
REED, GEORGE, Portsmouth.  
SAINTER, JAMES DOW, Macclesfield.  
SMYTH, WILLIAM DICKINSON, Royal Navy.

Also, on the 5th inst. :—

ALFORD, HENRY JAMES, Taunton, Somerset.  
BELCHER, ROBERT SHIRLEY, Burton-on-Trent.  
BENNETT, CHARLES VAUGHAN SIMMONS, Haverfordwest.  
CUMSTONE, WILLIAM, Market Rasen, Lincolnshire.  
DAVIES, JOHN, Festiniog, Monmouthshire.  
HOPKINS, JOHN WALTER, Leeds.  
HORTON, J. A. BEALE, Gloucester, Sierra Leone.  
JOYCE, THOMAS, Stamford-hill.  
OCHILTREE, CHARLES WILLIAM, Seaton Sluice.  
PICKFORD, NEWBOLD, Manchester.  
RICKARDS, ALFRED, Leeds.  
SCARTH, JOHN WILLIAM, Leeds.  
SUMMERS, WILLIAM ALEXANDER, Ilminster, Somerset.

At the same meeting of the Court, Mr. William Dickson Smyth, of her Majesty's ship *Agamemnon*, passed his examination as Naval Surgeon. This gentleman had previously been admitted a member of the College, his diploma bearing date March 31.

APOTHECARIES' HALL.—Names of gentlemen who passed their examination in the science and practice of Medicine, and received certificates to Practise, April 1, 1858 :—

COCKS, BENJAMIN, Oxford-terrace, Hyde-park.  
PRITCHARD, EDWARD WILLIAM, Filey, Yorkshire.  
THORNILEY, JOSEPH, Harton Mersey, near Manchester.

## DEATHS.

BOX.—On the 4th inst., at Witney, Oxon, William Box, M.R.C.S. Eng. 1844.  
CURRIE.—On the 17th Feb., at Quilon, Malabar Coast, William F. Currie, M.D., son of the late Claude Currie, Physician-General, Madras.  
FRY.—On the 3rd inst., at Wigston Magna, Leicestershire, Augustin Fry, M.R.C.S. Eng. 1836; L.S.A. 1832.  
MARTIN.—March 30th, Francis Martin, Notting-hill, aged 39.  
M'GRIGOR.—On the 2nd inst., in Harley-street, Sir James M'Grigor, Bart., K.C.B., K.C.T.S., M.D. Edin.; late Director-General of the Army Medical Department, aged 87.  
REID.—March 28th, at Douglas, Isle of Man, Alexander Reid, Surgeon Artillery, H.E.I.C.S., aged 49.  
ROULSTON.—On the 22nd February, at Low Harrowgate, John Roulston, jun., M.D. St. And. 1851; M.R.C.S. Eng.; and L.S.A. 1851, aged 30.

## APPOINTMENTS.

Mr. S. T. Jephcott has been elected to the House-Surgconcy of the General Infirmary, Chester.

THE CITY HOSPITALS.—From the annual report just published, it appears that the following were the numbers of patients at St. Bartholomew's and St. Thomas's Hospitals last year.

	ST. BARTHOLOMEW'S.	ST. THOMAS'S.
In-patients . . .	5,839	4,507
Out-patients . . .	88,889	36,354
Died . . .	577	360
In-patients remaining . . .	579	457
Out-patients „ . . .	3,540	2,413

**CHLOROFORM IN MALINGERING.**—Dr. Hans Zoehrer has discovered, by means of the sleep produced by chloroform, the deception practised by a pretended mute, who attempted to quarter himself upon the cantonal Hospital at Munsterlingen during the winter. A full dose of chloroform betrayed his power of speech; his involuntary vociferation was of the most distinct and articulate character.

**A LAUDANUM DISTRICT.**—The *Stamford Mercury* says that "Holbeach is a great laudanum district," and, "as might be expected, the drug is sold in great quantities, not only by our druggists, but by almost every little country shop-keeper and general dealer in the neighbourhood. Judging from a single druggist's weekly return of retail sales shown to us the other day, we think we are within the mark in estimating the amount of money spent by the working-classes in this parish (though they are by no means the only consumers) in laudanum and opium, at not less than £700 or £800 a-year." Druggists find this trade to prevail excessively where teetotal societies are most flourishing.

**MEDICAL PRACTITIONERS IN VIENNA.**—According to a recent enumeration there are in Vienna 545 civil and 76 military doctors of medicine, 23 civil and 6 military magistrates of surgery, 116 barber, or lower degree of surgeons, 28 dentists, 45 apothecaries, and 1,270 midwives.

**THE ORDER OF THE MEDJIDIE.**—The Queen has been pleased to give and grant unto the undermentioned officers Her Majesty's Royal licence and permission that they may accept and wear the insignia of the several classes of the Imperial Order of the Medjidie attached to their respective names, which His Imperial Majesty the Sultan hath been pleased to confer upon them as a mark of His Majesty's approbation of their distinguished services before the enemy during the late war, and that they may enjoy all the rights and privileges thereunto belonging, viz.:—Fourth Class:—Medical Inspector of Hospitals and Fleets—Mr. David Deas, C.B. Fifth Class:—Deputy Medical Inspectors of Hospitals and Fleets—Messrs. John Rees, Charles Ritchie Kinnear, M.D. Surgeons—Messrs. John Munro, M.D., William Graham, M.D., John Stewart, Charles Deane Steele, George Mackay, M.D., Charles Robert Brien, M.D., Robert Graham, M.D., Edward Nolloth, M.D., Samuel William Webb, John Herbert Patterson, Hugh O'Hagan, M.D., John Cockin, Daniel John Duigan, M.D., William Duirs, M.D., John Traill Urquhart Bremner, John Cotton, M.D., George Mason, M.D., Ahmuty Irwin, John Wallace, Mark Hamilton, M.D., B.A., and Allan Brown, M.D. Assistant-Surgeons—Messrs. Charles George Wolfenden, Edward M'Sorley, Gilbert Lennox King, William Sylvester Roche, and William James Shone.

**IMPERIAL TROUT.**—The experiment made by order of the Emperor of the French to stock the waters at St. Cloud with trout hatched artificially has met with complete success. The trout twelve months old are 20 centimetres long, and weigh from 65 to 90 grammes. Their value, in the Paris markets, would be from 1*fr.* to 1*fr.* 25*c.* The trout 33 months old are from 48 to 50 centimetres long, and weigh from 675 to 1,170 grammes. They would sell for from 3*fr.* to 6*fr.* It is further stated that the waters at St. Cloud were never before inhabited by any species of Salmonidæ. The trout are extremely numerous, and promise to yield highly productive returns, in a commercial point of view. The principal object of the Emperor is to ascertain whether the production of fish by artificial means is more profitable than the cultivation of land, taking the same superficial area in both cases.

**LATENT LIGHT.**—Mr. Grove has given the following summary of M. Niepce's experiments on this curious subject:—"An engraving which has been for some time in the dark is exposed to sun light as to one half, the other half being covered by an opaque screen; it is then taken into a dark room, the screen removed, and the whole surface placed in close proximity to a sheet of highly sensitive photographic paper. The portion upon which the light has impinged is reproduced on the photographic paper, while no effect is produced by the portion which had been screened from light. White bodies produce the greatest effect, black little or none, and colours intermediate effects. An engraving exposed as before, then placed in the dark upon white paper, conveys the impression to the latter, which will, in its turn, impress photographic paper. Paper, in a tin case, exposed to sun-

light, then covered up by a tin cover, will, when opened in the dark, radiate from the aperture phosphorescent force, and produce a circular mark on the photographic paper, and even impress on the latter the lines of an engraving interposed between it and the photographic surface. Phosphorescent bodies produce similar effects in a greater degree, and bodies which intercept the phosphorescent effect intercept the invisible radiations. A design drawn by a fluorescent substance, such as a solution of sulphate of quinine on paper, is reproduced, the design being more strongly impressed than the residual parts of the paper.

**HORSE TAMING.**—Mr. Field, the Veterinary Surgeon, says:—"To operate with success it is necessary to be alone with the horse in a confined space, and to take care that there is nothing to divert the animal's attention. The articles required are oil of cumin, horse castor, or the warty excrescence from the horse's leg, and oil of rhodium. The horse castor is easily pulled off, and must be grated fine. It has a peculiar, rank, musty smell, the ammoniacal effluvia of which seems to be very acceptable to the horse. For oil of rhodium he has, however, a remarkable fondness. This is extracted from a wood which is brought from the Canary Islands, and is usually sold as a perfume. It is retailed at 1*d.* per drop. The *modus operandi* is:—Rub one or two drops of oil of cumin over your hands, and pass your hands over his nostril so that he inhales it. This must be continued until you get his entire attention. Then put a little of the castor (about the quantity of a good pinch of snuff) on a lump of sugar, and if the horse will not eat it from your hand put it into his mouth. Take eight drops of oil of rhodium in a little bottle or thimble, or any convenient thing, and pour it into his mouth. Usually this, with kind and gentle treatment, makes him become "your obedient servant," and he will follow you about and permit you to take any liberty with him. In extreme cases the process may have to be repeated before you acquire the desired influence over him. If you are so inclined, this operation may be repeated four or five times a-day, but, above all things, the utmost care must be taken to avoid hurting him. These directions will enable any one to make a friend of his horse, and if he be addicted to any "tricks" he can be cured.

#### REMUNERATION TO SANITARY AND MEDICAL OFFICERS.

Last week a meeting of the vestry of St. Pancras was held on the subject of the salaries of the Medical Officer of Health and the District Medical Officers, upon which there are two parties in the vestry and a great sensation throughout the parish. W. H. Wyatt, Esq., churchwarden, was in the chair, and a report was presented from a committee, recommending the discontinuance of printing the monthly report of the Medical officer of health; that the district Medical officers only be required to perform the sanitary duties they performed before the Metropolis Local Management Act came into operation; that the salary of the Medical officer of health, Dr. Hillier, be reduced from £400 to £250 per annum; that the salaries of Messrs Adams, Jefferys, and Sutherland, district Medical officers, be reduced from £180 to £130 per annum each; and that Messrs. Davis and Wildbore, also district Medical officers, have their salaries reduced from £180 to £140 each; and that Mr. Coster, sen., workhouse-Surgeon, have his salary increased from £140 to £180 per annum. Communications were read from the officer of health and district Medical officers, protesting against the proposed decrease of their salaries—Dr. Hillier, on the ground that he had given up a lucrative appointment at University College Hospital, taken up his diploma from the College of Physicians, which shut him out from general practice, and that he had taken a house on lease in the parish, on the faith of the salary of officer of health being £400 per annum, and he also urged the sanitary improvement of the parish. The district officers also strongly urged the latter point, and stated that their salaries amounted to the rate of 2*s.* 3*d.* per case, including medicines, or about 3*d.* per visit to each patient. After a most excited and angry discussion all the recommendations of the Committee were carried.

**THE ASYLUM FOR IDIOTS.**—The eleventh anniversary festival of this excellent institution was held last week, his Grace the Duke of Wellington presiding. About 200 friends and supporters of the charity sat down to dinner. The asylum has establishments for the reception of idiots at Earls-

wood, Red-hill, and at Essex-hall, Colchester, where more than 300 patients are now under its care, while upwards of 200 more are urgently craving admission. The board are ready to meet the demand made upon them by providing a hospital with 400 beds; but to effect this object they require an addition to their present resources of from £5,000 to £10,000. In proposing the toast of the evening the noble chairman made a feeling appeal to the benevolence of his auditory on behalf of the charity they had met to promote. Many other philanthropic institutions were condemned by political economists as calculated to dull the edge of industry, and to encourage improvidence; but no such objection fairly applied to the society whose cause he had the honour to plead. It could not be said that the poor idiot himself, or his perhaps more miserable parents were in any way to blame for their misfortune; and therefore they had a special and irresistible claim to the sympathy of the humane. Having called attention to the improved treatment which the class of sufferers to whom it ministered had of late years received, the noble chairman next proceeded to point out the marked success which had happily attended the endeavours of the committee to impart the elements of useful instruction to their patients, and also to qualify them to contribute towards their own support. The society, however, could not entertain all the applications for admission that were constantly being made to them, and therefore they appealed to a generous public to increase their means of doing good. Various specimens of the handiwork of the inmates of the asylum, in the shape of drawings, copy books, and several descriptions of fancy-work, were circulated round the room in the course of the evening, and much surprise was evinced by the company at the extraordinary skill and proficiency thus displayed. The subscriptions announced by the secretary as the result of the chairman's appeal amounted to about £3500.

## VITAL STATISTICS OF LONDON.

## TO CORRESPONDENTS.

Dr. CONOLLY's sixth paper on the Physiognomy of Insanity, with a Photographic illustration of Chronic Mania, will appear next week.

If M.R.C.S. is not a Union officer, and the magistrate requested his opinion, he can certainly demand a fee.

Mr. Keen's case shall appear.

Mr. Busk's letter on Pirogoff's operation shall appear next week.

Will Mr. Lissers favour us with the title of the pamphlet? It has accidentally escaped notice.

*Inquirer*.—1. Equal. The College of Physicians cannot confer degrees. 2. Yes. 3. The London degree. 4. Refer to our Student's number last year.

*A Crimean Assistant-Surgeon*.—Of some 400 Assistant-Surgeons who served in the Crimea, only 16 received the Medjidie. Some inquiry shall be made as to the supposed mistake respecting the recommendation.

*Medicus*.—We have no further information as to the African leech than that given in the extract from the work of M. De Quatrefages.

*Philanthropos*.—All must admit that it is desirable to prevent the marriage of persons affected with hereditary disease; but it would be very difficult to draw the necessary Act of Parliament.

*M.D. Edin.*—It will take a long time to educate the people up the standard which would make them despise quackery, while it would be easy to publish a register by which all could see who were quacks and who were legal practitioners.

*T.I.W.*—The case was a hard one, but we see no remedy. Mr. Brent was certainly wrong to promise a fee if he felt doubtful whether he could obtain it for our correspondent.

*Juvenis* should purchase some very elementary work on chemistry. We shall be glad of a reference to the cases in the United States showing the influence of re-vaccination as a remedy for whooping-cough. The occurrence of disease of the jaws in smokers who light their pipes with phosphorous articles is curious, if true.

*Yahoo* sends us what he calls a specimen of "oblique advertising" from the Jewish Chronicle and Hebrew Observer of March 26. It is a paragraph about the removal of a tumour from a lady 84 years of age, by Mr. Ernest Hart, and it certainly has the appearance of a very gross puff. But it is, probably, one of those attempts to evince gratitude by which grateful patients and indiscreet friends give so much annoyance to those they wish to benefit.

*Hunts*.—We never saw a more gross puff than the notice of the physiological lectures at Portsmouth. Those on the spot will know better than we can whether it has been done by consent, or is the work of some of those indiscreet friends who work, "not wisely, but too well." The insulting remarks upon the late Drs. Scott and Rolph show the very worst taste and ill-feeling; but it would be giving them too much importance to notice them further.

*ERRATUM*.—In our report, last week, of the names of those who were admitted Licentiates of the College of Physicians, John Rens, M.D., should have been John Peel, M.D.

### FOREIGN DECORATIONS.

#### TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—I have just seen in your last number that Dr. Vaughan Hughes has been offered a mark of satisfaction by the Sardinian Government if he could obtain the consent of our Government.

As you take interest in the Doctor's case, permit me to suggest that it is the duty of the Sardinian Government to apply officially to our Government to be permitted to decorate with one of their orders an officer of the English army who has done his duty in their ranks; and the application coming in this shape cannot be refused, as it is according to rule.

A MEMBER OF THE LEGION OF HONOUR.

London, April 3, 1858.

### SPINA BIFIDA.

#### TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Having seen in the reports of the Pathological Society in your last number two cases of Spina Bifida in which the tumours had ruptured before birth, they reminded me very forcibly of a case that occurred in my own practice on the 4th of November last. The labour was natural, and the child was born alive with a tumour as above mentioned, previously ruptured, ulcerated and sloughy. The child gradually got smaller, and died on the eighteenth day in convulsions. If you think the above short notice worthy of insertion it is at your service.

I am, &c.,

JOHN SLACK STEELE, L.S.A.

186, Chapel-street, Salford, March 30, 1858.  
N.B. I should have mentioned that the mother ascribed the occurrence to a fright which she had experienced (at the fourth month) on seeing a woman cut down who had hung herself.

### CHLOROXYNE.

#### TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—You will oblige by inserting these few lines in reply to your correspondent "Euripides," whose letter appeared in your journal of last week, April 3rd. The questions, though somewhat abrupt, I take for granted are couched with the gentlemanly intention of doing service to the Profession.

I reply seriatim. 1st. Who is Dr. J. Collis Browne? The list of the College of Physicians of London will answer that question most satisfactorily, indicating as it does that Dr. J. Collis Browne is a Member of that learned body by Examination. In the list of the College of Surgeons Dr. J. Collis Browne's name will also be found.

2nd. Is Dr. J. Collis Browne a Medical officer in H.M.'s service? In reply I would refer "Euripides" to the Army List from 1845 to 1856, where he will find the services of Dr. J. Collis Browne duly registered and acknowledged, and it was during his servitude in India and China as

Medical officer on the Staff of H.M.'s army that his attention was first directed to the preparation of chlorodyne.

3rd. Does chlorodyne possess the wonderful properties enumerated in Mr. Davenport's advertisement? I cannot do otherwise than direct the attention of your correspondent to the said advertisement, wherein he will find that the extraordinary properties enumerated are not enunciated by Mr. Davenport, but testimony of the Profession resulting from long-trying practical experience; the names and addresses are respectively attached to the reports; and I am quite sure that every one of the Medical gentlemen in question would willingly afford any further information. The original communications can be seen here at any time with many others equally valuable; the whole are voluntary comments for the guidance of the Profession.

4th. Are Dr. Medlock's and Dr. Horsley's analyses near the mark? As sole manufacturer and agent for chlorodyne, I beg to inform "Euripides" that they and all other analyses that have appeared are very wide of the mark, and if my assertion is doubted, prepare and compare. The physical results will be found so dissimilar as at once to obviate such doubt. Besides which the medicines suggested in these analyses have long since been tried in every form of combination, whereas chlorodyne is clearly stated by Medical men of high standing and experience to be quite dissimilar in its action to any medicine ever used in this country. I am, &c.

April 5th. J. T. DAVENPORT.  
33, Great Russell-street, Bloomsbury, London.

#### TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—A correspondent, under signature of "Euripides," in your Journal of the 3rd inst. demands:—

1st. To know who I am?  
2nd. That I "do battle for the incomparable chlorodyne."  
3rd. Depose as to the advertisement respecting its "wonderful properties enumerated by Mr. Davenport."

4th. That I give a rejoinder to Dr. Medlock's and Mr. Horsley's analyses.

1. To relieve "Euripides's" distress of mind, I direct him to a perusal of the Lists of the College of Physicians and Surgeons, London, also Hart's Army List from 1845 to 1856. I served in China, India, in transports, was at the Cape, and latterly on the Staff on home service. During my tour abroad I combated severe epidemics of Cholera Asiatica—had under my care many thousands of cases of dysentery, diarrhoea, acute, and fever, exclusive of the ordinary maladies of tropical and temperate climes; in 1854 I received a gold medal from a population in the North of England for services rendered in arresting most completely the ravages of cholera, particulars of which I have published in a pamphlet, and can be had on application by any Medical gentleman. Whether such an epitome of my antecedents may satisfy "Euripides," I leave him to state, but I am aspiring enough to believe that I have a just right to lay claim to an opinion as to what may be of important use in the prevention or arrestation of disease—and further, that I have an equal right to assert the discovery of an agent unquestionably original in the treatment of disease.

2. In 1855, Mr. Davenport undertook the manufacture of my discovery, to which I gave the name of "Chlorodyne." In his hands I have left it; if "Euripides" requires further particulars regarding this property I must refer him to the above gentleman.

3. The announcements advertised by Mr. Davenport are merely the extracts of letters and reports forwarded to him by different Medical practitioners. Nothing is stated on his own responsibility, as "Euripides" can satisfy himself on inspecting the original vouchers, equally with any other member of the Profession. Should it be desirable to obtain my own expression of its efficacy in disease, I shall be happy to do so; but as yet have refrained, conceiving anything I might say would be instantly set down to charlatanism or sheer *ex parte* bias.

4. Dr. Medlock and Mr. Horsley's analyses are as far wide of the mark as north is from south,—equally so are the misleading authorizations of others on the subject. I am, &c.

JOHN COLLIS BROWNE, M.R.C.S.L., R.C.P.L., Ex-Army Staff.  
April 7, 1858.

#### TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—In answer to your correspondent I beg to say that W. J. Collis Browne was for a while resident in Brighton, where a large brass plate fixed on the area-rails announced the hours at which he might be consulted for chest diseases, and particularly, as the very large letters indicated, for consumption. Suddenly he disappeared, and I know not where he is now. Beyond this brass plate I never heard anything to his disadvantage.

Will some other correspondent kindly tell us about W. Wallstenholme of the Tottenham General Hospital, who bears testimony in favour of Chlorodyne? I am, &c. X. Y. Z.

#### A QUERY.

#### TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—Will you kindly inform me which examination you think will rank the higher,—the Matriculation of the University of London, or the newly created one for Associate in Arts at Oxford and Cambridge?

If they rank equally, would it not be better that the University of London should call their Matriculation an "Associatehip in Arts," or at any rate give it some title which can be lettered after the name? I am, &c.

UNDERGRAD. U. L.

#### WINES FROM THE CAPE OF GOOD HOPE.

#### TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

Sir,—A correspondent of the *Times* suggests that the Chancellor of the Exchequer should equalize the wine duties, because the consumption of wines imported from the Cape of Good Hope during the past year, has increased very much, and he adds, "it cannot have arisen from an increased taste for them, but that they must have been used for adulteration only."

These assertions, if unanswered, are calculated to create no small degree of alarm, both here, and in the colony; but, if the time has arrived that the Chancellor of the Exchequer considers it necessary to tax British toll, labour, and enterprise, to the same extent as foreign, we, for one, shall not complain of a measure calculated to bring about universal free trade, although it might (for a time only) affect the interests of ourselves and others.

But we are bound to set your readers right as regards these wines

which are not used for adulteration, save by those whose easy consciences would dictate a cheaper substitute, but are now advertised in your columns by ourselves and other influential Houses, and sold upon their own merits only.

Dr. Letheby has made a most favourable analysis of our Cape wines, and states they are "pure and unadulterated, and contain the average amounts of the constituents of good wholesome wines."

The increase in the consumption of these wines can very easily be accounted for, when we tell you our sale alone for these wines during the past year was about 30,000 gallons; and we are in a condition to prove on the testimony of thousands of the aristocracy, gentry, and clergy, that the Cape wines have arrived at a degree of goodness suitable for use in this country, and decidedly superior to any of the second qualities of Portugal and Spain, many of which are not only unpalatable, but decidedly injurious. We are, &c.

W. & A. GILBEY.  
357, Oxford-st. (three doors from the Pantheon),  
London, March 30, 1858.

[We have examined eight samples of different wines from the Cape, forWARDED to us by Messrs. Gilbey, and find them equal in most respects, and in some superior, to the ordinary wines from Spain, Portugal, and Madeira. In point of acidity, strength, and sweetness, they so nearly resemble the latter wines that they might be very generally adopted in our Hospitals at a great saving of expense.—Ed.]

#### COMMUNICATIONS have been received from—

Mr. ROSCOE; Mr. HEWISON; Mr. WOOD; Mr. GRIGG; Mr. STUART; Dr. WILDASH; Mr. LINTON; Mr. SAMPSON; Mr. BENNETT; Dr. WHITE; Mr. H. HUNT; Mr. DOHERTY; Mr. BYRNE; Mr. BURNAN; Mr. MAXWELL; Dr. GREGG; A. B.; Mr. YOUNG; Mr. PAGET; Dr. CONOLLY; Dr. G. JOHNSON; Dr. CARPENTER; Dr. BEATSON; Dr. M'CRAICH, Smyrna; Dr. LAM-KESTER; Dr. WALLER LEWIS; Dr. BUCHANAN, Glasgow; Dr. GRAYLY HEWITT; Mr. LIZARS, Edinburgh; Mr. BAKER BROWN; Mr. FIELD; Mr. CUSACK, Dublin; Dr. RENTON, Edinburgh; Dr. DIAMOND; Dr. THURNAM; Mr. TOWERS; Mr. COPNEY; Mr. RIVERS; Mr. CAIRNS; Mr. REILLY; Messrs. ## APPOINTMENTS FOR THE WEEK.

### April 10. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; Westminster, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Invertebrata."  
MEDICAL SOCIETY OF LONDON, 8 p.m.

### 12. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopaedic Hospital, 3 p.m.  
NORTH LONDON MEDICAL SOCIETY, 8 p.m.

### 13. Tuesday.

Operations at Guy's, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Invertebrata."  
ROYAL MEDICAL AND CHIRURGICAL SOCIETY, 8 p.m. (Ballot, 3 past 7): Dr. Tyler Smith, "On a Case of Inversion of the Uterus;" Dr. Greenhalgh, "On a Case of Disease of the Osseous System, necessitating the Cæsarean Section."  
ROYAL INSTITUTION, 3 p.m.: J. P. Lacaita, Esq., "On the History of Italy during the Middle Ages."

### 14. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopaedic Hospital, 3 p.m.  
NORTH LONDON MEDICAL SOCIETY, Mr. Erichsen, "On Disease of the Sacro-Iliac Synchondrosis."

### 15. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Invertebrata."  
ROYAL SOCIETY, 8½ p.m.  
LINNEAN SOCIETY, 8 p.m.  
CHEMICAL SOCIETY, 8 p.m.  
HARVEIAN SOCIETY, 8 p.m.: subject for discussion, "Diphtherite."  
ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."

### 16. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.  
ROYAL INSTITUTION, 8½ p.m.: Robert Godwin Austen, Vice-President of the Geological Society, "On the Conditions which determine the Probability of Coal beneath the South-Eastern parts of England."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—  
Lithotomy; Removal of growth from clitoris. By Mr. Ferguson.

# ROYAL MEDICAL BENEVOLENT COLLEGE, (INCORPORATED BY ACT OF PARLIAMENT.)

*Patron.*—HER MOST GRACIOUS MAJESTY THE QUEEN.

*President.*—THE RIGHT HONOURABLE THE EARL MANVERS.

*Visitor.*—THE LORD BISHOP OF WINCHESTER.

*Treasurer.*—JOHN PROPERT, Esq.

The Council have much pleasure in informing the Governors of the Royal MEDICAL BENEVOLENT COLLEGE that the following Donations and Subscriptions to the College were announced by the Treasurer at the Sixth Annual Festival, held at the Freemason's Tavern on Wednesday, the 24th March, 1858,

Sir CHARLES LOCOCK, Bart., M.D., in the Chair:—

STEWARDS' DONATIONS AND SUBSCRIPTIONS.	£ s. d.	Gunston, H. Esq. East Cowes park ann. 1 1 0	£ s. d.	Orridge, B. B. Esq. 30, Bucklersbury 2nd don. 10 10 0

## ORIGINAL LECTURES.

## GULSTONIAN LECTURES FOR 1858.

AT THE

Royal College of Physicians.

By JOHN ADDINGTON SYMONDS, M.D. F.R.S.E.

Consulting Physician to the Bristol General Hospital, &amp;c.

## ON HEADACHE.

## LECT. II.

If we felt bound to make a strictly scientific classification of headaches, I think they might be distributed thus:—

1. Primary or idiopathic headache.
2. Secondary headache; which is the effect either (1.) of local changes within the cranium; or (2.) of morbid states of the blood; or (3.) of disorder of some distant organs, which is sympathetic headache.

According to this arrangement we should have to speak first of the strictly nervous headache, next of the headache dependent on structural disease of the contents of the cranium, or on inflammatory and congestive states; then of the headache of fevers, rheumatism, gout, and syphilis; and lastly, of sympathetic headache—gastric, bilious, and uterine.

But I find that the remarks on headache which I propose to make will follow in a more easy and natural sequence, if we consider the subject under the following heads:—1. Structural headache. 2. Hyperæmic. 3. Nervous or neuralgic, which will be discussed as idiopathic and sympathetic. 4. Toxæmic headache.

This distribution has been selected because while our attention will be given chiefly to the third of these divisions, it will be more convenient to have premised what little we have to say on the first two divisions.

1. The headache dependent on structural disease of the brain has nothing strictly diagnostic in its character. Such disease may exist a long time without any pain, if the growth or deposit has been slow. The addition of inflammation, so common an accompaniment or sequence, has often more to do with the production of pain than has the diseased structure itself. The worst cases are those in which the disease involves the fibrous coverings, and either puts them on the stretch, or induces inflammation in them. From the close packing of the encephalon it might have been presumed that morbid growths, if at all encroaching by their bulk on the intra-cranial space, would surely give rise to pain. But such an encroachment if rapid, though painful at first, would soon produce insensibility by pressure; but the slow extension of the disease is possibly compensated by atrophy of some part of the encephalon, or by some adjustment of the circulation. It rarely happens that the presence of organic disease needs to be inferred from pain only. There is surer evidence in the functional impairments. But I remember one remarkable case in which there was a morbid growth in a part of the encephalon where its presence could hardly have been expected to have been tolerated without the most serious functional disorders, and yet in which pain was the principal symptom. The fourth ventricle was enlarged to the size of a pigeon's egg, and it contained two hydatids. The walls of the ventricle were indurated and uneven. It was an interesting fact in this case that the subject of the disease had suffered no disorder of motion or special sensation, and no delirium. His symptomatology began and ended with pain in the head. For some time it was doubted whether he was not counterfeiting pain. In his paroxysms of anguish, he instinctively sought relief when out of bed by putting his head between his legs, and when lying down he threw his head over the side of the bed. The locality of the lesion obviously accounted for this peculiarity of posture.

Dr. Abercrombie makes a class of those cases of organic disease of the brain, in which pain is the chief symptom, the pain being often of a paroxysmal intermitting character. That it should be subject to periodical accessions and augmentations is not more surprising than is the case when pain attends organic disease, especially carcinomatous, in other parts, whether it

depends or not on varying states of the circulation of the part, or on irritation reflected from other organs, or on that tendency to intermission to which the nervous disorder in which pain consists is liable throughout the body. Still, though there are paroxysmal exacerbations, a certain degree of constancy in the pain characterises this more than any other form of headache. The patient goes to sleep with it, it haunts his dreams, and he wakes to a sense of it. Every movement of the body often aggravates it, and the agreeable excitement which will dissipate many headaches, often only adds to this. Still there are other headaches which also become worse under such circumstances. The locality of the pain in organic disease is by no means always correspondent with that of the lesion. The pain may be referred to the vertex when the lesion is in the middle lobe of the brain. But when the pain is more or less continuous, and always referred to some particular spot, there is so far reason to suspect some organic lesion, and in the progress of the case the lesion is generally indicated by the addition of some functional disorder of motion, sensation, or thought. The paroxysmal aggravation of the pain sometimes masks its real nature. Thus it has happened that the intermitting and periodic character of the pain has yielded to anti-neuralgic or anodyne remedies, and so created a belief that no serious disease existed. In one instance I remember that a patient was so notably relieved by a full anodyne, that the fears which had before been excited by his case were almost dispelled, but only to return on the succeeding day with too true a warrant in symptoms of encephalitis and coma, which ended in death. In this instance, a nodule of tuberculous matter was found embedded in the posterior lobe, surrounded by red and yellow softening.

In an excellent paper by Dr. Sieveking (*Medical Times and Gazette*, August 19, 1854), there is a careful comparison of the observations of M. Andral with those of Dr. Abercrombie as to the frequency with which cephalalgia accompanied lesions of the brain. According to the French author, this pain occurred in about half the cases; but in the experience of Dr. Abercrombie the proportion in which cephalalgia occurred was that of 3:1. A more important deduction from these observations was, that "there was no definite relation except in the instance of the cerebellum, between the site of the lesion and the locality of the pain."

2. *Hyperæmic Headache*.—The headache which belongs to inflammation of the brain or its coverings is generally denoted by the accompanying symptoms. It would be absurd for me to discuss it before this audience, except by way of keeping up the connexion of the subject. Moreover, on the principle of speaking of a well-known subject from my own experience, I would venture to say, first of all, that idiopathic inflammation of those parts has been far less frequently presented to my observation than I expected it to be when I commenced practice. Meningitis and arachnitis were very common words; but except in children, or as the result of injuries of the head in adults, I confess that I have very seldom met with cerebral inflammation in its pure form, that is, uncomplicated with tubercle, or other textural disease, or with gout or rheumatism, or as an immediate consequence of cerebral hæmorrhage, or as a sequela of scarlatina. The pain is of a most distressing nature, aggravated by every, even the slightest, form of stimulant, by impressions on the eyes and ears, by mental effort, and by motion of the body. The heat of the scalp and the fullness of the temporal arteries, and the superficial veins, give the surest evidence of the cause of the pain in these cases, to say nothing of the disturbed function of the brain, or of the character and rhythm of the pulse. The state of the superficial vessels in these cases is no less important a criterion than in those of apoplexy in relation to depletory measures, a point well insisted on by our honours. I remember some years ago in his valuable observations on that disease. But there are cases on record in which meningeal inflammation had run rapidly into suppuration, and had given no token whatever of its work, excepting dullness and heaviness running into coma.

M. Andral, in the fifth volume of his *Clinique Médicale*, makes a very elaborate analysis of cases of meningitis in reference to headache, the general result of which I find to be that there is no constancy of relation between the presence or absence, between the degree, or extent, or locality, of the pain, and the severity, or extent, or locality, of the inflammatory lesion; a result which we might have expected, *a priori*, seeing that, on the one hand, cephalalgia may have a purely independent existence, and that, on the other hand, it may

accompany or keep aloof from even greater intra-cranial disorganization than we meet with in meningitis.

Headache from congestion is one of the forms most recognised. Dr. Bright, speaking of headache in his admirable "Medical Reports," says, "That this symptom depends on various causes, and that it is connected with different conditions of the circulation in the brain, is not improbable; but in by far the majority of cases the actual condition of the vessels at the moment of the existence of headache is a state of congestion. Exhaustion from fatigue, exhaustion from the loss of blood, exhaustion from over excitement by mental exertion or bodily excesses,—all tend to produce a state of debility in the vessels of the brain which favours congestion; and these are the more ordinary circumstances under which headache occurs. The headache which follows apoplectic and epileptic attacks, that which torments the hysteric female, and that which so often attends on the dyspeptic stomach,—all probably depend on cerebral congestion, variously modified and combined, according to the causes which give rise to it, or to the peculiar state of the constitution in which it occurs." (Med. Rep. p. 222.)

Dr. Bennett, in an able essay on cephalalgia in the "Library of Medicine," remarks, "It is very probable that every species of headache, except the organic and neuralgic, depends upon a greater or less degree of congestion of the vessels of the brain." (V. ii. p. 166.)

That congestion should enter as an element into the pathology of headache might be fully expected from the mere fact, to which I have more than once alluded, of the large amount of blood sent to the brain. But, on the other hand, as it has been often remarked, more provisions have been made here than elsewhere against liabilities to any considerable variations in the quantity sent or detained. Still it is quite conceivable that an excess, of however small an amount, would tell sooner on this organ than on other parts. But there are one or two considerations which tend rather to make us doubt whether the cerebral circulation is much affected in the most common forms of headache. First, there is the long time that patients may be liable to them, without any injury ensuing. Dr. Haberdon says, "The most violent headaches will frequently harass a person for the greatest part of his life without shortening his days, or impairing his faculties, or unfitting him, when his pains are over, for any of the employments of active or contemplative life. The slightest stroke of a palsy will often be more detrimental in these respects than headaches returning often, and with great violence, from childhood to the beginning of old age. Instead of their ruining the constitution, nature seems in the contest to get the better of them."

Now, I do not think that the analogy of any other organ would allow us to infer that such impunity could attend so long a duration of those headaches if the circulation were importantly implicated. On the contrary, any long continuance of congestion is sure to tell on the texture and function of the organ. Such is the case even in the mucous membranes, with all their capacity of relief by secretion,—still more is it true of the glandular secreting organs.

Another consideration is derived from the enormous amount of the cerebral circulation. If this circulation were as frequently prone to serious disturbance as the head is to ache, it is scarcely intelligible how the organ could escape injury or its function impairment. And in the third place, the exciting causes in a large proportion of cases of headache will be found to be such as have no direct operation on the vessels of the brain. If these are involved, it is through the altered function of the organ and the disturbance of its nerves.

But although these considerations seem sufficient to make us question whether congestion takes so large and important a part in the pathology of the headache most commonly met with, as some have supposed, yet there can be no doubt that of some forms it is a marked constituent. Even where it is not an early link in the morbid chain, we must allow that as the nerves, which are the subjects of pain, are the close companions of the blood-vessels, the former, when disposed to ache, may be easily disturbed by disorders of such close and intimate associates. One of the most frequent forms under which hyperæmic headache comes before our notice is the active hyperæmia of mental or emotional excitement. It is true that under the operation of this exciting cause it might seem that the nerves are principally involved; but there are some constitutions in which the capillary circulation responds so quickly to emotional disturbance, that one can easily

understand how the vessels of the brain may be suddenly flooded. The flush of the face and neck is a pretty accurate representation of what might be the state of the vessels of the brain. In hysterical subjects such headaches are common enough under emotion. And were it not for the guards on the brain-circulation, and the difficulty of inducing a degree of cerebral hyperæmia adequate to the production of hæmorrhage, apoplexy might be as common in those subjects as are hæmorrhage from the stomach, and hæmorrhage from the respiratory surfaces. Perhaps the most powerful strain is put upon the cerebral circulation when passion and intellectual excitement are combined. We have observed the head of an orator in the full torrent of invective fury; and even had we not known what work must have been going on in a brain which was the subject at once of vehement indignation, and of rapid collection of all the stores of memory, and all the figures and metaphors that imagination could supply, as well as of the powerful effort of will by which a series of facts and arguments are marshalled and held together in such order as shall impart the force of conclusive reasoning, I say that even if one had not known by inference what transactions must have been going on within the cranium of a person so employed, and had one not known also that with all that rapid utterance, and too long delay of inspiration, and with the accelerated rate and augmented impulse of the heart's action, there must have been a combination of causes attracting blood to the cerebral capillaries, detaining it there, and retarding its exit, we might have surmised the condition from the suffused countenance, the swollen temporal veins, and the redness of the scalp; appearances that suggested the idea that the whole head was in a state of violent erection. No wonder that, under such circumstances, a brittle artery should sometimes give way, and still less wonderful that headache should be the consequence for many hours.

Strong intellectual application will induce sufficient hyperæmia to leave its traces for many hours, in those who have either a very irritable circulation—by which I mean a propensity to active hyperæmia—or who are the subjects of plethora. And when the cause has been often repeated—as in ambitious students, or in persons under the compulsion of some inevitable duty—the brain may be so surcharged with blood that headache becomes established for weeks, and the hyperæmia may end in such changes of the vesicular neurine as may reduce the intellect considerably below its former level.

The counteraction of such hyperæmia is often attempted by means of violent exercises. With a man full-blooded, full-fed, and of active digestion, it answers well. The equilibrium of the circulation is maintained, together with due action of all the eliminative organs, and the general system suffers no exhaustion by the expenditure of motor force. But when the pale, weakly student, the major part of whose life is in his brain, this organ having attracted far more than its due share of blood, when such a subject attempts to maintain his health in the same way, whether by cricket, or by football, or by rowing, he is foiled. The blood may be diverted from his hemispherical ganglia to the motor centres and the muscles, but the expenditure in the whole body is too much for his strength. He has not blood enough to maintain the waste of force at once in the thought-organ, and in the locomotive apparatus, together with all that is involved in increased pulmonary and cutaneous exhalation. In such subjects the headache of exhaustion may take the place of the headache of hyperæmia.

The hyperæmic headache, when spontaneous, is generally accompanied by a state of nerves which would alone be adequate to the production of headache. The headache of nervous women, who suffer at once from hyperæsthesia and from irregularities of circulation incident to their periodic function, is generally of this mixed kind; but it will be preferable to defer speaking of it till the nervous headache has been described.

The headache of intoxication might seem to belong to active congestion, since there cannot be a question that in the abnormal condition of the brain, produced by a certain amount of alcohol in the blood, the vessels are highly injected; but the retributive headache usually comes after the debauch, and is of a composite character. The function of the cerebral tissue so wantonly tampered with, the passive congestion of the vessels, and the disorder of the stomach and liver, are probably each and all more or less concerned in the drunkard's

headache. In its symptoms it closely resembles that which in some persons ensues on a dose of opium.

The hyperæmia, which is not of the active nature which has hitherto engaged our attention, is, perhaps, quite as frequently implicated in headache. That which is the result of diminished tonicity in the extreme arteries of the brain is the most common. It is the headache of brain-fag—not that which is caused by frequent returns of emotional excitement or extra intellectual efforts, but that which follows on long-continued, persevering over-action of the brain, whether in the enthusiastic incautious student or in the overtasked professional man. It is the want of adequate rest. The functional activity is never stopped for a length of time sufficient to allow the vessels to return to their normal condition in repose and recreation. In these cases the headache is of a dull, heavy character, and usually occupies the frontal region. In persons thus suffering we may sometimes observe a suffusion of the face and eyes of a dull crimson hue. They complain of a feeling of incapacity, and that dejection of spirits which can hardly fail to accompany such feeling. But, without any excessive intellectual strain, this form of headache may be the product of mere continued anxiety, such as may be observed in some member of a family on whom has devolved the chief responsibility of its guidance. Attention always on the alert, frequent repetition of agitating intelligence, provisions against contingencies, the vexation of disappointed plans, the difficulties incident to the domestic as well as every form of government,—the necessary employment of incapable, unwilling, or impracticable agents,—and all this in opposition to, or in evasion of, cross tempers and purposes,—such a life of the brain will sooner or later engender this form of passive hyperæmia and its attendant headache; and it is well if the headache is taken as a warning before worse results ensue.

Passive congestion from delay in the veins is seldom, I think, observed to produce headache. I think the most explicit examples of such a state are seen in the headache left by a long fit of dyspnoea, or by frequent returns of asthma, or by prolonged coughing. Sometimes, also, it is met with in persons who have accidentally fallen asleep in positions in which the head has been lower than ordinary. Something like it is also observed in men of full habit and short-breathed, who take insufficient exercise; but in such subjects there are usually other complications.

Absolute and relative plethora denote states which do not exactly correspond with those which have just passed under review. The headache of redundant blood throughout the frame is the expression by an organ which is ever ready to make demonstration of its distress, of a morbid condition which belongs to the whole system. The blood is not attracted to the organ, nor is it detained there more than in other parts, but it shares the excess which belongs to all. I know not how often this state may be met with by my brethren in the metropolis, but I must avow that such cases are of extreme rarity in the province to which I belong, and in which I have opportunities of making observations on strangers as well as on the autochthones, among whom, in former times, "if histories say true nor wrong those worthy men," might have perhaps been found some examples of excessive good living. But neither among the fixed residents nor among those who resort to our neighbourhood, have I often found such cases as are described by authors. Scarcely more than one instance remains in my memory, and it is one of a gentleman who was bled by my direction five times largely within a fortnight; and at the end of that time he was to appearance so hale and hearty that morning visitors could scarcely believe that he had been ill. There can be no question that the habits and customs of the present day are likely to correct any natural tendency to plethora. The exciting lives in business and dissipation, the wear and tear of the nervous system, the railway travelling, the sparseness and refinement and delicacy of the dietary, sufficiently distinguish the lives of public men, the gentry, and the professional men of the present day, from those of the sleepy squire, the plump pluralist, and the festive alderman, of days gone by.

But relative plethora, induced by defective action of the liver, the bowels, and the skin, is by no means uncommon, and has, undoubtedly, a causative connexion with many headaches, and is the accompaniment of others. It is found particularly among the luxurious classes, who take insufficient exercise, or chiefly of a passive kind; and though the cerebral circulation has no strain upon it from mental exertion, the

emotional excitement of a gay, if not dissipated, life will supply the morbid nervous element, which, added to the relative fulness of the brain-circulation, eventuates in headache.

Of congestive headache there is scarcely a more unexceptionable instance than that which is experienced by a person coming out of an attack of epilepsy, as I remarked in the first lecture. There may have been no complaint of pain at the outset. Whether there is pain corresponding to the hideous shriek, or whether that ominous sound belongs more to the terror which is vividly depicted for one moment on the countenance of the patient, we have no means of determining; but frequently there is an entire absence of pain immediately before the attack. The subsequent pain, then, may be fairly assigned to what has happened in the seizure. About the essential pathology of the attack, there is still plenty of room for speculation; but no one can have witnessed it, and the state which follows it, and feel any doubt that hyperæmia is present. Were there no violent injection of blood in the first instance, whether attracted by the functional condition or impelled by the visâ tergo, there would still be an adequate cause of congestion in the prolonged expiration or retarded inspiration, together with the effect of the vehement muscular contractions. The remains of the congestion are visible, not only in the suffused eyes, and in the distended veins, and in the reddened face, but sometimes also in minute ecchymoses of the skin of the cheeks and forehead. It is not wonderful that of congestion thus denoted a dull headache should be the accompaniment or consequence.

A headache engendered by active congestion is not unfrequently observed in those who suffer from violent palpitation. When this concurs with hypertrophy of the left ventricle, the cause is as manifest to the sight of a bystander as the effect is distressing to the subject. Each stroke of the heart inflicts a shock upon the brain, visibly succussing the head; yet not always with pain, thereby showing that for pain to result, the nerves must also be involved.

The headache which is connected with anæmia answers in its description for the most part, to that which we have next to speak of, or nervous headache.

3. *Nervous Headache.*—This is the headache which may afflict an individual at intervals through a long life. It belongs to all classes of society; it attacks the fine luxurious lady amid the distractions of society, and the poor half-fed, hard-worked sempstress in the solitude of her garret. But it is like other nervous affections, a product of civilization. It is said to be unknown among savages. The subjects of this disorder have an instinctive feeling that it is nervous. They can distinguish it from other kinds of headache. They know its approach, they succumb to it for the time as an irresistible evil, so much so as from frequent disappointment, to be unwilling during the attack to apply remedies, and after it is over they rebound as if nothing had happened. The duration varies—with most it continues till after a sound sleep—and in many, or in the same person occasionally, it will prevent sleep for one or two nights. It varies in degree—sometimes dull and admitting the subject of it to pursue the usual avocations of the day, though under discomfort, but oftener so acute as to make occupation an addition to the suffering. But even in this degree it does not necessarily disturb the action of the mind. The patient who has elasticity or fortitude enough to go on with the duty of the day under the anguish of toothache, will also sometimes hold up her head in company and take her share in the conversation, while racked with headache. But it oftener happens that in the severe attacks the pain is too powerful, or the endurance too weak, for the patient to stand up against it. The seat varies in different persons, and in the same person at different times according to the exciting cause. It occupies the front of the head, one temple, the crown, the occiput, or one lateral region. It belongs to all temperaments and habits of body. I have seen the strong, muscular, broad-chested, round-headed, choleric man bowed down by it; but it is far more common in persons of the nervous temperament, and in frames weak by organization or exhausted by disease and other causes. There may be a proclivity from constitutional connate, or inherited; though the predisposition would sometimes appear to be engendered by the life and habits, and by previous disease.

The original constitution most prone to it is that in which nervous susceptibility is well marked. Persons of very lively emotions and delicate sensibility, easily perturbed mind, in

easily put off their sleep, are liable to this affection, and one sees it also prevail much among those who have the æsthetical and imaginative elements highly developed. It is also the frequent accompaniment and curse of high intellectual endowments. And I think that this general statement will be found to have but few exceptions, viz. that the liability is most marked when the functional activity of the brain, whether in perception, emotion, or intellect, is disproportionate to the organic vigour of the rest of the body. I have known men of great mental power who had never felt a nervous headache, but they were full of health, possessing vigorous digestive organs and an active well-balanced circulation, together with muscles so fully developed, sufficing to make exercise a pleasure.

The condition of body, which, irrespectively of original constitution, will predispose to headache, is that which is usually described as lowered tone. In the studious class of mankind this predisposition is the result of profuse consumption of nervous force in the brain, with neglect of hygiene, and the same may be said of the condition of men who overtask their brains in professions, in diplomacy, or in commercial speculations, and who are equally regardless of the laws of health. In the luxurious classes there is the unhealthy state of body incident to late hours, hot rooms, defective exercise, the excitement of the emotions, the torment of jealousy and ambition, and worse than all, the forced efforts to be gay in spite of ennui and disappointment. The operative classes are not exempt, for their frames may be weakened by privation and hardship, while they have to live by their wits. But in this division we see the acquired constitution in question less as the result of their peculiar social position and life, than of causes common to all classes. Such is the debility ensuing on loss of blood, on deterioration of the blood, on excessive discharges, and on vicious habits and indulgences. The chlorotic girl, the mother worn out with parturition, lactation, and leucorrhœa, the father blanched with hæmorrhoids, and the son exhausted with vice, all suffer from this headache. Even the seemingly healthy youth, correct in outward conduct, is not exempt. Questions directed to elicit the secrets of his solitary life, will often prove that in such persons also, causes of terrible nervous exhaustion have been at work. Those must have been unhappy unsuccessful times for physician and patient, when that topic was ignored or evaded, or actually unknown, and when the sufferer from that cause was bled, and cupped, and blistered, under an impression that the aching giddy head was inflamed or oppressed with blood.

Some of the exciting causes show the nervous origin of this affection. They are internal and external. Of the internal, one of the most common is, disturbance of the emotions, especially when they are of a painful nature. In some individuals a prolonged fit of study, or a difficult arithmetical calculation, will bring it on. In others, too strong an impression on nerves of special sense—a dazzling light, a loud or grating noise, or a disagreeable odour; or it may be a jarring vibration, the jolt of a carriage, the shock sent to the base of the brain through the spinal column when the weight of the body falls suddenly on the heel in descending a staircase carelessly; or it may be some morbid impression on the nerves of the stomach from indigestible food, or misplaced or depraved secretions, or some analogous offence lower down in the alimentary canal. But to this subject we shall have to recur presently when speaking of sympathetic pain.

Of atmospheric conditions, comprising temperature, hygro-metric qualities, and electric states, which are known rather in their effects than in their previous composition, it is probable that several are capable of exciting an attack of nervous headache; but there are two conditions well known in their relation to the production of this pain, viz. the atmosphere which precedes and accompanies thunder, and that which precedes a fall of snow. It is also well known by the sufferers, that the pain belonging to these two excitants has each its peculiar character; that which is the effect of thunder being acute, and running along the course of certain nerves, the other more dull in its nature, and of more diffuse distribution.

I shall have to advert hereafter to the production of sympathetic headache by the irritation of particular remote nerves. But we meet with cases which show that within the cranium there may be particularly susceptible branches, which when irritated bring on a fit of pain. A lady of my acquaintance can at any time induce a fit of headache by turning the head

to the right side. In two other cases, one of a lady, the other of a most distinguished physician, the pain may be excited by lying upon the back, suggesting to the mind of the latter sufferer that congestion of the torcular Herophili might be concerned. But I incline to the belief that some of the sensory nerves accompanying particular bloodvessels may be morbidly tender, and that their compression by position induces a pain which soon radiates to other nerves. It is a state which, judging from the long period of time it may last without serious symptoms ensuing, we may presume to be unconnected with textural disease.

Of all the exciting causes, next to emotional disturbance, I have found none more common than fatigue, whether fatigue of the body, or of the mind and feelings. Too long a walk, sitting up beyond the usual hour for repose, compulsory mental attention to any subject, whether in common conversation, or in study, or in business, the exhaustion which follows the excitement of an evening party, or a journey,—all these will be occasions for the return of headache, and the more certainly if the fatigue and debility are accompanied by circumstances which produce perturbing or depressing emotions.

Muscular exercise cannot of course occur without the consumption of matter and force, not only in the muscular tissue, but also in the centres which originate and co-ordinate the movements. The extra amount of exertion incites a corresponding degree of molecular action in the encephalon; and if it be inordinate, its nerves will suffer no less than if the force were expended in intellectual operations or in emotional excitement, for the nerves in question at the same time that they are sensory are also concerned in those ultimate actions which constitute the life of the brain-matter.

In many subjects the nervous cephalalgia is called stomach, or bilious, or sick headache, because it is provoked by causes in the digestive or other organs. It is very common in females about the time of menstruation. If this function is performed with difficulty or pain, it is almost sure to bring on a headache; and when a hydraulic pathology prevailed, it was supposed that in such cases there was relative fulness of the vessels of the brain on account of the deficient catamenial discharge. But the insufficiency of this explanation might have been learnt from the uselessness of measures of local depletion as well as from the fact that in many cases the headache comes on even when there is excessive menstrual action, so that there must be something in the state of the menstrual function irrespective of the amount of discharge. In some females liable to this headache from the slightest causes, it will come on before and continue during the catamenial period, though there may have been nothing at all abnormal or unhealthy in the function as to time, or quantity, or quality; as if the mere vital movement in the ovaries gave an impulse which the irritable nerves of the head could not bear, any more than those outward events and circumstances which to persons less painfully susceptible impart only grateful and healthful excitement. Slight difficulties in gastric digestion are provoking causes in many persons, who think that by excessive care in diet they may ward off these attacks. A vain hope, for, though they may prevent disturbance from this source, it will come from some other, for the fault is in the cerebral nerves themselves, which are ready to take offence from any quarter; and the constitution uncorrected is one in which offences must arise.

Corresponding remarks may be made in reference to the intestinal functions. Constipation is blamed for the headaches, or relaxation, as the case may be. In the latter instance, it is attributed to bilious disturbance, and many and miserable may be the experiments made by the doctor, the friends, and the patient herself, for the correction of this cause of the evil; but often without satisfactory influence on that which is the essential part of the disorder. Very often artificial evils are induced, which confirm the original error of pathology. The patient has so often resorted to purgatives with a view to divert determination from the head, or to increase the flow of bile and improve its quality, or to remove irritating matters from the canal, that the bowels will not act without some artificial help. Then constipation becomes a real occasion of distress to the cerebral nerves, and when its removal brings relief to the head, the subject is confirmed in his erroneous impression that the bowels were the source of his disorder.

(To be continued.)

## ORIGINAL COMMUNICATIONS.

## THE PHYSIOGNOMY OF INSANITY.

By JOHN CONOLLY, M.D. D.C.L.

Consulting Physician to the Hanwell Asylum.

## No. 6.—CHRONIC MANIA AND MELANCHOLY.

SOME of the broader outlines of expression in the melancholic and the gay have now been brought before the readers of these papers, and illustrated by the engravings accompanying them. The painful contractions of the forehead, and deep lines in the face, and the drawn down corners of the mouth, and the fixed eye, and the heavy-lying hair, and the clasped hands, which outwardly and strongly manifest the depression and sorrowfulness of the inward mind, have been shown in various modifications. The fiercer face of the maniacal, intensely expressing destructive resolves; every muscle in lively action, and the integuments of the head seeming to communicate sentient vitality even to the hair, which is seen standing up as if sympathising with the menaces depicted in the features, have been contrasted with the smooth placidity of convalescence, in which the tension of the features has passed away, the brow has become unwrinkled, the attitude expresses repose, and the hair, no longer bristling, lies gracefully parted on the calm forehead, from which all the horrible distraction of madness has departed.

In the engraving accompanying the fourth of these papers (p. 238), the singular combination of muscular actions attending the mixed state of a patient's mind when one form of mental disorder is passing into another, as melancholia into mania, seems to be curiously expressed. The corrugation of the frontal muscles is seen to have given way to transverse wrinkles, and a partial elevation of the eyebrows, the eye having at the same time assumed an active character; as if the patient was now beginning to understand some plot, and to discern some enemies, of which the belief had obscurely oppressed her in her melancholy state; and distinct ideas of revenge were beginning to excite her. In plate V. accompanying the present number, we have a specimen of the odd characters found among the older inmates of asylums, and which, before this series of papers is concluded, must have, as they deserve, a chapter to themselves. Comical as this picture of an old woman appears at the first view, it tells a somewhat lamentable tale of long mental vexation; supervening probably among the trials of the middle or even the youthful period of life, when carelessness, unheeded or untended, a giddy mind uneducated, wild manners and irregular habits, unrestrained by any care or protection, opened a wide way to disturbance: or when perhaps frequent want, or constant discomfort, and wild disorder, or the sharper sorrows incidental even to almost homeless classes of people, unsettled the intellect altogether. The apparently careless air, the reversed bonnet, and a sort of drollery lurking in the cheeks and chin, are largely mixed with traces both of former agitation and excitement, and also with some shadows of lost hope and joy. Activity, and a certain strength of character seem depicted in the general form of the face; in the well-formed forehead, wide and high; in the broad and pronounced chin; in the development of the superciliary region of the brow, and, perhaps, even in the nose. One feels sure that once this poor woman was of a merry mind, and danced and sung, and turned her bonnet round for very mirth. Even now there is something in the position of her head and her general attitude which betokens a consciousness of being an odd and amusing object presented to the casual visitor; but the delvings of care in the forehead and in the whole face are still many and deep: the strong descending lines from the *alae nasi* to the depressed corners of the mouth, speak of alternations of depression with excitement, and make the physiognomy indicative of past attacks of mania and melancholia, both of which have left their traces there.

This odd facial expression, and the combination of various expressions, seem, indeed, to be the natural results of what was known to have been her mode of life. She was by occupation a washerwoman, and, no doubt, for a time active and hard-working. Advancing to middle age, and beginning to

feel the exhaustion incidental to daily labour, she began to seek the resource of temporary stimulants, and, soothed and stupefied with gin, became less and less careful as to food, or to food of a good description: for gin seems to silence hunger as it silences conscience. She became occasionally violent, and at length unmanageable except in an asylum; to which she was taken seventeen years ago. The regular life led there, the good food, the general regulations of the plate, and occasional Medical treatment, had their usual good effects. In the laundries of our large asylums near London such cases abound. You see a number of active women, busy at the washing-tub, or dexterous in mangle and folding, but whose air and manner, and somewhat fiery countenance, show that they are not always so composed; and, indeed, the nerves of visitors are generally more likely to be shaken in the crowd of these useful but eccentric laundresses than elsewhere; for it is the custom of many of them, on some sudden impulse, to break off from work at once, and exhibit much violence of voice and gesture. Formerly the nurses, as excited as the patients, used to overpower them and carry them off by main force to the refractory ward, in their progress to which their shouts and remonstrances diffused alarm over nearly the whole building. They are now understood much better. The peculiar form and duration of such outbreaks in these hard-working women are quite familiar to the head-laundress and her assistants; and by observing a rule of very wide application and utility in managing asylums,—the rule of letting them alone,—the most obstreperous among them, after satisfying her mind by the unrestrained expression of her uncontrollable anger, will resume all the activity of the washerwoman, and perhaps give no more trouble for weeks to come.

Such appears to have been the character of the old lady in the reversed bonnet. But the maniacal attack being the first she had experienced, and occurring when at a curable age—a little more than forty—the asylum-influences had a happy effect upon her, and in about eleven months she was discharged cured. But there are patients who seem, however apparently well, still to require this external influence to keep their minds rational; and this poor woman appears to have been one of them; for although it was said that she did not relapse into intemperate habits as to drinking, she was not found to be an endurable neighbour when at large, and was very soon taken back to the asylum. She had acquired the habit of taking large quantities of snuff, a fondness for which appeared to have superseded the fondness for gin; and to obtain snuff she was capable of any cunning, or sometimes of any violence. Even the habit of snuff-taking, the most difficult, it is said, of all small indulgences to be wholly abandoned, she was persuaded to give up, with very great advantage as regarded mental tranquillity and general behaviour. Now and then fits of violence still occur; but her usual state is that of an odd, cunning, mischievous patient, delighting in eccentricity of dress.

If favourably situated, patients of this description commonly become calmer with advancing years. Occasional tricks, and fits of passion, now and then occur; but they give little trouble. Age is already telling on this subject of chronic mania. The countenance, although not wholly sad, has nothing comfortable in it. The aged head, inclined to one side; the drooping of the right shoulder; the listless and pendulous arms; seem to indicate the weariness of one long driven about by various disturbing passions, and whose grey hairs will soon lie in the grave in which, at length, rest comes to the troubled, and peace to the turbulent.

The comfort of all living beings has been chiefly secured to them by the beneficial adaptation of their structure, their sensations, and their faculties, to the surrounding world; so that infinite variety may be met without great suffering. Modifications or changes in the nervous system, often mysterious and inexplicable, but neutralising this adaptation for longer or shorter periods, produce, in lighter forms, the unequal spirits and variable afflictions of the valetudinarian, whom every change of wind affects; or of the hypochondriac, who thinks many incurable maladies co-exist in his frame. In their severer forms, involving the nerves of sensation, or the brain itself, man's relation to all the circumstances around him becomes painfully changed. He sees objects which have no real existence, he hears imaginary sounds; his taste, his touch, his sense of smell, all become unfaithful teachers or tormentors; or all the circumstances in which it is the proper business of his life to act are discoloured or distorted; and

all his natural affections confounded; so that he no longer justly estimates his position and relations in life; and at one time nourishes every form of vain excitement; while at another, surrounding circumstances being still unaltered, thinks all nature invested with gloom, and himself ruined and lost, and condemned to everlasting woe.

Inequality of spirits, passing fancies, caprices, and even temporary moodiness of mind, usually present themselves in forms rather amusing than afflicting. But our old and venerated preceptor of physic in Edinburgh well reminded us, in his admirable *Conspectus*, of the relationship between these and graver affections of the mind. "*Omnis præter solitum hilaritas ad insaniam vergit; et æstus et meticulosus animus ad melancholiam appropinquat.*" So that a careful attention to preserve an equal mind can scarcely be too strongly enforced. In the extremes of these variable conditions consists a large portion of the unspeakable affliction which justifies the observation of our great English moralist, that "of the uncertainties of our present state, the most dreadful and alarming is the uncertain continuance of reason." Those who merely pay a cursory visit to an asylum may scarcely think so strong an expression justifiable; for many of the patients are tranquil, many occupied, and not a few seem so cheerful as to confirm the popular notion that there may be a happiness in being mad. But there are few among the insane, especially of the more educated classes, who have not an inward and painful sense of their position, and few or none who always forget that, for them, all the sweet uses of this world are lost. The aspect of those afflicted with melancholia, their countenances, their unregarded dress, their sorrowful attitude, and the deep dejection conveyed by their terrible words, sufficiently declare the dreadful truth that their anguish is more than they can bear.

Of all the trials apparently incidental to human life, the proneness to dejection of mind as age advances may, I think, be reckoned amongst the greatest. Few even of those who escape this penalty of senility owe their immunity so much to the strength as to the growing weakness of their minds. In earlier years, great intellects may be struck down for a time, and recover; the religious melancholic recovers hope; imaginary fears, built on scruples of a conscience diseased, may be demolished; spectres of ruin may be exorcised. Many such cases, depending on bodily ailment, are superable by medical treatment. After sixty years of age, we see too often the brain of vigorous men, to whom morbid fancies have been before unknown, becoming incapable of rallying under sorrow; losing energy, and falling into total inaction. The external form may remain; the grave and wise look, the sensible and intelligent face, the grand head; but the patient gazes upon you as upon a picture, and speaks not a word. Some who for many long years were active in business, and easily pleased with the common relaxations of social life, lose at once all their activity and all their vivacity; become unfit for business, and incapable of pleasure; are no longer useful, but can derive no enjoyment from leisure. Each morning, thenceforth, dawns upon them without a plan for the day; no pleasant sense of profitable labour to be done; no prospective participation of social meetings or family happiness. In these cases the energy of the brain is dead; and such patients are not in general much afflicted by their own position. Those who suffer the most are generally such as are more highly cultivated, whose aspirations have been higher, perhaps whose occupations have been nobler or more useful, but who have a morbid and regretful sense of all the hopes and joys which age steals away; want the power of bearing up against the ills of old; and wholly forget that age is as natural a part of life as youth, and that it is as natural to die as to be born.

This kind of creeping sorrow is the more painful, because the victim himself suspects it must be sinful. It is also felt to be degrading to him, because it is against his reason; and yet he cannot dissipate it by reasoning. It is afflicting, because it is still recognised by the declining mind as inconsistent with the duty of the creature to the Creator, and implies an ungrateful forgetfulness of the thousand blessings scattered over the early path of life, and of some, now that the winter is approaching, which still, like autumnal flowers, adorn the declining time.

Thus, the ablest minds of antiquity, and the ratiocinations of some of the most pious men of modern times, have been applied to prove that age is not an evil, and applied in vain. The natural tendency of the mind in age is still to melan-

choly, as the tree bows to the earth before its fall. In the strongest men, its accompaniments are labour and sorrow. If the man of thirty could foresee how many of his friends would be removed from the world before he reached his grand climacteric, his heart would sink within him. The illusions which make up the promises of early life, and impel him to fill the circle marked for him by heaven, would vanish at once. The aspirations which spur him to useful industry would die. In a world of such quick successions, all such things would seem futile and foolish. He would see before him only growing infirmities and solitude; and would have but a distressing foreknowledge that every additional year would bring additional weight upon his limbs and upon his heart; and would associate every street of familiar towns, and every lovely scene from towns remote, with mournful mutations, and recollections full of never to be removed sorrow.

It is not satisfactory to conclude that such reflections must predominate in the closing years of life. Medicine may be powerless, and philosophy. The tone recently adopted by the chaplains of some asylums prevents much hope of success from being based on their exertions. Their ministry might be healing and valuable; but these well meaning persons must be differently educated, and their knowledge of man and nature much enlarged before they can be safely introduced into private establishments for the insane of the educated classes, an arrangement towards which there are recent manifestations of a leaning well calculated to excite apprehension. The task of a chaplain ministering to those unsound in mind is always delicate and difficult. Conventional modes of approaching the important subjects they wish to introduce are wholly out of place, and proud denunciations both foolish and abominable. In no undertaking do times and seasons more require attention. One ill-chosen text, one ill-selected illustration, one rash word may turn aside a scornful maniac, or extinguish the last spark of hope in a melancholic patient. Paternal kindness, the avoidance of pomp, and the preservation of a kind of family and affectionate character in all the services, seem generally to be the most efficacious in calming and winning the troubled hearts of those who are not insensible to religious truth, and yet not in their perfect mind.

Lastly, men whose lives have been passed usefully, and benevolently, and without more than the sum of frailty inseparable from an imperfect being, should not be without consolation, nor even, whilst life lasts, sink into inaction. The past may be unsatisfactory, and the *memoria bene actæ vite, multorumque benefactorum recordatio*, of small efficacy; but every man, old as well as young, if not insane, may yet pursue truth, and do good. If he could also govern himself in all things, his life, the longest life, would be too happy, and "earth payed like heaven." There are also, it is our trust, new forms of life beyond this life; and many high consolatory truths which a reasonable man should not forget, although it would be presumption to dwell upon them in this place.

### THREE CASES OF VESICO-VAGINAL FISTULA.

By J. BAKER BROWN, F.R.C.S.,  
Surgeon-Accoucheur to St. Mary's Hospital.

#### VESICO-VAGINAL FISTULA—OPERATION—CURE.

Mrs. K., aged 22. I was called to see this lady by Mr. Kiach, who gave the following history:—About six weeks ago she was confined of her first child. The labour was very long and tedious, and the head remained in the pelvis for many hours without making any progress whatever, so at last the forceps were applied, and after a good deal of difficulty the child was abstracted. She progressed without any unfavourable symptom till the sixth day, when she perceived that her urine was constantly escaping, without her being in any way conscious of it, and that it did so in all postures equally. This continued without alteration, although her general health rapidly improved, and she was able to sit up in perfect comfort in every other respect at the usual period.

Upon examination it was discovered that there was an opening, which would admit a middle-sized bougie, situated just at the junction of the bladder with the urethra.

The edges had not become at all callous, but were soft and yielding. Every drop of the urine escaped through this fistula.

February 2nd, 1858.—I proceeded to operate, assisted by Dr. Priestly and Messrs. Kisch, Nunn, and Philip Harper. The patient, being placed in the usual lithotomy position, and a full-sized wood bougie being introduced into the bladder through the urethra, so as to raise the fistulous opening well into sight, and to give a little support while the edges were being pared, I proceeded to split up the coats of the bladder, first dissecting a narrow strip of mucous membrane from the edges of the fistulous opening, and turning the so-dissected edges, without removing them, back into the fistula, thus obtaining a raw surface. Having done this I inserted three double silk sutures at regular intervals through the split surfaces, and then tied these over two pieces of fine elastic bougie about an inch in length, and by this means the two raw surfaces were brought into close, equal, and exact apposition, and by careful manipulation no portion of mucous membrane was allowed to get between. The parts were then covered with dry lint, and the usual bent catheter, with an india-rubber bag attached, introduced, and left in the bladder.

Two grains of opium were given as soon as the effects of chloroform had a little subsided. The patient continued nursing her baby.

On February 8th I found that the sutures had cut themselves out; when I syringed the vagina, which I did every day, they came away in the basin. There had been not the slightest escape of urine up to this day. She was therefore allowed to leave off the catheter. In four days, viz., the 12th, she was allowed to pass the urine herself every three hours. In two days she found she could go five, six, or eight hours at night, and then pass it naturally, none escaping involuntarily, but on beginning to dress or suckle the child, some escaped from the urethra, which seemed to come away from want of controlling power. On carefully watching the parts where the fistula was, and requesting her to cough, I could see a drop or two percolate through the united surfaces, just like the escape of perspiration from the pores of the skin. I applied caustic to this part, as the mucous membrane of the vagina had not yet covered over the parts operated on.

Thursday, 18th.—The nurse saw a small escape from the vagina; but from that time till the 22nd there had been no escape, except occasionally in the day a drop from the urethra, although the patient walked about the room.

March 2nd.—There has been no escape, and, on a most careful examination I found there was no sign of an opening; and, indeed, the vaginal mucous membrane had completely covered over the parts united, so as to leave no trace of the fistula. She walks about up and down stairs, and the urethra has perfectly recovered its normal action.

*Remarks.*—This is a case of great interest, and offers some practical points for observation.

1. It will be noticed that the first operation succeeded; a rare occurrence in this most serious lesion.

2. The sutures were not removed, but were allowed to cut themselves out, after the plan recommended by Mr. Hayward, of Boston, United States.

3. The operation was performed only a few weeks after the lesion was discovered, and before the edges were callous, or much inverted—a point, I believe, of the greatest importance; and I laid great stress on it when first consulted, and would not allow even the nursing of the infant to delay the operation. The wretched condition of any patient suffering from this lesion is at all times one of the most distressing and loathsome kind; and in this case, where the young wife was of a lively temperament, clever, cheerful, and fond of society, it was peculiarly trying and sad, and threatened to break even her high and buoyant spirit.

**VESICO-VAGINAL FISTULA—THREE YEARS' DURATION—NINE OPERATIONS—CURE.**

Elizabeth Tranter, at 36, from Cirencester, was admitted into Boynton ward in February 1855, and gave the following history:—In November 1854, she was taken in labour with her first child, and after forty-eight hours instruments were used, and she was delivered of a still-born child. She went on pretty well until about the ninth day, when a good deal of pain in micturition came on, and she continued in great pain throughout the next three days, when suddenly, on the twelfth

day, she felt something give way, and her urine escaped through the opening and she became quite easy. From that period all her urine escaped in this way. On examination, per vaginam, I found a large opening extending transversely completely across the centre of the bladder, and so wide as to admit easily two fingers. The destruction of tissue was so great, and the fistula so gaping as to render any present attempt at closing it quite out of the question. I, therefore, determined to adopt a plan recommended by Jobert de Lamballe, viz. to dissect the neck of the bladder from the pubes and its descending ramus, thus allowing the anterior half of the bladder to go backwards, and thus relax the fistula. Great success followed this operation, and in April 1855 I pared the edges and brought them together by Sim's mode of treatment. But little success followed the operation, and she was allowed to return into the country for the improvement of her general health, and in April 1856 she was delivered of a living child.

On December 19, 1856, she was again admitted into Boynton ward, and I performed Bozeman's operation with the result of closing eight-tenths of the opening.

In five weeks I again operated, with but little success.

In six weeks more I operated, and again with little success, as great sickness always followed the use of chloroform.

So, in three days I again operated without chloroform, and the result was the closing of a third of the fistula. After this she returned into the country.

Dec. 7, 1857.—She was again admitted, and I performed Bozeman's operation; with the result of a further reduction in size of the fistulous opening. She then went again into the country.

On February 15, 1858, she was admitted into the Boynton ward, and stated that since the last operation she had been able to retain the urine during the night, and some even during the day, whilst she was sitting quite still.

17th.—I carefully denuded the edges of the fistula, and slit up the coats of the bladder all round, and then brought the raw surfaces together by silk sutures and quills.

20th.—She felt the sutures give way, and the urine make its escape.

24th.—She was taken into the operating theatre for the ninth time, and without chloroform I revived the edges, and, passing three silver wire sutures, closed them down with Bozeman's button.

25th.—No escape.

26th.—No escape. Some headache and slight pain in the vagina.

27th.—Nurse thinks a little urine escaped last night and again this morning, but I examined and found that it evidently came from the urethra. The sphincter having relaxed from the presence of the catheter.

March 4.—Bowels were well moved. No escape of urine. Catheter removed.

6th.—The button was removed, and the whole opening was found beautifully closed and quite firm.

10th.—On most careful examination, the fistula was found quite closed, and she can pass and retain her urine as well as she ever could before the lesion, and she is consequently in good spirits and very grateful.

*Remarks.*—This case is so interesting as to require but little comment. It will be observed that she was three years under treatment, and I performed nine operations upon her from first to last. The result is a good encouragement to persevere in these most difficult lesions.

**VESICO-VAGINAL FISTULA—FOUR AND A QUARTER YEARS' DURATION—OPERATION—CURE.**

Mrs. N., Rotherhithe, aged 28, consulted me in March 1858, and gave me the following history:—“Four years and a-quarter since was in labour of her first child from Wednesday evening until Sunday morning, when Mr. Peete was called in, and delivered her with forceps of a still-born child. Directly after she was made comfortable in bed she found the urine escape through the vagina, and from that time it has always escaped except when lying on her back. Three months after the accident she went into Guy's Hospital, and was there for nine weeks. She then went to a hospital for diseases of women, and was there recommended a large blister to be put on her back so as to make a sore; but, as her husband thought that could not heal the hole in her bladder, she

did not apply it, and left off attending the Hospital. Mr. Peete had repeatedly advised her to see me."

On examination, I found a small fistulous opening at the fundus of the bladder, close up to the os uteri, which was also much torn. The fistulous opening was about the size of an ordinary pocket-case director.

On March 3 I proceeded to operate, assisted by Messrs. Hume, Peete, Philip Harper, and my son, Arthur Brown. Placing her on her knees and face, without chloroform, I carefully pared the edges, removing as little mucous membrane as possible, and then performed Bozeman's operation; but, instead of bringing the edges together transversely as usual, I brought them together horizontally. The bent catheter, with bag attached, was then introduced, and opium given.

4th.—No urine has escaped.

6th.—All well, except sickness caused by the opium, which is therefore discontinued.

7th.—No escape. Bowels opened by an enema.

9th.—Still sick. A dose of calomel, followed by a Seidlitz powder.

11th.—Quite well. No sickness and no escape.

13th.—I removed the button to-day, and found the opening perfectly and entirely healed.

This case is quite a contrast to the one I have just related, and is another of the rare cases in which one operation succeeds. It is altogether most satisfactory and pleasing.

17, Connaught-square, Hyde Park. March, 1858.

#### CASE OF

### CANCER OF THE THYROID GLAND,

WITH A SMALL BONY TUMOUR.

(Under the care of GEORGE WELFORD, Esq.)

[Reported by JAS. BARROW, Esq.]

F. S., aged 54, was seen for the first time on Sept. 21, 1857. He stated that he began to observe a swelling on the left side of his neck some short time before, perhaps about three months or more, and which steadily and somewhat rapidly extended across the throat to the right side. It gave no pain for a good while; but at last the right side began to increase very perceptibly, and then he commenced to complain of pain extending from the point of the right shoulder to the back of his head. This pain was not persistent at first, but gradually, as the swelling increased, it became so, there being no pain, however, in the tumour itself. At the first visit the swelling was observed to be very much larger on the right than on the left side, and extended from the mastoid process down to the clavicle, and across the front of the neck, pushing the pomum Adami quite to the left side. Immediately below the ear, on the right side, several of the cervical glands were very much enlarged. The integuments over the whole surface of the tumour were much stretched, and very tense, giving to the touch the sensation of deep-seated fluctuation.

About a fortnight after the first visit, matters getting worse, a consultation was held; and, though no doubt could be entertained that the tumour was a malignant growth, it was considered advisable to introduce an exploring needle into the most fluctuating point, but nothing except a drop of dark grumous-like blood escaped. Refusing everything solid, he took for the first few days a little beef-tea, but afterwards nothing but stimulants, in the shape of brandy, etc. For the last three weeks of his life he expectorated a quantity of bloody mucus, his voice assumed a peculiar cracked, whispering sound, the swelling rapidly got larger, the patient weaker, and on the 27th of December, five weeks after the first visit, he died.

The patient had been a strong, powerful man, was in the best of health previously, showing no disposition to disease of any kind; by trade a gardener, consequently had much out of door exercise. Unfortunately for himself, he had for the last two years become a tippler, did not take proper nourishment, became depending in mind in consequence of business, his constitution became impaired, and at last disease manifested itself in the shape of schirrus affection of the thyroid gland.

The following notes of the post-mortem appearances were taken, as well as the examination made, by F. Paull, Esq.

*Post-mortem.*—The integument, although much stretched and very tight, was found on examination to be quite healthy. On reflecting it, the subcutaneous tissues presented a normal appearance, but the deeper seated tissues were found more or less altered in position and structure, especially those of the right side. The sterno-mastoid muscle here lay upon the surface of the tumour, being much stretched and atrophied; the muscle on the left side, with the exception of being somewhat displaced, was natural. The whole of the deep fascia in the neighbourhood of the tumour was adherent to it, and exerted a firm resistance to its encroachments on other parts. The muscles on each side of the middle line of the neck were much displaced, and on the right side so much attenuated as scarcely to be visible. All the above structures, which could be removed, having been dissected off, the surface of the tumour was exposed, and presented the following appearances:—Form, irregular, consisting of two lateral masses, and a middle connecting portion, corresponding to the lobes and isthmus of the thyroid gland. The right lateral portion, which extended from the sternal end of the clavicle to the angle of the jaw, was of a reddish-brown colour, and soft pultaceous consistence; the isthmus was much paler in colour, and of a firmer substance; the left lateral mass presented the same appearance, and was of the same consistence as that of the right, with the exception of not being quite so soft.

On removing the tumour, and examining the posterior surface, the larynx and œsophagus were seen very much displaced to the left side, the former quite immovable, and embedded in the substance of the tumour, and the latter adherent to its surface. On slitting up the œsophagus, the mucous membrane, although intact, presented a congested condition throughout, and for the space of about an inch was in quite an ecchymosed condition. The interior of the larynx was healthy.

On cutting into the tumour, the lateral portions were found to consist of soft pultaceous masses of a dirty red and fawn colour, having the appearance of the contents of an aneurism after they have been washed, intersected by portions of a pale colour and firm consistence, and some clots of blood. In the left lateral mass a bony cyst, of the size of a large marble, and containing some dirty brown-looking fluid, was found adherent to the back and left side of the larynx; and immediately below this, a hard scirrhus tumour, about the size of a small apple, evidently the primary seat of the disease, and from which the soft tumour had proceeded. The right carotid artery, although embedded in the tumour, presented a perfectly healthy appearance.

#### THE LONDON

### PRACTICE OF MEDICINE AND SURGERY.

#### THE DREADNOUGHT HOSPITAL SHIP.

#### UNUSUALLY EXTENSIVE COAGULATION OF THE BLOOD IN THE VEINS.

(Communicated by F. M. COBNER, Esq.)

H.M., aged 63, an anæmic and feeble man, with enlarged radials and arcus senilis, was admitted into the Dreadnought, February 15, for chronic dysentery. On March 8, he was attacked with acute pleurisy of the right side attended by effusion. On the morning of the 11th of March he was noticed to have a wild vacant appearance about the eyes, and was slow in answering questions; in the afternoon he became delirious, and about 8 p.m. was convulsed, squinted, and breathed stertorously. He remained in this state, breathing laboriously ("dying hard," as the nurse termed it), until 11 p.m., when he died. At the autopsy, sixteen hours after death, there was found in the head much subarachnoid effusion, a sodden condition of the brain, and the lateral ventricles distended with clear serum. In the chest there was an increased quantity of pericardial fluid; and the right cavities of the heart, which were relaxed, were filled by firm fibrinous coagula. On examining the veins, coagula were found filling the superior cava, the venæ innominatæ, the subclavians and internal-jugulars, a perfect cast of these vessels being removed without breakage. On laying open the lateral and oc-

capital sinuses and the torcular Herophili similar casts were discovered, though mixed with clots of blood. From the pulmonary artery and its branches to a second division was removed the same unmixed fibrinous clot, and in the inferior cava was a smaller clot, and more sanguineous coagula. The left auricle and ventricle were contracted and contained small fibrinous coagula. In the right pleural cavity was about a pint of turbid serum and much fibrin. The heart and lungs were healthy, the latter loaded with serum. In the abdomen was the remains of capsular inflammation of the liver and spleen, and a softened condition of the mucous membrane of the large intestines. The kidneys were far advanced in granular degeneration.

The erroneous opinions formerly prevalent respecting the import of fibrinous coagula in the heart are now almost universally abandoned. It is generally recognised that a chief cause of unusually extensive or firm coagulation is a prolonged act of dying. Feebleness of system, and the presence of certain poisons in the blood, are also efficient predisponents in the same direction. Thus these coagula are not, as once held, the cause of death ("polypi of the heart"), though it is very possible that in certain instances their presence may prevent the rallying of patients in *extremis*, who might otherwise have been brought through. The above case is of interest, as exemplifying the influence of the conditions to which we have alluded. It is scarcely probable that the serous apoplexy was a mechanical result of the venous plugging, since its symptoms set in before the act of death commenced. It, and also the pleurisy, were no doubt consequences of the disease of the kidneys.

## THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

### STATISTICAL REPORT OF THE PRINCIPAL OPERATIONS PERFORMED DURING THE YEAR 1857.

(Continued from p. 874.)

THE subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

#### AMPUTATIONS—concluded.

*Of the foot.*—Case 130.—The Dundee Royal: Dr. Crockatt.—A girl, aged about 20. Amputation at the ankle-joint, on account of diseased tarsus of two years' duration. Recovery. Case 131.—The Sheffield: Mr. Barber.—A man, aged 26. Amputation at the ankle-joint for old standing strumous disease. The wound healed very slowly. A small portion of bone exfoliated. Recovered. Case 132.—The Bradford: Mr. Poppleton.—A woman, aged 24, the subject of strumous disease of the metatarsal joints. Amputation through the metatarsus. Recovery. Case 133.—The Bristol General: Mr. Godfrey.—A woman, aged 23. Chopart's amputation for carious disease of the tarsus. Recovery. Case 134.—The Sheffield: Mr. Barber.—A man, aged 24. Amputation through the metatarsus on account of chronic disease of the bones. Recovery. Case 135.—The Liverpool Royal: Mr. Bickersteth.—A delicate girl, aged 18. Amputation at the ankle-joint on account of strumous disease of the tarsus. Recovery. Case 136.—The Liverpool Royal: Mr. Bickersteth.—A strumous boy, aged 13. Amputation at the ankle for disease of the joint. Recovery. Case 137.—The Cheltenham: Mr. Eves.—A lad, aged 19. Primary amputation through the metatarsus on account of crushed foot. Recovery. Case 138.—The Dundee: Dr. Crockatt.—A man, aged 22, the subject of diseased metatarsus. Chopart's amputation. Recovery with a good stump. Case 139.—The Glasgow.—A girl, aged 9.

*Primary amputation at ankle-joint on account of crushed foot. Recovery.* Case 140.—The Glasgow.—A woman, aged 21. Amputation at ankle-joint on account of strumous disease of the tarsus of fifteen years' duration. Recovery. Case 141.—The Glasgow.—A lad, aged 18. Primary amputation at the ankle-joint on account of crushed foot. The bone protruded, the flaps having sloughed. Healed by granulation. Recovery. Case 142.—The Leicester: Mr. Paget.—A man, aged 28. A primary Chopart's amputation was performed. The man made a tedious recovery, but the stump was ultimately a good one. Case 143.—The Dundee: Dr. Crockatt.—A man, aged 40, in very delicate health. Amputation at the ankle-joint on account of disease of the tarsus following an injury. Abscesses formed, and he sank under the hæmorrhagic exhaustion induced.

*Of the upper extremity.*—Case 144.—The Cheltenham: Dr. Wright.—A boy, aged 4, had his elbow and arm crushed in a machinery accident. Primary amputation. Recovery. Case 145.—The Liverpool Royal: Mr. Bickersteth.—A healthy man, aged 57. Amputation through the forearm six months after an attack of phlegmonous erysipelas which had rendered the hand useless. Recovery. Case 146.—The Bristol General: Mr. Coe.—A man, aged 27. Amputation through the arm on account of intractable ulceration (malignant?) in the cicatrix of a burn. Recovery. Case 147.—The Dundee Royal: Dr. Williams.—A lad, aged 12. Primary amputation through the forearm on account of crushed hand. Recovered. Case 148.—The Dundee Royal: Dr. Crockatt.—A lad, aged 14. Primary amputation through the arm, on account of crushed elbow. Recovery. Case 149.—The Gloucester: Mr. Wilton.—A healthy man, aged 60. Amputation through the forearm, on account of malignant ulceration on the back of the hand. Recovered. Case 150.—The Queen's, Birmingham: Mr. Sands Cox.—A strumous boy, aged 6, in very feeble health, the subject of severe chronic disease of the elbow-joint. Amputation. Recovery. Case 151.—The Staffordshire General: Dr. Masfen.—A man, aged 53, in bad health, the subject of diseased elbow-joint. Amputation. Recovery. Case 152.—The Staffordshire General: Dr. Masfen.—A man, aged 60, in good health. Amputation, on account of disorganized carpus. Recovery. Case 153.—Addenbrooke's, Cambridge: Mr. Hammond.—A healthy man, aged 38, the subject of diseased wrist-joint. Amputation. Recovery. Case 154.—The York: Mr. Husband.—A healthy man, aged 23. Primary amputation through forearm, on account of crushed hand. Recovery. Case 155.—The York: Mr. Hay.—A lad, aged 14, admitted for a gun-shot wound of the hand. Primary amputation. Recovery. Case 156.—The Leicester: Mr. Macaulay.—A healthy lad, aged 11. Primary amputation, on account of injury by a straw-cutting machine. Recovery. Case 157.—The North Stafford: Mr. Garner.—A boy, aged 14. Primary amputation for crushed hand. Recovery. Case 158.—The Leicester: Mr. Benfield.—A boy, aged 14. Primary amputation at the wrist-joint, for crushed hand. Recovery. Case 159.—The North Stafford: Mr. Garner.—A boy, aged 13, in good health. Primary amputation through the forearm. Recovery. Case 160.—The Bradford: Mr. Meade.—A boy, aged 13, whose elbow-joint had been excised nearly a year before. The parts had healed for a time, but a relapse took place, and necrosis of a considerable portion of bone rendered amputation needful. Recovered. Case 161.—The Leicester: Mr. Macaulay.—A healthy boy, aged 11. Primary amputation, through forearm. Recovery. Case 162.—The Leicester: Mr. Macaulay.—A strumous lad, aged 10, was admitted in consequence of a severe crush and bruise of the hand. When the sloughs separated the wrist-joint was opened, and the ulna and radius exposed. Secondary amputation. Recovery. Case 163.—The Derby: Mr. Fearn.—A man, aged 45, admitted, having had his left hand and ankle crushed by the fall of a boiler. Primary amputation through forearm, and secondary, (seventeenth day) through the leg. Recovery. Case 164.—The Leicester: Mr. Macaulay.—A healthy man, aged 20. Amputation through the arm, on account of a very large tumour, of six months' duration, and involving the lower part of the humerus. Recovery. Case 165.—The North Stafford: Mr. Garner.—A man, aged 45. Primary amputation, on account of crushed elbow. Recovery. Case 166.—The Leeds: Mr. Teale.—An unhealthy man, aged 50. Amputation for disease of the elbow joint, of two years' standing. Recovery. Case 167.—The Staffordshire General: Dr. Masfen.—A healthy

man, aged 60. Primary amputation through the forearm. Recovery. *Case 168.*—The Glasgow.—A lad, aged 15.—Primary amputation at the shoulder-joint. Recovery. *Case 169.*—The Glasgow.—A lad, aged 14. Primary amputation at the shoulder-joint. Recovery. *Case 170.*—The Glasgow.—A man, aged 23. Primary amputation for crushed wrist. Recovery. *Case 171.*—The Glasgow.—A man, aged 31. Primary amputation at the shoulder-joint. Recovery. *Case 172.*—The Glasgow.—A lad, aged 13. Primary amputation at the shoulder-joint. Recovery. *Case 173.*—The Glasgow.—A man, aged 31. Primary amputation through the forearm. Recovery. *Case 174.*—The Glasgow. A man, aged 23. Amputation through the arm for an unhealed burn of fourteen years ago. Recovery. *Case 175.*—The Derby: Mr. Fearn.—A healthy boy, aged 11. Primary amputation through the arm on account of compound fracture. Recovery. *Case 176.*—The York: Mr. Hey.—A boy, aged 12. Primary amputation on account of crushed hand. Recovery. *Case 177.*—The Cheltenham: Dr. Wright.—A man, aged 35. Secondary amputation through the arm, on account of gangrene after a severe injury. Recovery. *Case 178.*—The Bradford: Mr. Poppleton.—A man, aged 44. Secondary amputation on the eleventh day, after a compound fracture of an arm previously affected by ankylosis of the elbow. Recovery. *Case 179.*—The Bradford: Mr. Parkinson.—A lad, aged 16. Primary amputation through the arm on account of severe injury. Recovery. *Case 180.*—The Bradford: Mr. Meade.—A man, aged 42. Primary amputation of the left arm, and of part of the right hand. Recovery. *Case 181.*—The Bradford: Mr. Terry.—A man, aged 52. Primary amputation of the left arm. Recovery. *Case 182.*—The North Stafford: Mr. Alcock.—A man, aged 28, in good health. Primary amputation on account of compound fracture of the elbow. Recovery. *Case 183.*—The Dundee: Dr. Crockatt.—A lad, aged 17, in good health, admitted in consequence of severe injuries to both hands and forearms. Primary amputation of the right arm, and secondary of the left forearm one month after the accident. Recovery. *Case 184.*—The Liverpool Southern: Mr. Minshall.—A man, aged 21. Primary amputation through the forearm. Recovery. *Case 185.*—Addenbrooke's, Cambridge: Mr. Humphry.—A healthy man, aged 32. Primary amputation through the arm. Recovery. *Case 186.*—The Glasgow.—A lad, aged 17. Primary amputation at the shoulder-joint. Recovery. *Case 187.*—The Glasgow.—A lad, aged 21. Primary amputation through the arm. Recovery. *Case 188.*—The Glasgow.—A boy, aged 12. Primary amputation of the whole hand. Recovery. *Case 189.*—The Dundee: Dr. Crockatt.—A lad, aged 18. Primary amputation through the arm on account of compound fracture. Recovery. *Case 190.*—The Dundee: Dr. Crockatt.—A boy, aged 13. Primary amputation through the arm. Recovery. *Case 191.*—The North Stafford: Mr. Ball.—A man, aged 20. Secondary amputation through the arm, on account of gangrene after a compound fracture. Death from pyæmia. *Case 192.*—The Bradford: Mr. Terry.—A man, aged 56. Amputation on account of diseased elbow-joint. Death from exhaustion on the fourth day. *Case 193.*—The West Norfolk: Dr. Cotton.—A policeman, aged 49, in bad health. Amputation on account of extensive ulceration of the forearm and diseased bone. Secondary hæmorrhage from the brachial artery. The vessel was again secured, but death followed about two hours afterwards. *Case 194.*—The Glasgow.—A boy, aged 13. Primary amputation of the arm. Death from constitutional shock on the second day. *Case 195.*—The Glasgow.—A man, aged 58, the subject of disease of one kidney. Primary amputation through the forearm. Death on the eighth day. One kidney was found at the autopsy quite disorganized. *Case 196.*—The Glasgow.—A boy, aged 14. Secondary amputation through the forearm on the twenty-second day, on account of laceration of the hand. An abscess formed on the back of the head, and was attended by obscure head symptoms. Death on the 23rd day. No autopsy. *Case 197.*—The Glasgow.—A man, aged 27. Amputation at the shoulder-joint, on account of disease of the articulation. Death on the fifteenth day. *Case 198.*—The Glasgow.—A man, aged 31. Primary amputation at the shoulder-joint. Death from tetanus on the fourteenth day. *Case 199.*—The Glasgow. A man, aged 40, much injured by an explosion of gunpowder. Primary amputation at the shoulder-joint. Death from exhaustion on the second day. *Case 200.*—The Leeds: Mr. Teale.—A

man, aged 70, whose arm had been torn off by machinery. Primary amputation. Death from collapse the next day. *Case 201.*—The Leeds: Mr. Teale.—A boy, aged 18. Primary amputation through the arm. All did well for a fortnight, when symptoms of pyæmia set in. Death on the twenty-fifth day. Purulent deposits were found in the lungs and liver. *Case 202.*—The North Staffordshire: Mr. Garner.—A man, aged 68. Primary amputation for crushed hand. Death from exhaustion on the fifth day. *Case 203.*—The Liverpool Royal: Mr. Stubbs.—A healthy man, aged 30, admitted with many severe injuries, consequent on a fall from a house. Secondary amputation through the left arm in the seventh week. Pyæmia set in in the third week, and death followed. *Case 204.*—The Birmingham Queen's: Mr. Sands Cox.—A man, aged 43. Primary amputation at the shoulder-joint. Some ribs had also been fractured. Death from diarrhoea, &c., on the sixth day.

*Double Amputations.*—*Case 205.*—The York: Mr. Hey.—A man, aged 29. Admitted with both legs crushed by the passage of a railway train over them. Primary amputation of both below the knees. Death on the fifth day. *Case 206.*—The Liverpool Royal: Mr. Stubbs.—A seaman, aged 40, was admitted in a state of extreme exhaustion from starvation and exposure, and with gangrene on both legs. After some preliminary treatment it was determined to amputate. In each limb the leg was removed through its middle. He did well for a time, and the stumps healed, but death from exhaustion finally occurred on the 24th day. *Case 207.*—The Dundee: Dr. Crockatt.—A man, aged 26. Admitted with compound fracture of both legs from a railway accident. Amputation of both below the knees three hours after the injury. The patient did well for about ten days afterwards, when an abscess showed itself in the right thigh; a week later a second abscess formed in the left thigh. He sank exhausted on the thirty-third day.

*At the Hip-joint.*—*Case 208.*—The Glasgow.—A woman, aged 29, was admitted in May 29 with an aneurism of the right femoral artery in the middle of its course. Compression treatment was first employed, and with some benefit. Pulsation ceased in the tumour, but its size went on increasing, especially in a direction upwards. The existence of a malignant growth was strongly suspected, and amputation at the hip-joint was accordingly decided upon. This was performed on October 1st. Death from exhaustion consequent on hæmorrhage, &c., followed on October 16. At the autopsy the original aneurism was found consolidated, and around it was much grumous blood. Both the femoral and profunda arteries were much diseased.

SATURDAY, APRIL 17.

#### PROFESSIONAL ENCOURAGEMENT OF THE HOMŒOPATHIC QUACKERY.

When the Surgeons of the Middlesex Hospital claimed the "grateful acknowledgments" of the Profession for an American who professed to cure cancer, and who really did extirpate cancerous growths by what was erroneously believed to be a new mode of applying an old caustic, it became our duty to complain of this professional encouragement of an-

phism. And now that the Senior Surgeon of King's College Hospital has set the example of attending patients in company with Homœopaths, we shall not shrink from the task of characterizing such conduct as a direct professional encouragement of the Homœopathic quackery. We need not disclaim all personal feeling in the matter. If personal feeling were allowed to operate it would most certainly induce us to remain silent. But a broad professional principle is at stake, and we feel it to be a public duty to show the tendency of Mr. Ferguson's example to be far more injurious than that of Messrs. Shaw, De Morgan, Moore, and Henry; inasmuch as these gentlemen encouraged one man, while Mr. Ferguson supports a whole sect.

The Medical Profession has never claimed to itself the attribute of infallibility. On the contrary, it has ever admitted the difficulties in determining the causes of, and in devising the best remedies for, the diseases and injuries to which the human frame is liable. Without being wedded to any hypothesis, and being actuated solely by a search for truth, it has, from time to time, adopted such improvements as modern science may have suggested, and discarded such dogmas as the progress of knowledge may have proved to be untenable. Such, however, is not the case with quackery; for in proportion to the difficulties experienced and admitted by the investigator after truth, does the ignorant empiric disdain the fetters of legitimate reasoning, and arrogate to himself the exclusive possession of the power of healing. It is of little importance what garb the prevailing form of quackery may assume: whether the delusion consists in pretending to cure all diseases by drastic cathartics; in healing sores by a universal ointment; in remedying scrofula by the royal touch; in curing cancer with caustics; or in treating disease by the administration of inert and almost invisible globules of flint or charcoal. All are clearly forms of quackery. They originate in the love of the marvellous inherent in some portion of the human race, and are fostered by certain unscrupulous persons who turn the follies and weaknesses of mankind to their own advantage.

Of all the Protean shapes of quackery, Homœopathy is one of the most ridiculous and contemptible. Whoever will take the trouble to examine the doctrines of the Homœopathic school will be disgusted with their folly, shocked by their profanity, and outraged by their indecency; yet those who are acquainted with the history of the human mind, as developed in different countries and ages, will not be surprised that so foolish, profane, and indecent a system should have met with encouragement from a certain portion of the public. It may, indeed, excite a transient feeling of wonder, that amidst the blaze of intelligence which characterises the nineteenth century such a farrago of absurdity should have taken root at all, especially in a country like England; but it must be remembered that the most enlightened ages have been characterised by the prevalence of the grossest delusions, and the most cultivated intellects have sometimes entertained the wildest fancies and superstitions. Dr. Simpson reminds us that Lord Bacon believed a wound could be cured by applying a sympathetic salve to the weapon which inflicted it; that Boyle supposed he cured himself of an ague by wearing a medicated bracelet round his wrist; that Flamstead the Astronomer-Royal made a voyage to Ireland to be cured by an exerciser; that Dr. Hartley, the celebrated metaphysician, published a volume in favour of an alleged specific for gravel and stone, and himself died of the disease for which he declared that an infallible cure had been discovered; and that the British Parliament actually voted £5000 for the purchase of this same specific, which, when its composition was made known, was first ridiculed, and then forgotten! We may add that in our own times, people, otherwise rational, have been found to believe in the immaculate conception of Joanna Southcote, the divine mission of Joe Smith, and the

preposterous absurdity of clairvoyance, table-turning, and spirit-rapping. Bearing this in mind, one can understand what would be otherwise incomprehensible, that some weak people may actually believe in the tenets of the Homœopaths.

In justice and compassion something must be said in favour of the weak patients who are commonly the dupes of the Homœopathic and other quacks. These patients are frequently labouring under maladies, which, although perhaps fanciful, are yet the sources of intolerable torments. They readily fly for succour to any system which promises relief, and they will embrace the offer of this relief the more eagerly if the system proposed has in it something mystic and unintelligible, to say nothing of a spice of indecency or irreverence, which gives it a little more piquancy. Other patients again, labouring under chronic and painful ailments, have perhaps become weary of trying the resources of legitimate medicine, and fly as a last hope to the "certain relief" which quackery always promises, and never affords. To neither of these classes of patients would we deny any consolation which quackery may afford; but we would most energetically insist that quackery should be practised by quacks, and that patients in resorting to such assistance should be clearly aware of the character of the persons into whose hands they are about to fall; and that on no account should they be led to suppose that the extravagant doctrines professed by irregular practitioners are in any way countenanced by the Medical Profession.

With regard to the practitioners of Homœopathy, there is no more to be said for them than for any other quacks. They are usually either ignorant and illiterate persons, who, being too indolent to pursue a regular course of Medical study, adopt empiricism as an easy method of recruiting exhausted finances; or they are men who have failed in the legitimate practice of their Profession, and, as a last hope, have sought to earn a miserable subsistence by apostatising from the faith which they once professed. A few there may be who conscientiously believe in the truth of the doctrines which they practise; and these are probably feeble-minded persons, whose early education has been neglected, and who have never been instructed in the first principles of logic.

As for the system of Homœopathy itself, sprung from the disordered brain of a German mystic, it has been scouted with ridicule and contempt from nearly every region of the civilized globe. Although discarded by the learned in all nations, it still lingers among that small, though not unimportant, class of patients to whom we have already referred, and who, if they had not Homœopathy would embrace some other absurdity. In Leipsic, the cradle of globulism, the delusion has gradually dwindled away, and is now nearly forgotten; and throughout all Germany it has found no resting-place, except in Vienna, where a small hospital, entirely deserted by students, still pursues its obscure career. France has likewise repudiated the doctrines of the Homœopathic school, after giving them a fair trial; and we need not add that every University, College, and School connected with Medicine in our own country has indignantly denounced the fraud and folly of the dogmas and the practice of Hahnemann.

But, while regarding with an eye of compassion the dupes of the Homœopathic practitioners, and perhaps looking with pity upon some of the practitioners themselves, as being probably compelled by poverty to become empirics, we cannot but condemn, in the strongest language, the conduct of those members of our Profession who hold any professional intercourse with the quacks, or afford any countenance to their nefarious practices. The honourable and high-minded members of our Profession are quite aware that Homœopathy is a despicable compound of fraud and folly; that the principles on which it rests are utterly false and unsound; and that its

practice, if honestly pursued (which is not always the case), consists solely in leaving diseases to cure themselves; for no man in his senses can suppose that the Homœopathic globules produce any effect whatever upon the human system. Hence it has long been a point of honour with the Medical Profession to discountenance this, as well as any other form of quackery; and when one of our brethren, however humble his position may have been, has been asked to meet a Homœopath in consultation, he has generally pointed out to his patient that such a course would be inconsistent, not only with professional etiquette, but with common honesty; and if the patient remained deaf to his remonstrances, he has withdrawn from his attendance. But what can we say when members of our Profession, who are eminent in their position and distinguished for their talents, evince no repugnance to pursue a course of conduct which many a poor man would shrink from with disdain, openly meeting in consultation the globulistic impostors? or, what has the same effect upon the public mind, attending cases with them?

It is high time that this question should be answered. Let us have some definite plan of action agreed upon. Do not let us have young Physicians and Surgeons who are fighting their way in the world injuring their prospects by refusing to attend cases with the Homœopaths, and then find that some man of high standing has no such scruples. The juniors must not be charged with illiberality by the public, and told that the heads of the Profession are in the constant habit of meeting the Homœopaths on equal terms, that those who object are only actuated by fear and jealousy of the heresy, and are looked upon as carrying out in medicine the same spirit which led the Catholic Church to persecute schismatics. Let us have the matter fully and fairly discussed, and we can surely agree upon some plan of action without interfering in any way with the freedom of the public to encourage any quackery they please. Many among us would teach them to choose between quackery and Medical science, and select their attendants from the practitioners of one class or the other. They say that the two have nothing in common—that those must resign one who fly to the other. The natural consequence would be that those members of our Profession who encourage the quacks by consulting with them, or attending cases with them,—a distinction in which neither we nor the public can see a difference—would be left to the society of the companions they have chosen. They cannot serve God and mammon. Others think differently—and the question must be settled. Let it be discussed,—our columns are open. The views of three correspondents, expressing very different views of the question, will be found in other columns. Let it be discussed also at the branch meetings of the British Medical Association preparatory to some general resolution at the Annual Meeting in Edinburgh; and it should be well considered by our Medico-Ethical Societies, and the Practitioners of every large town or district. The Medical Practitioners of Reading have set the example, and, as may be seen in our advertising columns, have unanimously resolved: "That no qualified Medical man practising Homœopathy shall be met in consultation." It will be also necessary to determine the distinction between attending a case in company with or in consultation with Homœopaths.

#### THE WEEK.

Dr. Waller Lewis's report on the sanitary condition of the persons employed by the Post-office shows an increase of sickness among the letter-carriers. This is explained by the educational test of this class of persons being too high, and leading to the recruiting of the department, not from persons accustomed to active exercise and out-of-door occupation, but from classes of more sedentary habits. Thus the Civil

Service Examiners must lower the educational test, and look to physical qualifications. The Saturday half-holiday and the annual holiday, have been followed by a marked improvement in the health of the clerks. Such a result shows how much good service might be rendered to the State by a Medical Officer in a Public Department. It is high time that all our great public offices had such an officer.

The College of Physicians of London has, we understand, passed a Resolution, in conformity with which, in the future published lists of the names of the Fellows and Licentiates of the College, there will be appended to the names of those who possess it, the title of M.D., and the name of the University from whence the degree was obtained. This is a return to the ancient usage of the College, which was departed from some fifteen or twenty years ago. The College, it must be remembered, has only the power to grant a licence to practise; it has no power to grant degrees. It has, therefore, by this Resolution ceased to sanction by its silence the assumption of the title of Doctor by those of the Fellows or Licentiates who are not in the possession of a University degree. This is an act of justice to the different Universities, and quite in accordance with the liberal spirit exhibited of late years by the College.

The Memorial of the Militia Surgeons of the embodied regiments, asking to be placed on a permanent footing, has been answered by Government. General Peel stated in the House of Commons on Tuesday, in reply to a question by Mr. Brady, that he could not, "under present circumstances, increase the expense of the permanent staff of the Militia, which at present amounted to £159,000." Red tape can never get beyond £ s. d.; but the public must try to make obtuse officials understand the true economy of keeping up a full and effective Medical staff, not only for the Army and Navy, but for the Militia.

The Medical Reform question is being still further complicated by conferences, deputations, and petitions. The Corporations will not agree either to the Bill of Lord Elcho or to that of Mr. Cowper, and Mr. Headlam is to bring in a third. Lord Elcho's second reading is fixed for Wednesday, May 12, Mr. Cowper's for the following Wednesday, May 19. The College of Surgeons of Edinburgh have opened the ball by a petition against Lord Elcho's Bill, and others will follow the example. We shall have petitions during the next month for and against all the Bills, but it seems a pity to take any trouble in the matter, as any one of the three parties is quite powerful enough, without extraneous assistance, to defeat the other two. The Royal Commission seems, after all, the only practical solution of the difficulty.

The practice of puffing secret remedies is not confined to this side of the Channel, but prevails among our neighbours, where repressive laws, easily enough obtained, are not always found as easy of execution. It is the Academy of Medicine that is now complaining, for it is a common habit to advertise remedies in the newspapers, as having attached to them the approbation of the Academy, or as having been received by the Academy,—which for the public is much the same, although, in fact, the report upon them may have been condemnatory. It is against the law to advertise any secret remedies whatever, but this is evaded in various ways; and as to the fraudulent mention of the Academy's sanction, providing the remedy be not rigorously a secret one, the committee can only suggest the application of the

CHRONIC MANIA.

MANIA, CHRONIC, WITH AFFECTED SPEECH

law against the publication of "false news," which is a disgrace to the French Statute Book, and which has been the instrument of much tyranny. However, they are doubtful of even its elastic applicability, and call for new decrees or legislation. It will be found, on examination, that much of the boasted pre-eminence of the French in their arrangements for sanitary purposes and Medical police only exists upon paper.

We have more than once been informed by Medical visitors from the United States, that criminal abortion is by no means unfrequently practised by educated and duly licensed Medical men. We regarded the statement with incredulity; but the following resolutions passed by the Massachusetts Medical Society prove that it is only too true. The mere fact of a Medical Society having thus to protect its respectability shows the extent to which the practice has reached:—

"**SECRET REMEDIES AND CRIMINAL ABORTION.**—At a meeting of the Councillors of the Massachusetts Medical Society, held February 3, the following resolutions were adopted:—  
1. That the Massachusetts Medical Society deem it dishonourable in its Fellows to append their names in any way recommendatory of secret or quack medicines, and any Fellow so exhibiting his name shall be considered as acting in a manner derogatory to the dignity of a Fellow of this Society.  
2. That if any Physician or Chemist, through inadvertence or misapprehension, shall have been induced to give his recommendation or authority in any way to promote the circulation or sale of any secret or empirical remedy, he shall be expected publicly to disclaim or revoke the same.  
3. That the Fellows of the Massachusetts Medical Society regard with disapprobation and abhorrence all attempts to procure abortion, except in cases where it may be necessary for the protection of the mother's life.  
4. That when any Fellow of this Society shall become cognizant of any attempt to unlawfully procure abortion, either by persons in the Profession or out of it, it shall be the duty of such Fellow immediately to lodge the information with the proper legal officer, to the end that such information may lead to the capture and conviction of the offender.  
5. That no person convicted of an attempt to procure criminal abortion can, consistently with its by-laws, any longer remain a Fellow of this Society."

We have just received a pamphlet containing a mass of evidence upon the present sanitary condition of Jamaica, and upon the great need which exists of Medical and Surgical practitioners in that island. This evidence has been collected and published by the local Society for promoting sanitary, educational, social, and moral remedial measures for the existing evils; and the details present a picture which is truly appalling. During the continuance of the slave-trade the slaveowners paid a certain yearly sum for Medical attendance on the persons employed in the different plantations; and thus, on the one hand, the health of the negro was effectively watched, while, on the other hand, the Medical officers received a sufficient income to enable them to live and practise in the different districts of the island. That the sanitary condition of Jamaica was never in a very satisfactory state is abundantly proved by the frightful epidemics by which it has been ravaged from time to time, and especially by the late visitation of cholera in 1850, which was of so awful a character, and swept off so many thousands of the inhabitants, that Dr. Gavin Milroy was sent out from this country in 1851 to report upon the causes of the malady, and upon the preventive measures to be adopted in order to obviate its recurrence at any future period. To the Report then presented to the Home Government, and to the appalling facts recorded by Dr. Milroy, we drew attention in a review published in this Journal on the 13th August, 1853; and we especially recorded the deficiency which was then stated to exist in regard to the supply of Medical practitioners, the

causes of the deficiency, and the means by which a better provision of Medical skill might be procured. It will scarcely be believed that, according to the pamphlet now before us, Dr. Milroy's warnings and recommendations have been alike disregarded; the sanitary condition of Jamaica is as bad as ever; and with respect to several of its most populous districts, not only is there no adequate supply of Medical and Surgical aid, but there is none of any efficient kind whatever. The poorer classes of the population, too indigent to pay for Medical advice and medicines, too indolent to seek for them, or too superstitious to believe them of any avail, die in multitudes of curable diseases and injuries, or they aggravate their sufferings by having recourse to quacks and the arts of sorcerers. Hence we find it recorded by a number of trustworthy witnesses that a great many women die in childbirth; that abortion and infanticide are commonly practised; that numbers of children perish in their first dentition; that fractured limbs are ununited, and strangulated ruptures, which might have been relieved, prove fatal to the sufferers; that fevers and agues are allowed to run their course, uncontrolled by Medical art; and that thus the mortality from ordinary disease is indefinitely increased, while the prospects of the mischief likely to arise in case of the outbreak of another epidemic are such as must alarm every philanthropist. Medical men have been driven from the island by the inadequacy of their remuneration; and we are told as a positive fact, that at the present moment there are not more qualified Medical practitioners in the whole island of Jamaica than there were twenty years ago in the towns of Kingston and Spanish-town alone! Surely this is a state of things which calls loudly for redress; and some very excellent remedial measures are proposed by the local Society which has collected together the evidence to which we now refer. It is to be hoped, for the sake of humanity, that the recommendations thus made will be no longer disregarded, and that sound Medical assistance may be afforded to the inhabitants of this important colonial possession. Whatever may have been the advantages, in other respects, obtained by the emancipation of the negroes, it is very evident, from this pamphlet, that their sanitary condition is much worse at the present day than when they were in bondage to their taskmasters. The planters afforded the benefits of Medical aid to their slaves, but the abolition of slavery has obviated the necessity of such assistance; and whether from poverty, ignorance, indolence, prejudice, or the prevalence of fatalistic doctrines, the emancipated negro of Jamaica, in common with his coloured brethren, is deprived of nearly all Medical and sanitary supervision, and the consequent deplorable increase of mortality and suffering are facts which are now patent to the world.

### PRINCIPAL FEATURES OF THE TWO MEDICAL BILLS NOW BEFORE PARLIAMENT.

THE following summary of the two bills has been extensively circulated this week. It gives a very fair epitome of them.

*The Select Committee's Bill  
introduced by Lord Elcho.*

Puts an end to local jurisdictions, and establishes the right of free practice throughout the kingdom of registered practitioners.

Supreme authority to be vested in a Medical Council of the United Kingdom, to consist of the President of the Board of Health for the time

*Mr. Cooper's Bill.*

The same.

The Council to consist of one person chosen by each of the following bodies:—

The College of Physicians of London.

being, and twelve other persons appointed by the Crown, of which not less than nine shall be qualified to be registered as Medical Practitioners. Not less than two of the persons so qualified to be resident in Scotland, and not less than two so qualified to be resident in Ireland. Of these appointments, three are to be for the term of four years, three for five, three for six, and three for seven years. Future appointments to be for the term of four years.

The College of Surgeons of England.

The Apothecaries' Society of London.

The University of Oxford.

The University of Cambridge.

The University of Durham.

The University of London.

The College of Physicians of Edinburgh.

The College of Surgeons of Edinburgh.

The Faculty of Physicians and Surgeons of Glasgow.

The University of Edinburgh.

The University of Glasgow, two Universities of Aberdeen, and the Universities of St. Andrew's, collectively.

The College of Physicians, Ireland.

The College of Surgeons, Ireland.

The Apothecaries' Society, Ireland.

The University of Dublin.

The Queen's University, Ireland.

And six other persons, not being Members of Council or Office-bearers in the Medical Colleges or Societies, to be nominated by Her Majesty; four to be appointed for England, one for Scotland, and one for Ireland.

Members, representatives of Medical Corporations, must be qualified to be registered as Medical Practitioners. Term of appointment not stated.

The representatives of the Medical Corporations and Universities of England, Scotland, and Ireland respectively, and the members nominated by Her Majesty for such parts respectively, of the United Kingdom, to be Branch Councils in their respective parts for the performance of certain duties under the General Council.

The Council not to establish any Examination of their own. The Examining Authority to remain in the hands of the present Examining Bodies, but the Council to make Regulations regarding courses of study, age of admission, and Examination.

The Council to have power to appoint Committees of their own body, of not less than three, to perform certain duties in Scotland and Ireland respectively. Such Committees to include the Members residing in the kingdom for which they are appointed.

Two Examining Boards to be established in each of the three kingdoms,—the one appointed by the Council to examine in preliminary education all Students of Medicine who are not Graduates in Arts,—the other for examination in professional education. For England, the Professorial Boards to be appointed by the College of Physicians of London, the College of Surgeons of England, and, until 1865, by the Society of Apothecaries of London, and by the Universities of Oxford, Cambridge, and London. For Scotland, by the Colleges of Physicians and Surgeons of Edinburgh, by the Faculty of Physicians and Surgeons of Glasgow, and by the Universities of Edinburgh, Glasgow, and Aberdeen. For Ireland, by the Colleges of Physicians

and Surgeons of Ireland, and, until 1865, by the Society of Apothecaries of Dublin, and by the University of Dublin and the Queen's University: but the Medical Council to determine the total number of Examiners in each part of the kingdom, and alter the proportions in which the several bodies shall appoint, as they may judge proper. The Council to make all rules regarding courses of study, age of admission, time, place, and manner of examination, such rules to be laid before Parliament. Professional Examinations to be open to Members of Council, persons deputed by them, and persons registered under the Act.

All persons passing the preliminary and professional examinations to be styled "Licentiates in Medicine and Surgery," and to enjoy the right of free practice in Medicine, Surgery, Midwifery, and Pharmacy, in every part of the United Kingdom, and to be recorded in the Register of legally qualified Practitioners.

The Register to be alphabetical, and to record, in addition to the above legal qualification, whatever Degrees or Diplomas may have been obtained from a University or Medical Corporation.

Practitioners legally qualified before the passing of the Act, to be registered according to their qualification.

None but registered persons to be entitled to recover charges.

Only registered persons to be eligible to public Medical appointments, or to have their Medical Certificates recognised as legal documents.

Names of registered persons convicted of felony or misdemeanour to be removed from the Register.

The Medical Council to prepare and publish a British Pharmacopœia.

The College of Physicians of London to be empowered to surrender its present charter, and to accept a new one, constituting it the Royal College of Physicians of England.

The College of Physicians and College of Surgeons of Edinburgh also to have new charters, constituting them Royal Colleges of Scotland, and providing for the incorporation with them of the Faculty of Physicians and Surgeons of Glasgow.

The Council to determine what Certificates from the existing Examining Bodies shall be recognised as qualifications for admission to the Register.

A General Register to be established, the form in which it is to be kept to be left to the decision of the Council. But besides this General Register the Council to establish, if they choose, and in such form as they may judge fit, subject to the approval of Her Majesty in Council, separate or special registers of persons having Degrees, Diplomas, or special Titles in Medicine or Surgery.

The same.

The same.

The same.

The same.

The same.

The same.

The same, except that the Faculty of Physicians and Surgeons of Glasgow are left to make choice of whether they will remain separate, or unite with the Edinburgh College of Surgeons.

## PROGRESS OF MEDICAL SCIENCE.

## Selections from Foreign Journals.

## OBSERVATIONS ON SCARLATINA.

By PROFESSOR TROUSSEAU.

THE following are some of the most interesting points in M. Trousseau's clinical lectures on scarlatina:—

Scarlatina varies in form, appearance, and intensity, to an extent witnessed in no other exanthem. Variola is always variola, whether benign, distinct, or confluent; and to be recognised constantly by its characteristics. Measles observes always pretty much the same course, its diagnosis being simple, and its complications capable of being provided for. In scarlatina there is nothing fixed or regular, and its concomitant or consecutive accidents are foreseen with extreme difficulty. Years may pass without a single death resulting from the disease, when an epidemic may arrive which will commit greater ravages than cholera or typhus. Nothing of this kind is observed in variola or rubeola. There occur, indeed, from time to time, epidemics that are more fatal than others; but in the most innocent of these there are always found bad cases of variola; while even in those which are most destructive, slight cases are met with. Scarlatina takes on a character of benignity or malignity according to the genius of the prevailing epidemic.

The eruption appears in some patients four or five hours after the fever of invasion has set in, and does so very rarely after the first day. The cases in which the eruption is said to appear only on the third day must be quite exceptional, and are mostly to be explained by the defective examination of the practitioner and friends. It is generally on the face that we seek for the first manifestation of an eruption, and it is there we find it in rubeola or variola; but in scarlatina we should search for the earliest traces on the trunk, the belly, and bend of the thigh. It may be found there thirty-six hours before it exhibits itself upon the face and neck, and hence a cause of error in the date of its appearance.

The fever of invasion is very acute, and accompanied by a rapidity of pulse met with in no other exanthem. Before many hours have passed the patient complains of the throat; and if care be not taken this affection of the throat may be mistaken for a simple angina, and the treatment adopted for it may be highly injurious in scarlatina. When the malignant form of scarlatina prevails, while the pulse in the adult rises to 130° or 160° on the first day, nervous phenomena appear, such as excessive agitation, utter insomnia, and subdelirium. Such symptoms as these are met with in very few inflammatory affections of the throat, and are very seldom observed at the onset of other pyrexia: so that from the very first the scarlatina exhibits all its malignity:—this malignity of the first day being such that individuals may succumb before twenty-four hours have elapsed. In cases like this the young practitioner may be taken off his guard, and may be led into giving a too favourable prognosis. Suspecting the advent of scarlatina and being present at its onset, he may promise a speedy subsidence of the violent fever on the appearance of the eruption. All prognostications in this disease must be made with the greatest reserve.

The duration of the eruption is very uncertain, bearing, in this respect, no analogy to that of variola and rubeola. Commencing on the first day, it may still be very vivid on the twelfth or fourteenth, although generally it becomes paler towards the eighth or ninth. In simple cases it lasts five or six days only. It is by no means so uniform and constant in character as represented in books. When severe and confluent it has the appearance of a tincture applied to the whole surface, but in the more simple cases it consists in a multitude of minute, round, red points completely separated from each other, and differing entirely from the spots in measles. The peculiar red rash of scarlatina is also accompanied by ailiary eruption, which, even when not visible to the naked eye, feels to the touch like shagreen. It consists in minute vesicles, which in thirty-six or forty-eight hours become filled with a lactescent fluid, and is very seldom absent in confluent scarlatina. If we examine a scarlatina eruption with a magnifying-glass, we may be easily convinced it is

not of one uniform colour as in erysipelas, but consists in elevations that resemble an excessively close eczema.

It is the tongue, however, which presents the most specific appearance in scarlatina, and is, perhaps, as special as is the eruption in variola. The first day there is nothing peculiar about it, but the next, if the patient has been sick, it is of a deep green or yellow colour, the point and edges being of an excessively bright red. When there has been no vomiting, it is of a milky white at its posterior part. Towards the fourth to the fifth all the pasty appearance disappears. The tongue, now of a scarlet red, is swollen, painful, covered with projecting papillae, and peels by friction. Towards the seventh or eighth day it becomes smoother, but preserves its redness. By the ninth day the epithelium becomes evidently reproduced, but the tongue scarcely recovers its normal appearance before the twelfth day.

M. Trousseau protests against the doctrine usually laid down, that, when the eruption is vivid and comes out well, the patient runs less risk of suffering from the various morbid phenomena. On the contrary, he declares it to be a law in scarlatina as in variola that the gravity of the case is in direct proportion to the intensity of the eruption. In distinct variola life is in as little danger as in scarlatina with slight eruption; and the issue of a confluent variola is surrounded by as many perils as is that of a confluent scarlatina, in which the entire skin is of a vivid red. The more intense the eruption, the more serious are the symptoms, and the more guarded should be the prognosis.

The sore throat of scarlatina forms one of the most difficult subjects of pathology. It is easy enough to describe its ordinary appearances, whether in the grave or the simple form, but there is sometimes a form met with of the most formidable character, which sets all prevision at defiance. The patient may have seemed to be going on very well, the fever having abated, and the rash disappearing, so that the most favourable prognosis has been delivered, when towards the eighth or tenth day of the disease there appear swelling at the angle of the jaw, neck, and sometimes face, abundant stinking sanious discharge from the nares, sudden enlargement of the tonsils, great frequency and smallness of the pulse, delirium, coma, coldness of the surface—the patient gently expiring at the end of three or four hours. The nature of this affection is quite obscure, although it is probably referable to diphtheritic complication. In this form, where the angina comes on at the eighth or ninth day, M. Trousseau does not remember a single instance of recovery; while even in the gravest form of angina, commencing with the disease, and reaching its maximum from the fifth to the eighth day, it is scarcely ever fatal.

Desquamation commences where the eruption ceases; as for example at the cervical region on the sixth day, and on the trunk on the seventh, and it lasts about fifteen days upon the arms and legs. Its characters are best marked on the hands and feet, and it is useful to bear this in mind. On the trunk, the squamæ may vary in size from two or three millimetres to one or two centimetres in diameter; but on the legs and arms, where the epidermis is thicker, they may attain four or five centimetres. They are detached in large plates, as after erysipelas and phlegmon, the desquamation never taking the fine furfuraceous appearance as in measles. To see the latter we must look closely, or even detach the minute exfoliation by friction with the sleeve of a black coat. In scarlatina the squamæ are far more manifest, and cannot be mistaken.

Speaking of the accidents which may attend this period of the disease, M. Trousseau first alludes to the affections of the nervous system. The patient having entered into full convalescence, he suddenly becomes seized with vomiting as at the commencement, great agitation, and extraordinary frequency of pulse, death being preceded by convulsive or comatose symptoms. This terrible state of things may come on when you are quite at ease as to the issue of the disease; and that without any consecutive anasarca, albuminuria, hæmaturia, or other circumstance having happened to explain this fearful state to which children as well as adults are liable—so careful should we be in prognosis in an affection like scarlatina, which cannot be regarded as cured until long after all morbid manifestations have ceased, death in the course of a few hours being still even possible during convalescence. These nervous accidents coming on during the desquamatory

period are a hundred times more dangerous than those met with at the commencement.

Anasarca is especially observed in the medium form of the disease, and affects not only children who have been exposed to cold or other imprudence, but those who have been watched over with the most anxious care. So rapid is the infiltration in some cases, that within twenty-four hours the swelling may occupy the entire body, and attain a size not met with in chronic diseases, affections of the heart, or nephritis. In other cases it is limited to the face and extremities. Although it is true that children usually recover from this anasarca by the aid of hygienic measures alone, it is no less so that on some occasions they die. Pain in the head and confusion of vision are complained of, and then convulsions are imminent. These may sometimes be warded off by seating the child with his head erect and his legs hanging over the bed, and administering a smart purgative. Generally, however, the attack of eclampsia is not to be prevented, and death may soon follow, not indeed the first time, although that is not very rare, but after several attacks following each other at short intervals.

Hæmaturia is an extremely common occurrence, but it is generally overlooked. When the blood is discharged pure, or only slightly changed by the acids of the urine, giving a blackish colour to the fluid, no mistake may be made; but when it is emitted in small quantity, and the urine is only of a rose colour, it will be probably overlooked. It may be detected by the precipitation of globules after long standing, and by the enormous quantity of albumen the urine contains. This is the albumen of the blood, and is not precipitated white, as in Bright's disease, but of a deep brownish colour.

Among the less known complications of scarlatina may be mentioned pleurisy and pericarditis. What is very remarkable, is that a pleurisy coming on at the decline of the disease takes on at once a malignant aspect, not only in the fact of the abundance of the secretion that follows, but by the rapidity with which it assumes the purulent form—by the 8th or 10th day from the commencement of the effusion. Suppuration does not take place quite so rapidly in the pericardium, which too is implicated seldom and at a later period than the pleura. It is to be remembered that rheumatism is of extreme frequency during the convalescence of scarlatina, which will explain why pleurisy and pericarditis are by no means uncommon. It is a curious fact that the rheumatism, notwithstanding the essentially malignant character of the exanthematous pyrexia, is of no great gravity, and may be cured without therapeutic intervention. Still, occasionally here, as in puerperal fever, we sometimes observe the most terrible form of rheumatism, which may be termed the suppurative form.

Bearing in mind the tendency of the exanthemata to run a fixed course, if scarlatina exhibits no serious accident, the less we do the better we shall treat it. All practitioners are agreed that the antiphlogistic treatment, as bleeding, active purging, and starvation, is more likely to prove injurious than useful; and even when really inflammatory affections supervene in the course of the affection, such as local phlegmasia affecting the tonsils, the lymphatic glands, or the cellular tissue, antiphlogistics still fail, probably on account of the septic character of the disease. All admit, however, that mild laxatives, producing two or three stools a day, are of use in moderating the violence of the febrile action.

During the acute period of the disease, when the patients die, they seem to succumb to the great modifications exerted on the nervous system. These may be manifested by the extraordinary heat of skin (produced, according to Bernard's experiments, through altered action of the splanchnic nerves), excessive vomiting or diarrhoea, delirium, coma vigil, or convulsions. In such cases, experience has amply confirmed the utility of the employment of cold affusions, as recommended by Currie. To put this bold treatment into practice, however, the practitioner must have arrived at such a point as to be able to make light of public prejudices and patients' fees. The treatment is not applicable to mild cases, for which mere expectation suffices, but only when the disease threatens to prove fatal, so that of three children thus treated, we may still lose two. "For a long time past I have employed these affusions, first in my private practice, and then at the Hospital; for I have never yet done anything in my life without having first tried it at my own risk and peril. I declare to you that I have never had recourse to them without deriving some benefit; and, so far from the affusions having ever done mis-

chief, even when they have not saved the patient, they have moderated the accidents and retarded the issue. In acting thus in private practice I certainly ran great risks, and I have often been ill recompensed for fulfilling my duty with this rigour. Still I have done it, and I continue the practice now that I have no more to fear, when I am getting old, and my position is established, and I can assume a responsibility that alarms me no longer."

As, however, the incurring such responsibility may entail a destruction of prospects that a young practitioner fears to risk, he may still, to a certain extent, follow out the treatment he knows to be best, while seeming to fall in with the public prejudices. Thus we may employ cold affusions in reality, although the friends of the patient believe them to be warm. Scarlatina, especially when malignant, is the disease of all others in which the temperature rises highest—to 41° C. in the axilla, for example. In case of affusions we apply lotions, at a temperature of 25°, which is an extremely cold temperature for a scarlatina patient, seeing that a difference of 15° or 16° exists between the surface of the body and the water applied to it. The patient being placed naked on the sacking, you pass a sponge, wetted in water at this temperature (which the friends regard as hot), very rapidly over the whole surface, and then, without drying the body, return him to bed and cover him up. An hour after the skin is found less arid, its heat less mordant, while there is a diminution in the frequency of the pulse. The other nervous symptoms also abate. After a very limited period, as two or three hours, the same group of symptoms appear, sometimes just as before. We must then repeat the lotions or the affusions, and so go on two, three, or four times a day, during five or six days in succession. As to the eruption itself, it is almost invariably found to be more vivid after the application; so that the friends, witnesses to the amelioration of the symptoms produced, urge the repetition of the lotions as long as peril continues.

Together with the affusions some internal remedies may be employed, foremost among which is carbonate of ammonia, given in quantities of from 30 to 60 grains per diem. Of musk, 3 to 6 grains are sufficient, though as many as 15 may have to be prescribed.

In the great majority of cases of scarlatina maligna there is nothing to be done for the throat itself; M. Trousseau having tried all the various means that have been recommended without benefit. Of all these he attaches the most importance to the careful application of hydrochloric acid. As to the form of angina which comes on about the ninth or tenth day, and is attended with diphtheritic complication, all local measures are useless, our chief aim being to keep up the powers by stimuli, food, and quinine.

The anasarca, when not extensive, is best treated by rest in bed, tepid drinks, and moderate diet. When the urine is bloody, acid drinks, uva ursi, mixed with syrup of turpentine, digitalis, and gentle laxatives, speedily produce relief. When the hæmorrhage is considerable, sulphuric acid and tincture of rhatany should be employed. When the anasarca is very extensive, and rapidly produced, convulsions usually occur, and death often follows. In this case we should give active purgatives, and keep the patient with his head erect, and his legs hanging down. Scarifications, or large blisters, may also be applied to the legs. When the convulsion comes on, musk, with a small proportion of belladonna, should be given. Another means M. Trousseau has frequently found the advantage of during the last twenty years, is compression of the carotids. When the convulsion especially affects one side, the compression should be especially made on the opposite carotid; while, when the convulsion is nearly equilateral, it should be made, first on one carotid, and then on the other; or, if it does not produce too much obstruction of respiration, on both at the same time. The compression should be continued for fifteen or twenty minutes on each artery, and as its maintenance is irksome, we should have the aid of an assistant, or instruct the friends in its performance. As soon as the acute accidents have disappeared, the eclampsia and the hæmaturia, which usually precede or accompany the anasarca, having passed away, we should give gentle diuretics, especially nitrate of potash and digitalis, giving at the same time, as recommended by Graves, iodide of potassium in large doses. But the anasarca and albuminuria of scarlatina, which are usually cured in two or three weeks, in certain cases only form the first stage of Bright's disease; and we

must always distrust a case when we find the albuminuria continuing after the acute symptoms have subsided. With respect to the pleural and pericardial complications which are met with at or about the same time as the scarlatinal anasarca, they are best treated by blistering and puncture of the pleura or pericardium. But it will be always found that, at the end of ten or twenty days, the effusion is converted into a lactescent or purulent collection. By means of iodine injections we may be still enabled to cure this dangerous complication in children, but we shall strive in vain to relieve it in the adult.—*Gaz. des Hôp.* 1857. Nos. 70, 79, 86, 96.

## PROVINCIAL CORRESPONDENCE.

### IRELAND.

DUBLIN, April 9, 1858.

At a sectional meeting of the Royal Dublin Society, held on the evening of the 26th ult., Dr. Edward Haughton read a very interesting paper upon hot-air baths, in which he treated of the several varieties of this bath in use in different countries, specially alluding to those of the Spartans, Romans, Turks, and native Irish. At the recent meeting of the British Association in Dublin, Dr. Haughton had made a communication to the Physiological section, in reference to the bath characteristic of the East, of which the essential part is the hot-air chamber. On the more recent occasion he showed that each of the above varieties agrees in placing the *summum bonum* of bathing in the production of free perspiration as the real cleansing agent; whilst ablation, whether in hot or cold water, is merely accessory, and is incapable of removing any but superficial impurities. Dr. Haughton made further general observations upon this subject; but it is to the description he brought forward of the hot-air baths in use among the Irish peasantry, and especially in the island of Rathlin, situated within four or five miles of the north coast of Ireland, and containing upwards of one thousand inhabitants speaking principally the Irish tongue, that I am desirous of at present calling the attention of your readers, considering it interesting to trace so marked an analogy between the habits of this simple people and those of the distant Orientals.

"Two varieties of sweating-houses, as they are called," said Dr. Haughton, "exist in Ireland; one kind being capable of containing a good many persons, and the other intended only for a single occupant. For a description of the former I am indebted to the Rev. Robert Gage, of Rathlin, Island, and for the diagram to Professor Haughton, the locality being interesting likewise in a geological point of view. Mr. Gage's letter is as follows:—

"In general, Rathlin is a very healthy place, and many of the people have attained to a good old age. Asthma is the most common disease, probably arising from the sulphureous vapour emitted from the turf or peat, with which it is strongly impregnated. Of late years, however, it has been less frequent, owing, perhaps, to the improved state of the cottages. Pulmonary consumption is very little known here. When the people are attacked with rheumatic pains, which are not common, they have recourse to a remedy of long standing, in the efficacy of which they have great confidence. In several parts of the island small buildings, called sweat-houses, are erected, somewhat in the shape of a bee-hive, constructed with stones and turf neatly put together, the roof being formed of the same materials, with a small hole in the centre. There is also an aperture below, just large enough to admit one person on hands and knees. When required for use, a large fire is lighted in the middle of the floor, and is allowed to burn out, by which time the house has become thoroughly heated: the ashes are then swept away and the patient goes in, having first taken off his clothes with the exception of his under-garment, which he hands to a friend outside. The hole in the roof is then covered with a flat stone, and the entrance is also closed with sods to prevent the admission of air. The patient remains within until he begins to perspire copiously; when, if young and strong, he plunges into the sea, but the aged or weak retire to bed for a few hours. This primitive vapour bath has been successful in removing pains of long standing, and people have come from

the mainland for the express purpose of trying its efficacy. It is not, however, applied exclusively to the cure of disease, for the young women not unfrequently resort to it after burning kelp to clear their complexions, especially if it should happen to be near the time of a Ballycastle fair. As the heating of the sweat-house is considered rather expensive, from the quantity of fuel required, a number of persons generally go in together, and but for the darkness of the place would present a sufficiently ludicrous appearance. The period of remaining in is at the discretion of the patients, but at the end of half-an-hour the house is generally cleared, and the fresh air once more admitted until its services are again required."

Sweating houses made to contain only one person are to be found on the borders of Fermanagh and Leitrim, and are also much resorted to by the peasantry; but it is needless to describe them, as they are essentially the same in character as the baths of Rathlin Island.

I am happy to say that the announcement of the formation of the New Sydenham Society has been extremely well received in Dublin; a large number of the Profession have already joined its ranks, and much satisfaction is expressed at the stated intention of the Council to propose for publication recent and practical works.

## GENERAL CORRESPONDENCE.

### PIROGOFF'S AMPUTATION.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a lecture on M. Pirogoff's modification of Mr. Syme's operation at the ankle-joint, by Mr. Spencer Wells, published in your Journal on the 20th March, he says in concluding his useful account of the Russian Surgeon's mode of operating:—

"I can tell you nothing of the results of the operation in this country, but I can repeat that in some of the cases where it has been said to have been performed, it most certainly was not done in the manner and with the precautions I have brought before you. Whether it has succeeded or not I cannot say, but I do say that in some cases it has not been fairly tested, and I think it is worthy of a full and fair trial."

It would thus seem that Mr. Wells was unacquainted with the fact that this operation had been performed six times in the Seaman's Hospital, and with results such as, in my mind at least, incontestably to establish its utility and advantages in certain cases.

The instances in question have been briefly recorded in a few notes on the subject by Mr. Croft, Assistant-Surgeon of the Hospital.

Believing that these cases represent the greatest amount of experience yet had of the operation in this country, and that the matter is one of considerable importance, I am desirous, with your permission, of drawing the attention of Surgeons to them, and to what I believe to be a very useful proceeding, with respect to whose merits I fully agree with Mr. Wells.

Of the six operations in question three fell to my hands; but in the cases of only two individuals, both the feet in one case having been removed at the same time. The result of these three operations was perfectly successful. Mr. Tudor, the very able resident Surgeon, performed the same operation in two cases, one of which subsequently died, and Mr. Croft has operated once,—his case also unfortunately dying very soon afterwards.

Two deaths out of five individuals would seem to be a lamentably large proportion; but in reality the operation had nothing to do with the death in either case. In one, it was performed in the forlorn hope of relieving a man who was much reduced by previous pain and discharge from diseased tarsus, and the subject of albuminuria, and who sank apparently from exhaustion, shortly after the operation; whilst in the other, as I am informed, at the time of its performance the patient was affected with painful swelling of one shoulder, which, on examination after death was found filled with pus. The pyæmia was clearly, therefore, not referrible to the operation, which in fact cannot, any more than that of which it is

a modification, be regarded as in itself at all of a dangerous nature.

With respect to the advantages of M. Pirogoff's procedure I need say but little, as they have already been noticed by Mr. Croft and Mr. Wells, briefly remarking that greater facility and rapidity of execution; less disturbance of the natural relations of the parts which are to form the cushion of support; a solid, instead of a hollow flap; and, lastly, a greater length of stump, amounting to at least  $1\frac{1}{2}$  inch,—are such recommendations as few will be found to deny, and against which nothing, so far as I can perceive, is to be opposed.

Some have feared that the section left of the calcaneum would not readily unite with the extremity of the tibia; but this fear is groundless. In the last operation performed by Mr. Tudor, union was found to be quite firm on the twelfth day. In the others, no record of this particular has been kept; but in my first case the man could support his whole weight on the stump within a fortnight, although it was some time afterward before he could walk about, owing to the occurrence of suppuration in the sheath of the flexor tendons,—an occurrence to which the operation at the ankle, performed either with or without complete ablation of the calcaneum, would seem to be obnoxious. This has been the case at any rate in my hands, and it has not been prevented even by the methodical application of compresses along the course of the tendons, as appears to have been suggested by M. Pirogoff himself, according to Mr. Wells. As regards the operation itself, it is one of so simple a nature, and Mr. Wells' account of M. Pirogoff's mode of performing it is so clear, that but few words are requisite; and I should not refer to it, did I not see reason to think that the operation, as performed by me, differs somewhat from that of the Russian Surgeon, with which, until the appearance of Mr. Wells' lecture, I was wholly unacquainted.

The differences between us, however, except in one particular, if I am not mistaken, are not very material. It is clearly of no consequence whether the upper or lower incision be made first. I have practised the former, commencing it below one or other of the malleoli, and causing the ends to join those of the plantar cut at an obtuse angle, so as to avoid the formation of projecting calli when the flaps are brought together. But a more important point concerns the direction in which the bone is sawn. If I understand Mr. Wells aright, it would seem that M. Pirogoff divides the calcaneum nearly in a vertical direction, indicated by the line C D in the accom-

panying figure, whilst I make the section in a more oblique direction from behind downwards and forwards, as shown in the line A B.

Whether in this I am in accord with the eminent Russian or no, I cannot say, but it seems to me that the latter direction is, at any rate, to be preferred, seeing that with this obliquity not only is a more extensive surface brought in contact with the cut end of the tibia, but the remaining portion of the calcaneum does not require to be rotated on its axis so far as would be requisite were the saw carried in the direction of the line C D. The tendo-Achillis consequently would not be so much stretched, and a portion of the heel naturally in contact with the ground would still remain the basis of support.

To show the kind of stump left after this operation, I forward figures of a back and side view taken from a cast of the first case in which I had occasion to perform it. The cast was made some weeks after the man was completely

recovered and had walked about with a leather shoe or without one, which he did just as often.

This man I have had an opportunity of seeing six or seven months after his discharge from the hospital and when he had been a voyage to sea, on which he was able to perform all the ordinary duties of a seaman.

I do not venture to express an opinion of M. Pirogoff's modification of Mr. Syme's operation, without some experience of the latter, which I have had occasion to employ five times, and in all but one with perfect success and the most satisfactory results. The single exception was in the case of a man who lost both feet from spontaneous gangrene dependent upon disease of the arteries. The left leg was amputated below the knee, and on his recovery from this operation the right foot was removed according to Mr. Syme's method at the ankle. About half the flap sloughed, but the remaining portion by careful dressing was made to afford a sufficient and very useful pad when the stump was fitted with a suitable shoe, a matter which involved some difficulty. These cases all occurred before I had heard of M. Pirogoff's proposal; and since then I have not had occasion to resort to the same operation, though of its great merits I have nevertheless the highest possible sense. And I am glad to have this opportunity of saying, that in its original conception Mr. Syme appears to me to have conferred one of the greatest benefits upon practical surgery that it has received in modern times; though this is saying no little when we remember the numerous other and most important contributions in the same direction, for which mankind is indebted to that eminent man.

In the demonstration of the fact that a useful flap may be made from the natural cushion of the heel, he is, I believe, wholly original, while to M. Pirogoff is due the credit of pointing out that in performing this operation it is not in all cases requisite to remove the whole of the calcaneum.

In this communication my object has been to aid in showing that this important modification of the original operation is easy of execution and satisfactory in its results.

I am, &c. GEORGE BEE.

Harley-street, April 7, 1858.

#### CONSULTATIONS WITH HOMŒOPATHS.

[To the Editor of the Medical Times and Gazette.]

SIR,—With reference to the important point raised by the case of the Stamford Surgeons, Mr. Fergusson, and the Homœopaths, I trust the Profession will express a very decided opinion.

In the first place, it is obvious at once that a regular Physician cannot meet or co-operate with a Homœopath. As to a Surgeon, it might be alleged that his duty is only to act *chirurgically*, in the etymological sense of the word. But if he admit this to be his position, he abrogates his character as a scientific practitioner. If he only uses the knife, or applies dressings and ignores constitutional treatment, which includes the use of internal remedies, he is not what one considers a well-educated, high-caste Surgeon. What becomes of the dogma that "Medicine is one and indivisible?" How can a well-bred Surgeon be the *collaborateur* of a man whom he must believe to be either a lunatic or a charlatan? If such conjunctions are observed by the laity, how can they fail to feel confused and perplexed as to the real position of Homœopathy?

As I wish to express my opinion, but do not wish to controversialize, I subscribe myself,  
April 14, 1858.

A PROVINCIAL PHYSICIAN.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have chanced to see the remarks upon the ethics of your Profession, in your Journal of the 10th inst.

If I, as a patient only, and not a Medical man, have any right to be considered in the matter, I should like to put the following case to you and your readers.

I have been for some time an invalid, and have been under the treatment of a duly qualified practitioner, whose system I doubt not has been orthodox, although I cannot say it has proved very beneficial.

In fact, I find he is considered one of the "old school," and while depletion and calomel have been his principal agents, he has employed in turn almost every drug in the Pharmacopœia, too often, I fear, using one as an antidote to another, and making my unfortunate constitution a perfect battle ground for rival remedies.

Well, Sir, after enduring this for three or four years, during which my annual expenses in doctor's bills and incidentals have been counted not merely by tens but by hundreds, my faith in orthodox physicing has become somewhat shaken, and while changing my residence I am determined not again to surrender my constitution and comforts to a repetition of the ordeal.

But what am I to do? I have made inquiry as to the Medical celebrities in my new locality, and find that there are three duly qualified practitioners, all enjoying high reputations for talent, one of whom, however, has seceded from the regular practice of medicine, and is, in fact, an Homœopathist.

Now I am not converted to Homœopathy: my sympathies and convictions have all been hitherto the other way; but still, having heard much of benefits said to have been derived by others, who, like myself, have been unduly dosed, I have been half tempted to try his system, not (I confess) with any great faith in its success, (except, perhaps, temporarily, from the relief to the system after undue tension,) but rather in the spirit of candour, and under the idea that it cannot be more destructive to my constitution, nor so much so to my banker's balances, as that under which I have been treated.

Now, I find that one of the regular Practitioners altogether refuses to meet the Homœopathist, even upon the separate grounds of medicine and surgery, or to use his skill in the latter department to allay the sufferings of any patient of the latter, unless he will first abjure Homœopathy. He gives me no reason, and attempts no refutation, but indulges plentifully in abuse of both the others. Of the one because he professes Homœopathy, and of the other for reasons which I shall presently explain. I am told his refusal is not only approved, but in a measure compelled, while his abuse is imitated by a majority of the Profession.

The Homœopathist is not only willing to meet the others upon their separate grounds, but to submit his Medical treatment to the ordeal of a consultation with a man educated in medicine, and one able to expose his fallacies.

The third gentleman has no such scruples as the first. Like Mr. Fergusson, and himself a man of undoubted skill and acquirements, and of good practice, he deems it his duty to allay suffering, no matter what extraneous circumstances may surround the sufferer; and although sufficiently impressed with the truth of the principles of his own science, to refuse to recognise the homœopathic system as being equally founded in truth, or to admit its Professors to consultation as equals, he yet allows his patients a liberty of thought and judgment, and in place of abusing the Homœopath behind his back, he does not hesitate to meet him on occasion as a gentleman (as he is by position and education), or to give him credit for sincerity, while he believes him to be mistaken. On this account this gentleman is abused by the first as virulently as is the Homœopathist. I would then, Sir, ask you and your readers—

1. Whether I am unreasonable when I say I have more confidence in the talent and principles of either of the two gentlemen last mentioned, than in those of the first; because the first forces upon me a misgiving that he would study his own interests and prejudices in preference to my health; or else that he is by nature a bigot, who would be likely to follow foregone conclusions in his mode of treatment?

2. Whether the Profession expect that I should allow myself to be debarred by any etiquette or artificial rules of theirs from consulting those in whom I have the more confidence, in preference to him who would arrogate to himself a superiority which I cannot recognise?

3. It may be worth while for the Profession to consider whether Homœopathy and other evanescent systems be not the natural growth of treatment such as I have described, and whether they do not derive undue importance and success from the indiscriminate abuse with which they and their Professors are too often met.

In my own case the result will probably be that I shall permanently consult the gentleman whose liberality and candour have served with me as an introduction to his talented

and enlightened treatment, of which I am already feeling the benefits; but had he observed the same tone as the first, I should have been more disposed to have faith in the Professor of Homœopathy (or any other Pathy, for that matter) than in him; and in this I believe that I should be only showing that sturdy independence which usually characterises the family of John Bull, who (depend upon it) will find means to free himself from the terrors of Medical excommunication.

April 13, 1858.

I am, &c.

Vox POPULI.

[To the Editor of the Medical Times and Gazette.]

SIR,—May I say a few words about Medical ethics?

Mr. Fergusson is brought before the Profession for having obeyed the summons of a Homœopath to attend a patient in Northamptonshire. I will at once declare my own conviction that Mr. Fergusson acted like a high-minded and honourable man in fearlessly rendering his valuable aid where it was required. Surely every one who professes to hold himself at the disposal of the public in sickness is bound to attend when he is wanted; he is bound to do that which he professes to do, and if he refuses to do this then is he dishonest, not when he does it. What matters it whether the requisition comes through a person of heterodox opinions or otherwise? The obligation appears to me equally binding. To "refuse to serve God because the devil bids you," is to make the devil's work very easy; he has but to preach sermons, and call on doctors to exercise their honourable calling.

Now it appears to me that every man should do what he professes: if he professes to attend for his fee only, then is he bound to attend when that fee is offered; if he practises his profession on the higher principle of philanthropy, looking, perhaps, for a higher reward, he is bound to attend to all, rich and poor, learned and unlearned, deluded and undeluded. Of course, no man in his senses, who is a disbeliever in Homœopathy, would attempt to consult with a Homœopath as to Homœopathic treatment; but if a Homœopath is content to forego his creed so far as to require the assistance of a practitioner of medicine (I speak in the Hippocratic sense—*Chirurgia medicina est cum ferro*), has any such practitioner of medicine a right to refuse it? In my poor judgment he has not, because *pro tempore* the homœopath is not a homœopath. I am also presuming that he possesses a legal qualification. Besides, has not the Homœopath a perfect right to be what he is if he finds, or thinks he finds, he can cure with his globules? Some answer that no man can be such a fool; and if he is not a fool he must be a knave—hard words these, though in very common use. But if we thus summarily dispose of the doctor's character, what shall we say of his patients? Are they all to be knaves or fools too—some of them don't look like it, talk like it, or act like it, and I know a good many, though I am very sorry for them—they always remind me of live bombs who won't allow their fuse to be put out, so that they are likely to go out with a crash any day in the week. These patients, to a man, firmly believe that the ten thousandth of a grain of nothing which was taken with so much circumstance cured their colic, forgetting the air, exercise, diet, moral influence, and altered habits, which assisted it. If the patients are so deluded, can we be surprised that doctors are too? Why, their conclusions are drawn from just the same data; and doctors, though a very clever race, are but men. Let us be kind, then, and treat our erring brethren with charity, try to correct them from the error of their ways, not scold and be angry—it is "weakness to be wrath with weakness." Let us bear down opposition like the gentle but strong wind which passes on to its allotted place undeterred by petty obstacles; the whirlwind is but an idler after all, bringing back the dust in their faces, and blinding the eyes of those who raise it. Let us cease to use hard names, and use instead hard arguments, especially practical ones. To wit:—

1. Since Homœopathic remedies are nothing, treat them as nothing, and let your patients take them or not just as they like: they will believe you are sincere in thinking their physic powerless if you do this.

2. When you are wanted by a Homœopathic patient, go and attend to him; do your duty as far as your patient will let you; responsibility must cease when he who has a right to do so relieves you of it by taking it on himself.

3. If you find an individual at a patient's house in the

double capacity of his friend and Homœopathic doctor, treat him as a gentleman, for he has as much right to be there as you have. The same invitation has admitted him which gives you your right to be there, and you have no other. Say to the Homœopath: "Sir, we agree not on physis, but if you be a good man and true, in God's name help me to set this broken limb." Do not go away in a rage, and leave the poor patient in his agony till the rail has brought a "Homœopathic surgeon" from London, the only place, it would seem, where such an anomalous production can be found.

I have offered my advice, sir, freely, perhaps too freely, and would now in my turn ask advice of others. If they like not my suggestions, will they tell me how I should act in the following cases:—

A man smashes his leg, his son divides his radial artery, and his wife has strangulated femoral hernia. They all with one consent hate physis as they do poison, and they will have none of it. Shall I let the first die of mortification, the second of hæmorrhage, and the last of intestinal obstruction, because of their unbelief? Suppose these three persons to be rank homœopaths (still nothingists, if you will pardon the word), am I to act differently in that case? Why?

I am, &c.

JUSTA AUT NIHIL.

#### MR. PAGET'S VIEWS ON PERINEAL SECTION.

[To the Editor of the Medical Times and Gazette.]

SIR,—In your last number are some observations on stricture of the urethra by Mr. Paget, and that gentleman, after referring to the question as to the tendency of the disease to increase, states,—“no instrumental treatment, unless it be the perineal section, will prevent the increase of strictures in those who will not live prudently.”

I am surprised to find that such a sound thinker and observer as Mr. Paget is, should labour under so grievous an error, as to suppose that the increase of strictures is prevented by “perineal section.” Even had we not experience to guide us, reason and analogy would teach us that section of the urethral canal, whether from within or without, is more likely to be followed by results which will convert what may have been only a simple contraction into a traumatic, the most severe form of stricture. Experience, however, which Mr. Paget will admit is our surest guide, furnishes us with ample proof, not only that perineal section will not prevent the relapse of stricture, but that the contraction which results from the operation will be more obstinate than it was before such treatment was undertaken.

I have related some such cases in my recently published work on stricture, and subsequent experience has confirmed the views therein stated in reference to this point. I have only this morning seen a patient upon whom perineal section was performed some years since. He was apparently cured; but in the course of time the old symptoms returned, and on examining this man, whose previous case I had been familiar with, I found his stricture had returned as badly, if not worse, than before, and although careful treatment has been pursued, the amount of dilatation which has been effected with the greatest difficulty has been but slight.

Very recently I saw a patient who was suffering from a stricture totally unpermeable, as verified after death; the urine passing by a fistulous opening. Some years before he came under my notice, his stricture was divided externally, nevertheless the disease returned in its utmost severity. I have before me a letter from the House Surgeon of one of the great provincial infirmaries, by which I am informed of the particulars of two cases wherein perineal section was performed some time since, in one instance by Mr. Syme, and where the disease has returned. My informant stating with regard to the second case now under treatment,—“The man has returned with a long, hard, impassable stricture, and several perineal fistulae.”

There are several matters in operative surgery, such as ovariotomy and lithotomy about which it is impossible to obtain correct data, because the unfavourable cases are not mentioned; and it is as difficult to get at the results of cases of perineal section, because “dead men tell no tales,” and those who survive the operation are generally lost sight of as soon as they are discharged the Hospital, or have paid their fee.

Of one thing, however, I have been able to assure myself,

after having been at great pains to inquire into the results of perineal section, that that Surgeon who trusts in this operation as preventing the increase of strictures labours under a most grievous error. I am, &c.

HENRY SMITH.

Caroline-street, Bedford-square, April 11, 1868.

#### HORSE TAMING.

[To the Editor of the Medical Times and Gazette.]

SIR,—As you have admitted the subject of horse-taming into your columns, I am induced to send you a communication. That the secret does not consist in the use of drugs of any kind has been authoritatively denied, oil of rhodium alleged to have been administered would have been easily detected from its odour. We have it also on the faith of the initiated that mesmerism is not the agent employed. Do the following extracts from Catlin's “Letters and Notes on the North American Indians,” throw any light on the matter? Describing the capture of buffalo calves, Mr. Catlin says:—

“I have often, in concurrence with a known custom of the country, held my hands over the eyes of a calf, and breathed a few strong breaths into his nostrils; after which I have, with my hunting companions, rode several miles into our encampment, with the little prisoner busily following the heels of my horse the whole way, as closely and affectionately as its instinct would attach it to the company of its dam.

“This is one of the most extraordinary things that I have met with in the habits of this wild country; and although I had often heard of it, and felt unable exactly to believe it, I am now willing to bear testimony to the fact, from the numerous instances which I have witnessed since I came into the country. During the time that I resided at this post, I assisted in bringing in, in this manner, several of these little prisoners, which sometimes followed for five or six miles close to our horses' heels, and into the stable where our horses were led.”—Vol. i. p. 255.

The same process is employed in subduing the wild horse when taken by the lasso. In connexion with this we find it stated:—

“He (the hunter) gradually advances until he is able to place his hand on the animal's nose and over his eyes, and then to breathe into its nostrils, when it soon becomes docile and conquered, so that he has little else to do than to remove the hobbles from its feet, and lead or ride it into camp.”—Vol. ii. p. 58.

It is elsewhere mentioned by Catlin, that it is breathing, not blowing, into the nostrils that is to be performed, and that it ought to be continued some time to ensure success. Will some of your readers who possess unruly steeds favour us with the result of so simple an experiment?

I am, &c.

ARTHUR LEARD.

48, Finsbury-square, April 13.

#### ON THE EMPLOYMENT OF LIGATURES

AFTER DIVISION OF THE INTERNAL RECTUS MUSCLE FOR THE CURE OF CONVERGENT STRABISMUS.

[To the Editor of the Medical Times and Gazette.]

SIR,—In my recent work on “Strabismus,” at pages 137-8, occurs the following passage:—“It is desirable that the cut edges of the conjunctiva should be brought into apposition with each other on the completion of the section; but as it is not always possible so to retain them without some mechanical appliance, Mr. Walton has lately adopted the plan of using ligatures for this purpose, and he speaks highly of the results.”

In reference to this passage, I have recently received a letter from Mr. Wilde of Dublin, in which he claims to be the originator of the practice in this country. “So far as I can remember,” observes Mr. Wilde, “I first used it (the ligature) in 1843, and I have employed it constantly since. I was about to claim originality for the invention, when Gulz visited me in 1844, and assured me that he had previously used the same means. At all events, I believe I was the first person to use the ligature, and published the fact in Great Britain or Ireland.”

Mr. Wilde has referred me to vol. xxviii. of the *Dublin Journal of Medical Science* for Nov. 1846, page 216, in which the practice is alluded to in the following terms:—"In favourable cases of ordinary strabismus I unite the wound in the conjunctiva by means of three points of interrupted suture, composed of exceedingly fine silk or hardess, a practice recommended by Cunier, but which, I believe, originated with Dr. Gulz, of Vienna."

Having no wish to do Mr. Wilde an injustice, I can have no hesitation in complying with his request to publish the foregoing statement. I may, however, be permitted to observe, that I did not claim for Mr. Walton the invention of the practice alluded to, but simply stated that he had lately adopted it. I am, &c.

C. HOLTHOUSE.

2, Storey's-gate, St. James's-park, April 9, 1858.

### GRAHAM'S SAW, IMPROPERLY CALLED BUTCHER'S SAW.

[To the Editor of the Medical Times and Gazette.]

SIR,—Justice to myself, and the respect I owe to your readers, and to the Profession, demand from me a reply to Mr. Butcher's last letter.

In my communications to you, Sir, which you have honoured me by inserting in your Journal, I have merely stated facts, but I trust they were expressed in courteous and respectful terms. The claim I have made for Mr. Graham is an honest claim. When I first addressed you I believed that Mr. Graham was practising somewhere in Northumberland, and would readily establish the claim I had set up in his behalf. I am now informed that his death occurred some years ago, but his relatives remember his invention, and have placed in my hands two saws which belonged to their deceased friend, displaying the invention progressing to its present state. I have been favoured with the following letter from Dr. Lawrie, Professor of Surgery in this University which is explicit regarding the inventor of the saw, and the time of the invention.

"18, Brandon-place, April 8, 1858.

"Dear Sir,—In reply to your inquiry regarding the saw which you claim as the invention of the late Mr. Graham, I beg to state that it was made and given to me by my late pupil and friend Mr. Graham, about the year 1832, that I operated with it in the Infirmary of this city in 1834, and that ever since I got it I have almost annually shown it to my pupils at my public lectures, pointed out its advantages, and used it in their presence on the dead subject.

"That Mr. Graham had another saw, if not more, of the same kind, I know from the circumstance of his writing to me after he had settled in the north of England, and telling me that he had had several amputations, and that he never used any other saw.

"I am, dear Sir,

"Truly yours,

"J. A. Lawrie."

"To Mr. W. B. Hilliard."

The saw referred to by Dr. Lawrie is the one put into your hands for the fullest inspection, it is the one also from which the woodcut was taken which Mr. Butcher charges me with having "traced" from a plate of the saw in "Druitt," and with having "ingeniously left out the ornamentation of the upper bar," so that the figure might appear to be original and not a copy,—a charge so gratuitous and offensive, that it is with reluctance I stoop to refute it; however, the under note from the artist will decide the originality of the drawing, and to its fidelity, perhaps, Mr. Editor, you will testify.

[The cut is an accurate representation of the saw sent to us by Mr. Hilliard.—Ed.]

"Glasgow, 7th April, 1858.

"I hereby certify that I executed a woodcut of a saw for Mr. W. B. Hilliard, from a saw provided by him for that purpose, and that the woodcut was an exact copy of the saw given to me.

(Signed) "ROBERT ARTHUR."

I thank Mr. Butcher for admitting that the saw figured in "Druitt" as "Butcher's saw;" the one emanating from Messrs. Fannin's establishment and named "Butcher's Saw," and the "Graham's Saw," which you received from me, are in every point of likeness the same saws. In this I cordially agree with Mr. Butcher, for they are both in principle and

outline without modification or variation the same saws; and I join with Mr. Butcher in asserting that one is a copy of the other, the precision of outline forbidding the supposition of their being inventions by two independent agents. The question then resolves itself into one of priority. Who first produced the saw? Truly not Mr. Butcher, for he only adopted a bow-saw for surgical purposes about 1851; certainly it was not "planned in Messrs. Fannin's establishment," for the plan of that house was a modification of the saw adopted by Mr. Butcher, "to render it more suitable for an amputating case;" and most assuredly it was not the one which "Druitt" figured about 1854. Without a shadow of a doubt, Mr. Graham is the inventor of the saw, for he presented it as his invention to Dr. Lawrie in 1832; and if it cannot be proved that the saw existed prior to that date, I respectfully maintain that Mr. Butcher is bound in honour to join with me in requesting the Profession to name this saw (and the one "bearing so close a resemblance to it"), in all time coming, "Graham's Saw."

I have now concluded my part in this discussion. If any of your readers wish further proofs, I shall be happy to convey them by private letter; for I feel I have already occupied too much valuable space.

Sincerely thanking you for so kindly inserting my humble communications,

I am, etc.

WILLIAM BUXTON HILLIARD.

Instrument Maker to the Glasgow Royal Infirmary.  
65, Renfield-street, Glasgow.

### REPORTS OF SOCIETIES.

#### THE PATHOLOGICAL SOCIETY,

TUESDAY, APRIL 6.

DR. WATSON, President, in the Chair.

#### MR. LEGGATT exhibited a preparation from a case of SPONTANEOUS RUPTURE OF THE FEMORAL ARTERY.

A gentleman, 73 years of age, had been subject to gout for forty years; ten years ago had albuminuria, which entirely disappeared under treatment. For four or five years had been subject to giddiness; and had had numbness and uneasy sensation in his lower extremities, with diminished muscular power. For three or four months had had occasional attacks resembling slight angina pectoris. On the 13th of March he was seized with a fainting fit. He had felt weak and out of order for two or three days previously, and had during that time had some pain in front of the upper part of the left thigh; but there was no swelling or tenderness. On the 14th a hard, brawny, diffused swelling had appeared in the anterior half of the upper third of the thigh, with a decidedly prominent spot over the rectus femoris muscle, about four or five inches below Poupart's ligament. He fainted twice on this day. The pulse was quickened, and weaker than usual. The sounds of the heart were natural, but its action feeble. The urine was loaded with albumen. On the 15th ecchymosis had made its appearance on the front of the thigh, the swelling had increased, and there was evident pulsation in the prominent part of the swelling, and around it. No pulsation could be felt in the tibial or popliteal arteries. He gradually became weaker. Delirium set in on the 17th, and on the 18th he died at 8 a.m. The albumen had entirely disappeared from the urine before his death. There was no anasarca. All operative interference was rendered inadmissible by the shattered state of the patient's health. Mr. Cooper Hawkins saw the patient in consultation with Mr. Leggatt, and was present at the autopsy twenty-four hours after death. The general surface of the body was very pale. The circumference of the left thigh at its most prominent part was five inches greater than that of the opposite limb. There was slight oedema of the left foot and ankle. The ecchymosis extended downwards nearly to the ankle, upwards above Poupart's ligament in front, and over the glutei behind. On cutting through the skin of the thigh, the tissues beneath were gorged with blood, and loose coagula lay among the muscles. The sartorius, rectus femoris, vastus internus, and

the adductors were more or less broken up by the effused blood in the upper third of the thigh. A large perforation, about the size of a fourpenny piece, was discovered in the femoral artery, just before its entry into the sponenrotic sheath of the adductors. No trace of any aneurismal sac could be found. Small fragments of the fibrous coat of the artery were seen in the cellular tissue around the opening. The coats of the artery above the opening were much diseased, as were those of the profunda also. The external iliac was healthy. The pericardium was universally adherent to the heart, and the adhesions were in places converted into cartilage and bone. There was a large accumulation of fat at the base of the heart; but the structure of the walls, as well as of the valves, was healthy, or nearly so. The kidneys were congested and granular; the left was very much contracted, and the capsule very adherent. The preparation had been put up at the Museum of the College of Surgeons, and Mr. Quakett had reported to Mr. Leggatt that "the opening in the artery had a rough and gnawed appearance, as if proceeding from ulceration. Under the microscope, atheromatous deposit was discoverable with ossific plates. The artery above and below exhibited the same state of disease." There was a good deal of thickening of the external coat in the neighbourhood of the opening, but no appearance of increased vascularity. The case is interesting, as showing that ulceration or softening (whichever might have been the cause of the laceration) of the coats of a large artery, surrounded by dense and unyielding structures, may give rise to perforation, and fatal extravasation into the surrounding tissues, without the formation of any aneurismal sac. Mr. Leggatt stated that he had not been able to meet with the record of any similar case, and appealed to the members present to mention if any such had come under their notice.

Mr. BRYANT next showed a preparation from a case of  
**FRACTURE OF THE NECK OF THE FEMUR  
 WITHIN THE CAPSULE.**

Charlotte F., aged 69, an inmate of the Kent County Lunatic Asylum, upon November 20, 1857, was pulled off the edge of her bed by a child, and fell upon her right hip. There was some pain in the neighbourhood of the hip-joint, but more particularly in the knee. The shortening was very trivial, and there was no eversion of the foot. The woman could partly flex her thigh, though not without pain, and there was no effusion. Some difficulty was experienced in detecting crepitus, which was accomplished at last by an assistant extending and at the same time rotating the leg inwards. The long splint was applied and kept on for some weeks; a bed-sore, however, appeared, and from this she sank exhausted upon Jan. 8, 1858, seven weeks after the injury.

The specimen exhibited a genuine example of fracture of the neck within the capsule. The line of fracture was not direct, and upon one-half was not to be seen, unless some force were employed to separate the parts. The reparative process seemed to have progressed fairly, and if the bed-sore had not proved too much for her feeble powers, there seemed every reason to believe that perfect reparation would have taken place.

Mr. BRYANT also exhibited a specimen from a case of  
**IMPACTED FRACTURE OF THE NECK OF THE  
 THIGH-BONE.**

A woman, aged 62, an inmate of the Kent County Lunatic Asylum, when walking in the hop-garden upon September 17, 1856, fell upon her hip. When taken up there was found to be half an inch shortening of the limb, slight eversion of the foot, and power to flex the thigh; crepitus was only detected after several efforts. A long splint was applied for six weeks, and the patient regained the use of the leg. As she stood, there appeared no perceptible difference between the lower extremities. Early in August she was seized with an acute attack of bronchitis, which terminated fatally upon November 12, 1857, fifty-five days after the accident. The specimen presented was an excellent example of this form of fracture. The neck was completely driven into the shaft, and the small trochanter was fractured and pushed up; perfect union has taken place. The symptoms during life had been those generally present in such cases. Both the above specimens, with their histories, had been sent to Mr. Bryant by his friend Mr. W. Hills, of the Kent County Lunatic Asylum.

Mr. CURLING exhibited a specimen of

**A LARGE HYDROCELE IN THE RIGHT GROIN,**  
 the testicle being undeveloped and detained in the inguinal canal. It was taken from the body of a man supposed during life to be labouring under hernia. A large swelling in the groin was found to consist of a cyst with thin walls, which projected from the inguinal canal, through the external ring, and mounted upwards on the sponenrosis of the external oblique muscle. The testicle, which was lodged in that part of the sac situated in the inguinal canal, was quite small, like the undeveloped testicle of a child, but it was healthy and free from adhesions. The cyst contained about eight ounces of fluid, was sacculated, and had no communication with the abdomen. The left testicle, situated in the scrotum, was somewhat small, but sound in structure.

Mr. CURLING remarked on the difficulties of the diagnosis in this uncommon form of hydrocele, which he said might be readily mistaken for an irreducible hernia.

Mr. CURLING also exhibited a specimen of undeveloped left testicle, detained in the groin outside the abdominal ring, the right testicle situated in the scrotum being hypertrophied. He read an account of the case sent to him, with the specimen, by Mr. Page of Carlisle. Mr. Curling noticed the rare occurrence of hypertrophy of this organ.

Mr. SPENCER WELLS exhibited a  
**CYSTIC TUMOUR OF THE CERVIX UTERI RE-  
 MOVED BY THE ÉCRASEUR.**

The patient was married, 43 years of age, mother of seven children. Her last confinement was in January, 1851. Nine days after it she travelled from Scotland to England, and began to suffer from symptoms of prolapse, which increased gradually, until eighteen months ago the uterus passed external to the vulva. She suffered from extreme pain at the menstrual periods, and a troublesome profuse muco-purulent or sero-sanguinolent discharge between the periods. There was much general uneasiness, sensations of weight and dragging, with local tenderness and great derangement of the general health. She underwent a variety of treatment without benefit, and was latterly three months in one of our large Hospitals. She was discharged and told that her disease was incurable, and that she would "bleed to death" if the tumour were removed. She then applied to Mr. Spencer Wells, and was admitted into the Samaritan Hospital on the 3rd of March. Mr. Wells found the cervix uteri much enlarged, protruding whenever the patient was erect, its surface covered by the mucous membrane injected in patches, and raised by a number of cysts beneath. There was a viscid tenacious mucus passing from the canal of the cervix. There being no sign of malignant disease, and the general health of the woman suffering very much from the pain and irritation caused by the morbid growth, Mr. Wells determined to amputate the diseased portion of cervix by means of the *écraseur*. He did so on the 5th of March. The woman was brought under the influence of chloroform, the tumour drawn down by a vulsellum, and two harelip pins passed through the cervix to prevent the chain from slipping. The chain was then passed round the cervix about half an inch above the os, and gradually tightened. The cervix was nearly cut through when the chain broke,—whipcord was therefore tied round the undivided portions; but as there was no bleeding, it was removed again. The next day two or three ounces of clot came away, which was the extent of hæmorrhage. On the fourth and fifth day there was considerable abdominal pain and tenderness, which subsided under the use of linseed-meal poultices and morphia suppositories; and the woman was discharged on the 26th of March, complete cicatrisation having taken place, expressing herself as greatly relieved, and rapidly regaining her strength. Mr. Wells exhibited drawings of the tumour made by Dr. Priestley, with microscopic diagrams of its structure. He had not been able to find any description of a precisely similar growth. It consisted essentially in the development of a large number of small closed unilocular cysts in the proper uterine tissue. They are lined by the ordinary secretory epithelium, and were filled with clear viscid fluid. They were probably not adventitious formations, but merely an abnormal condition of the Nabothian vesicles and mucous follicles of the cervix.

Dr. PRIESTLEY said, that in this instance the cysts were developed in unusual numbers, and involved a large portion

of the entire cervix. Had the growth assumed a polypoid form and grown from the cervical canal, it would, doubtless, have been at once recognised as a cystic polypus; but the cysts being developed in the substance of the cervix itself, had given rise to a very unusual form of tumour. A section showed it composed of cavities varying from the size of a pin's head to that of a bean, and these were lined throughout by a glandular epithelium, thus differing from those of M. Huguier, where no distinct epithelial lining was observed. Perhaps if the cysts described by M. Huguier were chiefly simple or closed follicles distended and enlarged, those in this case were chiefly the altered tubular glands which opened into the canal of the cervix, and in the healthy uterus might readily be traced almost to its vaginal surface by boiling a portion in water, and making thin sections for the microscope. The divided cysts were found frequently to communicate with each other, thus representing sections of tubes, and were filled with a glairy mucus, in which epithelial debris and fat granules were present in large quantity. The cysts were imbedded in true uterine tissue, their epithelial lining having a subtending layer of wavy fibrous tissue.

## HARVEIAN SOCIETY OF LONDON.

THURSDAY, APRIL 1, 1858.

DR. HAMILTON ROSE, President, in the Chair.

### Dr. HANFORD JONES read a paper on THE THEORY OF ELIMINATION IN THE TREATMENT OF DISEASE.

The author remarked that, in reference to numerous diseases in which we had more or less certainty of the presence of a *materia morbi* in the blood, as the efficient cause of the symptoms, there was a marked tendency shown by many practitioners to regard the phenomena as of eliminative character, and to shape in some instances their practice accordingly. It was contended that in cases of poisoning by drugs or venomous reptiles, the kind of treatment found beneficial was not eliminative, but such as opposed the morbid agency; and also it was shown that if the vitality of the organs was vigorous many poisons could be resisted and prove innocuous, although they were certainly imbibed. The phenomena of the Exanthemata, of Fevers, of Melanosis disorders, of Syphilis, of Skin Eruptions, Boils, and Carbuncles, and lastly, of Rheumatism, were examined, with a view to the elucidation of the subject, and particular reference made to the therapeutic treatment found most effectual. The conclusions which the author arrived at were contained in the following propositions:—1. In the majority of instances in which we have reason to believe that a morbid material has entered the blood and is affecting the system injuriously, it is vain to think of expelling it by any therapeutic efforts. Nature must be left to deal with it as she will, and the only direct aid we can give her in this process is to admit pure air as freely as possible, so as to favour the pulmonary exhalation. 2. We are at the same time to watch carefully for opportunities of aiding nature in her conflict. If reaction is excessive, we must endeavour to lessen it; if prostration threaten we must support and tone. If secretions become morbid they must be improved, and generally we must be on the look-out to discover and meet any special requirement that may arise. If Nature is equal to her task, we are to take care not to interfere with her. 3. There are several disorders (especially skin eruptions) which simulate, so to speak, eliminative actions, but in which the morbid phenomena are capable of a different and better interpretation, and even the presence of a *materia morbi* is very doubtful. These are to be treated by endeavouring to quiet inflammatory virus, to soothe nervous irritation, and to tone relaxed blood-vessels.

In the discussion which followed the reading of this paper, Dr. H. Powell, Dr. Theophilus Thompson, Mr. Lobb, Mr. Ballard, Dr. Browning, the President, and Mr. Stewart joined.

**DEATH FROM CHLOROFORM.**—It is stated in the *Boston Medical Journal*, without, however, any particulars being furnished, that a gentleman, named McChesney, died suddenly at Toronto, Feb. 1st, in a dentist's chair, after inhaling chloroform for the purpose of having teeth extracted.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 7th inst. :—

ALLEN, JOHN, Longton, Staffordshire.  
ARNISON, WILLIAM C., Allendale, Northumberland.  
BACON, GEORGE MACKENZIE, Lewes, Sussex.  
CARSON, RICHARD B., Killyshandra, county of Cavan.  
DAVIES, HENRY H. Llandyssil, Carmarthen.  
GROVES, W. G., Maidencombe, Teignmouth, Devonshire.  
HARRIS, ABRAHAM, Gwennap, Cornwall.  
LLOYD, EDWARD H., Thornbury, near Bristol.  
LOCKWOOD, JOSEPH, Armitage-bridge, Huddersfield.  
SHIETLIFF, EDWARD M., Chiswell-street, Finsbury.  
TARDY, ELIAS N., Trinidad, West Indies.  
THOMAS, WILLIAM SMITH, Haverfordwest.

The name of WILLIAM BROUGHTON DAVIES, of Wellington, Sierra Leone, was omitted in the list of those gentlemen who were admitted members on the 5th inst.

Also, on the 9th inst. :—

ALLAS, JOHN LEONCE, the Mauritius.  
BLANDFORD, GEORGE FIELDING, Grove, Brompton.  
CREW, JOHN, Tetbury, Gloucestershire.  
DONNE, JEREMIAH MOULTON, Castle Cary, Somerset.  
DOW, JOHN, Keith, Banffshire.  
EATON, JAMES WILLIAM, Bingham, Notts.  
HEMSTED, HENRY, Whitechurch, Hants.  
PARRY, HENRY HITCHCOCK, Allington, Devizes.  
ROBINSON, ENOCH, Marsden, near Huddersfield.  
WYATT, ARTHUR, Bedford.

Also on the 12th inst. :—

ADSETTS, JOHN, Derby.  
BLACKLEY, CHARLES HARRISON, Manchester.  
DRAKE, JOHN JEFFERY, Newton-Abbot, Devon.  
GEORGE, HUGH, Chepstow, Monmouthshire.  
GRIGG, JOSEPH COLLINGS, Exeter.  
HARLEY, JOHN, Ludlow, Shropshire.  
JONES, EDWARD, Coventry.  
MIREHOUSE, THOMAS, Workington, Cumberland.  
OUGHTON, TYLER, Sutherland-square, Walworth.  
REED, ROBERT RHODES, Cambridge.  
ROBERTS, GRIFFITH WILLIAM, Clynog, Carnarvonshire.  
SENIOR, CHARLES, Bradford, Yorkshire.  
WILSON, FRANCIS, the Mauritius.  
WINKFIELD, WILLIAM BENJAMIN, Bedford.  
WOOD, WILLIAM JAMES, Exeter.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 8, 1858 :—

BARRATT, EDGAR, Sydenham College, Birmingham.  
BEALE, GEORGE BEWSHER.  
BROWN, HENRY OSMOND, Twickenham.  
DAVIS, HENRY ROBERT, London.  
DAY, FREDERICK AUGUSTUS EDWIN, Hambrook, Bristol.  
GEORGE, JOHN WINNALL.  
MULLAR, F. G. W., Monecourt, Brittany, France.  
WORTS, EDWIN, Colchester.

## DEATHS.

**BOYER.**—Baron Philip Boyer, the son of the celebrated author of the *Traité des Maladies Chirurgicales*, has just died, at the age of 56 or 57, after a short illness. He was surgeon to the Hotel Dieu, free agent of the Faculty of Medicine of Paris, and Officer of the Legion of Honour. He published, in 1831, a report upon the treatment of ulcers by compression, which mode has since then been generally adopted in France; and in 1836 he published a treatise on syphilis; but his chief literary labour was his edition of his father's great work, to which he contributed valuable notes.

**CHOMEL, PROFESSOR.**—The news of the death of this celebrated teacher, able practitioner, and esteemed man, has just reached Paris from his seat near Epinay (Seine and Ouse), where he died in consequence of a long and painful illness.

which had obliged him to abandon practice for several years past. We shall hereafter furnish some particulars of his career.

**EDWARDS.**—April 8, at King's-road, Windsor, H. Edwards, M.R.C.S. Eng., 1826; L.S.A. 1822, aged 59.

**GOODALL.**—Jan. 28, Charles William Goodall, of Shanghai, China, aged 29.

**LLOYD.**—Jan. 30, at Melbourne, W. W. Lloyd, L.S.A. 1836; late of Great Russell-street, Bloomsbury.

**PAGE.**—On the 12th inst., at Calne, Wilts., George Page, M.D., aged 76.

**TURNER.**—On the 9th inst., at 20, Regency-square, Brighton, James Turner, M.R.C.S., Eng., and L.S.A. 1836.

#### APPOINTMENT.

**Dr. W. B. Sealy** has been appointed Coroner for the Province of New Plymouth, New Zealand. Dr. Sealy is a Member of the College of Surgeons, and well known as a "Guy's man."

**MEDICAL STAFF OF OUR INDIAN ARMY.**—By general orders of the 12th of February, Dr. Cruickshank, Deputy-Inspector-General, is appointed to the medical charge of Artillery, Cavalry, and Engineers, and First-class Staff-surgeon John Tice is nominated to the Medical charge "of all Her Majesty's troops in the several Infantry divisions in the field," second-class Staff-surgeon Frazer acting as sanitary officer to the force.

**NEW YORK STATE INEBRIATE ASYLUM.**—The suggestions of recent writers here on Dipsomania seem to be about to be realized in New York State. An important Board has been chosen from among the subscribers for the purpose of determining the locality of the asylum. The amount subscribed at a short notice, amounts to 50,000 dollars. Among the subscribers are more than 800 physicians, 90 judges, 400 clergymen, and 1500 merchants. The largest Medical petition that has ever been sent to any Legislature for an appropriation has been sent to the New York Legislature on behalf of this object. More than 1300 physicians have memorialised that body in regard to the importance and necessity of the Institution.

**BORDEN'S CONDENSED MILK.**—The Committee of the New York Academy of Medicine appointed to examine into the merits of this substance have reported highly in its favour. They say, "they believe it to be what it purports to be and nothing more; viz. pure milk deprived of most of its water, and deficient in none of its nutritive elements. They believe it to be the best possible substitute for pure new milk that can be had in this or any other city; equally adapted to the wants of all conditions of life, and often a valuable auxiliary to the Physician, either in private or hospital practice."

**MORTALITY IN SCOTLAND.**—The Registrar-General for Scotland says—"61,925 deaths were registered in Scotland during the year 1857, being in the proportion of 202 deaths in every ten thousand of the estimated population, or 1 death in every 49 persons. It thus appears that the deaths during 1857 exceeded those of 1856 by 3469, but fell short of those in 1855 by 324. In so far as a three years' average can determine such a point, it would appear that the mean mortality in Scotland is below that of England. During the past three years, the mean mortality in Scotland has been in the proportion of 200 deaths to every ten thousand persons living; whereas, in England, the proportion of deaths during the same years has been 216 deaths to every ten thousand living. From this it follows, that had the mortality in England, during these years, been at the same rate as it was in Scotland, 91,392 lives would have been saved during that limited period—which would have more than covered all the losses in the Crimea."

**MARSHALL HALL'S "READY METHOD" IN CHLOROFORM POISONING.**—Dr. Burge, of New York, relates an interesting case in which chloroform was administered to a young man during an amputation of the thigh. Just as the last artery was tied, the patient ceased breathing, the pulse could not be felt, the jaw dropped, and he seemed really dead. The usual

means of restoration having been resorted to in vain, a vigorous application of the "ready method" was put into force. "About every five seconds we forced the air from the lungs, by grasping the thorax upon both sides and depressing the ribs. In the meantime, the natural elasticity of the thoracic walls caused them to rise sufficiently to admit fresh air to the interior. In addition to this we turned the patient suddenly upon his side and partly upon his face, and almost immediately back again, about three times in a minute." These procedures were continued for more than half-an-hour before it became certain that any sign of life was manifest. It was, indeed, forty-five minutes before the patient was sufficiently restored to speak. The restoration was, however, at last complete. It was afterwards found that the chloroform employed was highly impure.

**RE-VACCINATION OF THE FRENCH ARMY.**—Since the adoption of the regulations of 1848, which ordered the vaccination of conscripts and unvaccinated soldiers, the number of cases of small-pox has much diminished in the army, and the disease has lost much of its gravity. Still, although vaccinated soldiers have been found to be proof against sporadic variola, a first vaccination has not always been found a preservative during epidemic visitations; and the facts upon which the desirableness of revaccination is founded become more and more numerous. This operation practised as a prophylactic during several epidemics has been followed by the most favourable results, and it may be inferred that individuals who have shown themselves susceptible to a new vaccination would have been equally so to the epidemic variolous influence. Moved by these considerations, and by the advice of the Army Council of Health, the Minister of War has decreed that re-vaccination should be performed throughout the entire army. Accordingly the troops garrisoning Paris are marched in weekly detachments to the Academy of Medicine for the purpose of undergoing the operation.

**EPIDEMIOLOGICAL SOCIETY.**—A deputation from the Epidemiological Society, consisting of Dr. Babington (President of the Society), Dr. M<sup>r</sup>William (Secretary of the Society), Mr. Marson, Dr. William Camps, Dr. Seaton (Secretary of the Small-pox and Vaccination Committee), and Dr. Waller Lewis, had an interview with the Earl of Derby on Tuesday, the 13th instant, at the official residence of the First Lord of the Treasury, in Downing-street.

#### VITAL STATISTICS OF LONDON.

*Week ending Saturday, April 10, 1858.*

##### BIRTHS.

Births of Boys, 852; Girls, 790; Total, 1642.  
Average of 10 corresponding weeks, 1848-57, 1525.

#### TO CORRESPONDENTS.

*Canis Capilli.*—It has occurred.

It has been found impossible to comply with Mr. Housley's request this week.

Mr. Kern's letter is in type.

*Yeldar*.—Juniors call on seniors, and if it were not so, our correspondent should conform to local usages.

*Alpha* had better apply at the Samaritan Hospital, or the Hospital for Women.

Mr. Middlemore's paper on the Surgical Treatment of Glaucoma shall appear next week.

Mr. Case.—The notice alluded to was not sent to us. It appeared in a local paper, and resembled very much the letter signed *Discipulus* enclosed by our correspondent.

We have been compelled to defer a further notice of Mr. Symes' case until next week.

#### BLISTERS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In your number of Saturday last there is an article taken from the *Gazette des Hôpitaux* suggesting a new mode of treating blisters. Allow me through the medium of your journal, to submit to my Professional brethren a plan I have for some years adopted with great success; by it, the object is promptly attained, and in a manner I think very preferable to that proposed by M.M. Florry and Favre. A sponge dipped in hot water is laid for a minute or two on the part to be blistered; an evenly spread blister-plaster is then applied, every precaution being used to secure its immediate contact with the skin during the time it is on—if the patient be an adult, at the end of five, if a child, at the end of four hours, the plaster is removed, and a warm bread poultice applied for an hour; in this poultice, without pain or annoyance to the patient, the blister rises well, and is then treated in the usual manner. Since I have adopted this plan I have never had the slightest trouble in healing the blistered surface, nor have I witnessed the painful and mischievous effects often resulting from blisters. I am, &c.

WILLIAM EVANS.

Marine-terrace, Herne Bay.

#### PHOSPHATE OF ZINC.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—My attention has been drawn to a paragraph in your journal (*March 13*), stating, "It is to be regretted that Dr. Barnes having used it (phosphate of zinc) 'in every case' with success for the last two years should only just now publish it (the formula)."

I do not believe that any remedy is successful "in every case." Your correspondent has no authority for stating that I have claimed any such merit for the phosphate of zinc.

With regard to the "two years," I am sure your candid readers will not think the period too long for the investigation of the therapeutical value of a new remedy. I propose to extend my inquiries still further before obtruding a detail of my experience on the Profession.

I am, &c.

ROBERT BARNES.

13, Devonshire-square, N.E., April 12, 1858.

#### DOUBTFUL STATEMENTS OF PATIENTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—There is a vulgar proverb which says that it is a foolish bird which renders its own nest uninhabitable. This was suggested to me by reading in your copy of last week the notes of a case of aneurism taken by Mr. F. Jowers, in which is recounted that the patient "showed the swelling to various Surgeons at different seaport towns, and was treated for a bubo; leeches, poultices, and fomentations being applied to 'bring it to a head that it might be opened.'" Now Mr. Jowers is not the first by very many who takes a delight in recounting how the patient suffered previous mal-treatment before he came under their talented hands, but such observations are always unnecessary, and tend to lower the Profession in the eyes of the public. Allowing James Fawcett (the patient) credit for all he tells us, and believing that several Surgeons did call the swelling a bubo, how often have the most eminent practitioners made the same mistake? But do not believe the statement. Everybody knows how ready the poorer classes are to give the title of Surgeon, or even Doctor, to any one who sticks a red lamp over his door or a coloured bottle in his window, and I think it far more probable that the searinger sought the aid of some of these self-styled Surgeons who so infest seaport towns.

The Medical papers are read by hundreds of the "laity," and it does us no credit to be seen cutting each other's throats, even if our antagonist should have made an error in judgment, for, after all, it was nothing more. Trusting this hint will be taken in good part, I am, &c.

April 13, 1858.

T. J. W.

#### FOREIGN DECORATIONS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Would you be kind enough to inform the "Member of the Legion of Honour," whose letter appears in your last number, that the Sardinian Government made a special application to Lord Clarendon to be permitted to confer a decoration upon me for my services to the Sardinian forces in the Crimea; that Lord Clarendon refused, because I was not "entirely" employed in the service of the King of Sardinia. To refute this objection, a memorial, signed by 158 Physicians and Surgeons, was presented to Lord Malmesbury, who declined to do otherwise than what the late Government had done. I forwarded a copy of the memorial to Sir John Hall, late Chief of the Medical Department in the Crimea, whose opinion on its rejection is couched in the following words:—"Your memorial to Lord Malmesbury is a very good one, and I do not understand on what plea they object to your receiving an honorary decoration from the King of Sardinia for services rendered to his army in the Crimea." Exclusive employment in the service of a foreign Sovereign cannot be a valid objection, as there is not one of those who received either of the Sardinian Orders in the Crimea that was ever so closely engaged with the Sardinian army as you were." I am, &c.

J. VAUGHAN HUGHES, M.R.C.P. and S. Lond.

5, Pavilion Parade, Brighton, April 13, 1858.

#### CHLORODYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—If you and your readers are not quite sick of the subject of chlorodyne, I would ask this question,—Will the discoverer and manufacturer deny that chlorodyne contains chloroform, morphia, peppermint, sugar,

and gingerine? If so, I am prepared before any tribunal to prove that it does contain these ingredients, and no new alkaloid, and, moreover, that all the properties justly attributed to chlorodyne, can be accounted for by a mixture of the ingredients above indicated. It certainly cannot be tolerated that Messrs. Davenport and Collis Browne's denial of the truth of the analyses that have been made and published of chlorodyne can be received when it must depend upon some such equivocation as this—when the analyst finds sugar in chlorodyne, these gentlemen deny the truth of the analysis, because instead of sugar they use burnt sugar or treacle in the composition of their wonderful compound.

Nor will their triumphant reply to the analysts avail them anything with those acquainted with chemistry or pharmacy, namely, that the physical appearance of the mixture made from the recipe of the analysts is quite different to that of chlorodyne; and I am surprised that Mr. Davenport, who is practically acquainted with pharmacy, should put forth such a reply when every druggist's apprentice knows that the physical appearance of such a mixture as chlorodyne depends upon the order of mixing the ingredients and their proportions.

Had Messrs Davenport and Collis Browne remained silent respecting the analyses I should have allowed them to enjoy the advantage of their discovery without comment; but when I find them venturing to deny the truth of analyses bearing evidence of correctness, I cannot but regret that there is not in this country some competent tribunal empowered to reward the authors of useful discoveries and to expose mis-statements.

London, April 15, 1858.

I am, &c.

CHEMISTS.

#### COMMUNICATIONS have been received from

Dr. CONOLLY; Dr. SYMONDS, Clifton; Dr. DIAMOND; Mr. HOLTHOUSE; Dr. ELLIOTSON; Dr. BARNES; Dr. LEARED; Mr. LIZARS, Edinburgh; RESIDENT GENERAL, Edinburgh (See General Board of Health); Mr. RIVERS; Mr. WHITFIELD; Mr. FIELD; Dr. RYAN; Mr. HOUSLEY; Mr. EVANS; Dr. BAINES; Dr. MCWILLIAM; Mr. HILLIARD; Mr. SKALY; Mr. SYMES; Mr. WOOLCOTT; Mr. L. W. COURTENAY; Mr. GREEN; Mr. J. EARLE; Mr. H. BROWN; Mr. COUCH; Mr. JENKINS; Mr. BYERLEY; Mr. J. ELLIOT; Mr. DAVY; Dr. B. DAVIES; Mr. PRITCHARD; Mr. UNDERHILL; Dr. PARSEY; Mr. DRUMMOND; Mr. W. J. HUNT; Mr. MIDDLEMORE; Mr. WRIGHT; Mr. WHITE; Mr. SYMES; Mr. RIDGWAY.

## APPOINTMENTS FOR THE WEEK.

### April 17. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; Westminster, 1 p.m.; King's, 2 p.m.; Charing-Cross, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Invertebrata."  
MEDICAL SOCIETY OF LONDON, 8 p.m.: Dr. Burke Ryan, "On Some of the Circumstances influencing the Practice of Exposure and Child-Murder in Different Ages."  
ROYAL INSTITUTION, 8 p.m.: Edwin Lankester, Esq., M.D., F.R.S., F.L.S., "On the Vegetable Kingdom in its Relations to the Life of Man."

### 19. Monday.

Operations at the Royal Free Hospital, 1 p.m.; Metropolitan Free Hospital, 2 p.m.; Orthopedic Hospital, 3 p.m.

### 20. Tuesday.

Operations at Guy's, 1 p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Invertebrata."  
PATHOLOGICAL SOCIETY, 8 p.m.: Council at 7.  
ROYAL INSTITUTION, 3 p.m.: Mr. Lacaze, "On the History of Italy during the Middle Ages."

### 21. Wednesday.

Operations at University College Hospital, 2 p.m.; St. Mary's, 1 p.m.; Orthopedic Hospital, 3 p.m.  
MICROSCOPICAL SOCIETY, 8 p.m.

### 22. Thursday.

Operations at St. George's, 1 p.m.; Middlesex, 1½ p.m.; Central London Ophthalmic, 1 p.m.; London, 1½ p.m.  
ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Invertebrata."  
ROYAL SOCIETY, 8½ p.m.  
ROYAL INSTITUTION, 3 p.m.: Professor Tyndall, "On Heat."

### 23. Friday.

Operations at the Moorfields Ophthalmic, 10 a.m.; Westminster Ophthalmic, 1½ p.m.  
ROYAL INSTITUTION, 8½ p.m.; Colonel Henry James, "On the Geodetic Operations of the Ordnance Survey."  
WESTERN MEDICAL AND SURGICAL SOCIETY OF LONDON, 8 p.m.: Nomination of Officers for the ensuing Session; and Mr. Leggett, "On a Case of Spontaneous Rupture of the Femoral Artery;" Mr. Martyn, "On a Case of Croup."

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Removal of tumour from arm. By Mr. Fergusson.

Westminster Hospital.—The following operations will take place on Tuesday next, at 2 o'clock:—

Epithelial cancer of lip; stricture; application of actual cautery for disease of knee; Mr. Holt. Anchylosis of knee; Mr. Holthouse.

St. Mary's Hospital.—The following operation will take place on April 21, at 1 o'clock precisely:—

Vesico-vaginal fistula. By Mr. Baker Brown.

**Struve's Seltzer, Fachingen, Marien-**  
BAD, VICHY, and other MINERAL WATERS. Royal German Spa, Brighton. Under Her Majesty's especial patronage. Struve's Pump Room and Promenades, for the perfect dispensing of the most renowned Continental Mineral Waters, will be open from May to October, for the Thirty-fourth Season. The bottled Mineral Waters are sold throughout the year at the Pump Room, and by George Waugh and Co., Pharmaceutical Chemists to the Queen, 177, Regent-street (west side), London; and other respectable Chemists in London and the provincial towns, where a Prospectus, with the highest Medical testimonials, may be obtained, gratis.

CAUTION.—To distinguish these from all other Waters, each bottle is secured by a label and red-ink stamp, bearing Struve and Co.'s name.

## The Best Food for Children, Invalids,

and others.—ROBINSON'S PATENT BARLEY, for making Superior Barley-Water in Fifteen Minutes, has not only obtained the Patronage of Her Majesty and the Royal Family, but has become of general use to every class of the community, and is acknowledged to stand unrivalled as an eminently pure, nutritious, and light food for Infants and Invalids; much approved for making a delicious Custard Pudding, and excellent for thickening Broths or Soups.

ROBINSON'S PATENT GROATS, for more than thirty years, have been held in constant and increasing public estimation, as the purest farinæ of the oat, and as the best and most valuable preparation for making a pure and delicate GRUEL, which forms a light and nutritious supper for the aged, is a popular recipe for colds and influenza, is of general use in the sick chamber, and, alternately with the Patent Barley, is an excellent Food for Infants and Children.

Prepared only by the Patentees, ROBINSON, BELVILLE, and CO., Purveyors to the Queen, 64, RED LION-STREET, HOLBORN, LONDON. Sold by all respectable Grocers, Druggists, and others, in town and Country, in Packets, at 6d. and 1s., and in Family Cansisters, at 2s., 5s., and 10s. each.

## Williams and Son's Pure Glycerine

SOAP. Analysed by Dr. Hoffman, F.R.S., and Professor Redwood, Ph.D., strongly recommended by many eminent members of the Medical Profession, and favourably noticed by the following Medical Journals:—

THE LANCET.  
THE MEDICAL TIMES AND GAZETTE.  
THE BRITISH MEDICAL JOURNAL.  
THE MEDICAL CIRCULAR.  
EDINBURGH MEDICAL JOURNAL.  
THE DUBLIN HOSPITAL GAZETTE.

It is suited to all cases of delicate skin (whether arising from disease or otherwise), and is admirably adapted for nursery use. May be had of all respectable Chemists, Perfumers, etc.

SOAP-WORKS, CLERKENWELL, LONDON, E.C.

## Clarke's New PATENT PYRAMID NIGHT LAMPS.

Tin at 1s., Lacquered or Bronzed, 1s. 6d. each.

For Burning the New Patent Pyramid Night Lights. The most convenient, safe, and economical yet introduced.

Sold by all Grocers and Lamp Dealers, and wholesale by

S. CLARKE,  
55, ALBANY-STREET,  
REGENT'S-PARK,  
And by PALMER and Co.  
Clerkenwell, London, E.C.

## Dr. Caplin's Electro-Chemical Bath

ESTABLISHMENT, 9, YORK PLACE, BAKER STREET, PORTMAN SQUARE, for the extraction of Mercury, Lead, and other

immediate relief, and may in all cases be tried without danger. For the scientific demonstration of its modus operandi, see

The Second Edition, Just Published, price 1s., 8vo, of  
DR. CAPLIN'S TREATISE on the ELECTRO-CHEMICAL BATH, and the relation of Electricity to the Phenomena of Life, Health, and Disease.

London: W. FREEMAN, 69, Fleet-street; or of the Author, at his Eclectic Medical Establishment, 9, York-place, Portman-square. Gratuitous Consultations from Nine to Ten o'clock daily.

## The Medicated Cod Liver Oils,

comprising  
OLEUM MORRHUÆ CUM QUINA.  
OLEUM MORRHUÆ CUM FERRI IODIDO.  
&c. &c. &c.

Prepared only by SAVORY and MOORE, 143, New Bond-street.

## Liquor Pepsinæ.—A Convenient and

EFFICACIOUS PREPARATION BY  
SAVORY and MOORE, 143, New Bond-street.

## Great Saving in the Purchase of Six

GROSS of NEW MEDICAL GLASS BOTTLES and PHIALS, assorted to suit the convenience of Purchasers, at ISAACS and SON, Medical Glass Bottle Manufacturers.—London Warehouse, 6, Warren-street, Tottenham-court-road.

	s.	d.
6 and 8 oz., any shape, plain, or graduated	7	0 per gross.
3 and 4 oz. ditto	7	6 do.
1 oz. Moulded Phials	4	6 do.
1 oz. ditto	5	6 do.
1 1/2 oz. ditto	6	0 do.
2 oz. ditto	7	0 do.

No remittance required until the goods are received. Packages free. Delivered free within seven miles. Immediate attention to country orders. Post-office Orders payable to S. Isaacs and Son, at the Post-office, Tottenham-court-road, London. Bankers: Unity Bank.

## BROUGHAMS.

**Kindor, M'Naught, and Smith,**  
MANUFACTURERS, WOLVERHAMPTON, beg respectfully to invite the attention of professional men to their Improved Medical Broughams, as under:—

Width of Seat.	Weight.	Price.
3 ft. 5 in.	7 1/2 cwt.	85 Guineas.
3 ft. 6 in.	8 cwt.	95 Guineas.
3 ft. 7 in.	9 cwt.	100 Guineas.

The latter, including a segmental front, with seat for third person.

These Carriages are constructed, by the aid of machinery, of the best material, are of excellent workmanship, and particularly adapted to the wants of medical men, either in town or country. Drawings and other particulars forwarded on application.

## Solution Nitrate of Oxide of Glycyl,

used with success in the relief of SPASMS, HEADACHE, NEURALGIA, etc. by A. G. Field, Esq. F.R.C.S.

"I have not yet met with one well-defined case of neuralgic or spasmodic disease in which this medicine has failed to afford relief."

"As a direct sedative to the nervous system, without possessing any stimulating or permanently depressing qualities, without affecting secretion, together with its power of subduing muscular action, it appears to promise to become an invaluable agent in the treatment of a large class of nervous and spasmodic diseases."—Medical Times, March 30, 1858.

This powerful remedy requires the greatest care and exactness in its production. That the Profession may assure themselves they are using a preparation of uniform strength, each bottle will bear the signature of the manufacturers,

FERRINS and BARNITT, Operative Chemists, 23, Conduit-st., London, W.

## ELECTRICITY

**PULVERMACHER'S MEDICAL ELECTRO-GALVANIC CHAINS**—for Rheumatism, Indigestion, and Nervous and Paralytic Complaints, &c. &c. The profession have in these Chains the best, simplest, and most effective means of applying Galvanism. No pain is felt, and the patient can, without attendance, use them himself with efficiency. The popularity they have obtained in almost all parts of the world, and the numerous cures they have effected, together with the eulogiums passed upon them by the most eminent of the faculty, suffice for any further details. See the works of De la Rive, Becquerel, Duobonne, Pouillet, Ganot, Du Moncel, and the medical and scientific periodicals. Adopted by the Académie de Médecine, Paris, and by all similar institutions in Europe; also rewarded at the Universal Exhibition, £10,000 damages. Both the High Courts of England and France condemned Mr. C. Meinig (ex-agent) in this sum for infringing the inventor's rights. Let counterfeits therefore, be cautious.—Chains to be worn on the body, 5s. and 10s. 6d.; the 15s., 18s., and 22s. are the most useful. Free per post. Batteries, £1 10s. to £3.—J. L. PULVERMACHER & CO., 73, Oxford-street, (adjoining the Princess's Theatre,) London.

## Great Reduction in the Prices of New

MEDICAL GLASS BOTTLES and PHIALS at the Warehouse, 2, Upper Chancery-lane, near Rotherhithe-road, Islington, London, N. E. and H. Harris beg to submit the following prices for quantities of not less than 6 gross, assorted to suit the convenience of the purchaser.

	s.	d.
6 & 8 oz., any shape, plain or graduated	8s.	per gross.
3 & 4 oz., do.	7s.	6d. do.
1 oz. white moulded phials	4s.	6d. do.
1 oz. do.	5s.	6d. do.
1 1/2 oz. do.	6s.	do.
2 oz. do.	7s.	do.

No remittance required until the goods are received. Packages free. Delivered free within 7 miles. Immediate attention to country orders. Post-office orders, made payable to E. and H. HARRIS, at the Chief Office, London. Bankers: Union Bank of London.

## ORIGINAL LECTURES.

## GULSTONIAN LECTURES FOR 1858.

Royal College of Physicians.

By JOHN ADDINGTON SYMONDS, M.D. F.R.S.E.

Consulting Physician to the Bristol General Hospital, &amp;c.

## ON HEADACHE.

## LECT. II.

(Concluded from p. 393.)

*Mixed Headache.*—There is a form of headache often presented to our notice, into which both the hyperæmic and neurotic elements enter, and in which they are so mixed up as to render it difficult to say which of them predominates. There is hardly congestion enough to occasion pain, nor is the nervous disorder sufficient alone to engender a paroxysm. They are concurrent, and result from a common source. The neurotic susceptibility, and excitable circulation of some studious men will easily pass into this association of disorder, under the operation of excessive intellectual labour. I have often noticed the conjunction in ladies, whose headache has been generally of the purely nervous description, but in whom it has acquired a mixed character, either from the continued operation of causes acting on the brain, or by the addition of faults in the visceral functions productive of relative plethora. Perhaps the most typical example is to be met with in females at the change of life. At that period of migratory congestions the head comes in for its full share of visitation, and there is often at the same time a high degree of nervous susceptibility. Then we hear grievous complaints of pain, of fulness, and heat, and throbbing in the head, and the face looks as well as feels flushed, and the scalp and forehead are hot to the hand applied to them, as well as to the patient's own feelings. Her temper is irritable, and her emotions are wayward. Noise in the ears, dark spots, or bright coruscations, or tinglings and numbness, show the disturbance of the special senses. The patient complains of, rather than manifests, confusion of thought, and the sleep is broken and unrefreshing. All these troubles subside under different methods of cure, only to return again and again till the critical period has passed, and the body has grown (for it is a sort of development) into a new life and economy. With some, however, the brain is not to be carried safely through the crisis—mental derangement being left.

The combination of nervous and vascular irritation is strongly indicated by the agencies which excite or aggravate the headaches. Hot rooms, bright light, noises, prolonged mental application, emotional excitement, vinous and spirituous drinks, seem equally provocative. At the same time, the subjects are often made worse by causes of exhaustion, such as long fasting, loss of sleep, over-action of the bowels, and bodily fatigue. Not unfrequently, besides the irritability of the nerves and vessels of the brain, we find a like condition of the mucous membrane of the stomach and intestines, and articles of food and medicine are perpetually reproached, and not without reason, with being sources of disturbance.

But nothing seems more worthy of note in these and like cases than the general good condition of body, and the vigour of both the mental and the corporeal functions, in the midst of the continued liability to disorder, and the frequent recurrence of actual paroxysms. I have in my mind at this moment a gentleman who from early childhood was liable to sick headaches, as they were called, and who up to the present time suffers vertigo, sickness, irritable dyspepsia, and cephalalgia, more or less concurrently or interchangeably,—who has lived an active, struggling life, twenty years of which have been spent in one of our colonies,—and who now, at the age of 52, with hair unbleached, and with a ruddy complexion, and in frame and fashion *teres atque rotundus*, looks the very type of healthy, prosperous middle age.

*Neuralgic Headache.*—There is hardly sufficient reason for making a scientific distinction between neuralgic and nervous

headache. But there are one or two characters which dispose practitioners to apply the former epithet to certain cases. They are such as present the pain in so partial a locality as to suggest the idea of limitation to a particular group of nerves, as in clonus; or the pain takes a direction corresponding with the direction of a particular nerve, or set of nerves, as in frontal or occipital neuralgia; or it comes not only in paroxysms, but also with a disposition to periodicity. So far such cases do correspond with neuralgia in other parts of the body; but we have seen that nervous headache is pain beginning and ending in the nerves, and therefore that there is no pathological distinction as to the seat of pain. The cases alluded to, and usually distinguished as neuralgic, have, I think, this in common, that they oftener depend either on irritation transmitted from distant nerves or on causes of external origin. Thus the frontal and occipital headache are often produced by disordered stomach and bowels, the clonus by uterine irritation, the hemicrania by changes of weather, the brow-ague by malaria, or by currents of cold air, etc. The specially nervous headache, on the other hand, can more frequently be referred to agencies operating directly on the brain, whether mental fatigue, or vexation, or excitement, etc. But there are numerous cases in which there are no trenchant lines of demarcation. The nervous headache, instead of being continued and at the same time diffuse, or indefinite as to its locality, and dependent on internal causes, may occur paroxysmally, and be confined to one spot, and originate in a change of weather; and, on the other hand, the neuralgic headache may be so diffused, and present itself in so neurotic a subject, and be so traceable to mental causes, as to be indistinguishable from nervous headache. This diffusion of neuralgic pain, and consequent confusion as to its seat and origin, depends on what we formerly spoke of as radiation.

A strong example of this is presented in the hemicrania which is described so graphically and minutely by French authors, and which is popularly known as *Migraine*. But there is nothing in its pathology to distinguish it from neuralgic headache. Its character consists in the extension of the pain to the lateral half of the head, its intensity, its paroxysmal nature, and its liability to recurrence. For while the more common forms of neuralgic headache occupy the nerves of the first branch of the trigeminus, and those groups of vascular nerves which are distributed over the anterior part of the brain and its membranes, in the migraine the pain, though starting from the same point, is soon extended not only to all the nerves on the same side within the cranium, but also to the nerves of the face and the neck. Not only nerves of common sensation are involved, but also those of the special senses, and of motion, and the ganglionic nerves of circulation and secretion. For concurrently with the anguish, and sometimes antecedently, the patient suffers dimness of sight, or partial blindness, suffusion dimidians, noises in the ears, and even deafness; and we may observe corrugation of the brow, and twitching of the muscles of the face, fixing of the jaw, deep injection, even to the production of ecchymosis, of the vessels of the skin, darkening of the areola of the orbit, and outpouring of salivary fluid. For the extension of the pain in such cases we need, perhaps, seek no other medium than the radiation of the several centres, but with such evidence of implication of the functions of organic life, and with the known intermixture of nerves within the cranium, one can scarcely help suspecting that the diffusion of the disorder must be in some degree due to transmission of irritation from one ganglionic centre to another, from the ophthalmic to the sphenopalatine, the otic, the Gasserian, and the cephalic. If the vessels of the brain were in these attacks as much congested as are those of the eyelids and face, it is at first sight difficult to understand why fatal terminations are not more common. But the vessels of the brain must be capable of bearing a good deal of pressure without damage; else the debauch of the drunkard would oftener end in apoplexy.

*Sympathetic Headache.*—Many cases of headache, considered and treated as sympathetic, are really idiopathic, but they have had their most frequent exciting causes in remote organs. The truly sympathetic I take to be those cases in which the pain would not occur but for the irritation received from a distant organ. If a headache no longer return to a person after the removal of one or two decayed teeth, or after a change of diet which has corrected some fault of digestion, or after the function of menstruation has been restored from

an irregular to a natural condition, it is reasonable to conclude that whatever was the special susceptibility or fault of the cerebral nerves, it responded only to the impressions received from the distant organ. I believe, however, that the more closely we inquire into the history of cases of headache, the less reason shall we find for throwing the chief blame on the remote nerves.

But, on the other hand, it cannot be doubted that there are abundant examples in which the disorder of other organs is readily participated in by the head, perhaps in a degree beyond all other parts. The headache of indigestion—gastric, duodenal, and colonic—and the headache of uterine disorder, are very common occurrences. But the relation between the affections is of a complex nature; thus, before the headache has become so frequent an attendant on indigestion, the nervous system has been worn and weakened; and the same may be said of the other cases.

Patients themselves are apt to assert that their headaches are "all from the stomach," or "bile," or "liver;" and their conviction has a twofold origin—one in the sickness or other gastric disorder, or in the intestinal symptoms which accompany these attacks; the other in the relief which seems to ensue on the operation of medicines directed to the alimentary tube, as we have already hinted. But the sickness is oftener an effect than a cause, or even a concurrent, and the relief from purgative medicines admits (if true as a fact) of an obvious explanation, irrespective of the supposed disorder of the digestive organs.

The sympathetic cases arrange themselves naturally under the two heads to which we devoted some attention in the first lecture, viz. sympathy by radiation, and by transference. Thus as to sick headaches there is in the former case manifest dyspeptic disorder, in the latter it cannot be traced. The secondary irritation has effaced or supplanted the evidence of the primary. Thus even when the sick headache has had its exciting cause in some gastric derangement, it often happens that the sickness is still only an epiphenomenon in relation to the nervous pain in the head excited by the irritation of the gastric nerves. The matters vomited are simply the remains of food last taken, and the tongue is free from coating or fur, or unnatural redness. When once the morbid association has been set up between the two organs, it is difficult to say which is more in fault. Sometimes an error of diet has been committed, and the consequent indigestion brings headache with it. At another time the patient may have partaken of an irreproachable meal, but the light in the room has been too strong, the temperature too high, the air too close, the conversation too exciting or disturbing to the brain; and the morbid impression on the cerebral nerves being transmitted to the gastric, arrests the progress of healthy digestion, whether in the stomach or duodenum. From the time at which the disturbance manifests itself, it would appear that food imperfectly chymified has passed into the duodenum, and has lodged there, and that the impression on the nerves has recoiled on the brain, producing headache of the most distressing character, associated with nausea and vomiting, which continue till the bowels have freely acted, an event which in some persons is not to be obtained till a dose of calomel has been retained. The circle of vicious action in such a case has begun in the brain, passed to the stomach and the duodenum, then back to the brain, from which it again returns in the form of sympathetic vomiting.

There is a headache often called, in popular language, the bilious headache, which, were we to take the word of the laity for it, is a very common occurrence; but, I need not say, that "bilious" with the laity applies to any form of disorder characterised by anorexia and nausea. The only real cases of this affection, however, are those in which from duodenal obstruction or a more copious secretion than the duodenum can dispose of, bile regurgitates into the stomach, or accumulates in the blood; in the one case producing an acute headache, generally on one side of the brow, in the other giving rise to a dull headache, with more or less disturbance of the special senses in the form of suffusio dimidians, or of tinnitus aurium, and often with vertigo. A bilious diarrhoea attending or following the headache gives it a still more unequivocal character. But for one such case, I believe there are twenty in which the so-called bilious headache is nervous, with sympathetic disturbance of the stomach.

The headache attendant on constipation is often met with in practice, that is to say, the headache and the constipation

are the two facts placed prominently before us by the patient, because linked in his mind as cause and effect; but there is usually a long interval between those two events, filled up with agencies which might separately or collectively be quite adequate to the production of the headache, in one already liable to the disorder. In females, the morbid influence of a loaded colon or rectum is often directed first on the nerves belonging to the uterine system, and the headache which ensues is in direct sympathy with the latter.

As to uterine or ovarian headache, it is needless that we should dwell upon it; but, as far as my observation has gone, it is rare for headache to be produced by faults in the uterine function, unless there have been other agencies which have rendered the nerves of the brain irritable. If from previous debility, bad digestion, loss of blood, mental fatigue, worry, or vexation, or from constitutional disposition, there has been a liability to headache, then no cause is more easily provocative than some morbid impression on the uterine nerves; or, again, the long continuance of uterine disorder may have so worn down the nervous tone of the whole frame, as in this way to engender a predisposition to headache, as well as to neurotic disorder in any part of the body.

On the question which naturally presents itself, as to whether sick headache, bilious headache, and uterine headache, may not be in some cases engendered by the presence of noxious matters in the blood, severally owing their existence to functional faults in the abdominal and pelvic organs, we shall have to say a few words, under the head of toxæmic headache.

On the whole, I think it may be remarked as to headache sympathetic with gastro-enteric or with uterine disorder, first, that it may come in the train of these disorders—that is, that there have been marked indications of previous derangement in the digestive or uterine functions, so that headache, associated with or consequent upon such derangement, may be regarded as an extension of disease; for no disordered action can proceed long in any important organ without communicating its effects by nervous sympathy to other organs, and especially such disorder as essentially involves in some way or other the nervous function, which is in its very nature inter-nuncial: or, secondly, as we have already remarked, the headache, though consequent on the remote disorder, is so prominent as to divert attention from the source of irritation, as in the headache dependent on the presence of some undigested matter in the stomach or duodenum, unattended with gastric symptoms. Analogous instances occur in the headache excited by the irritation of a tooth which is not the seat of pain, though we know that headache also follows on disease of the teeth in the way of extension.

We see illustrations of the same principle in the headache which follows the application of some external agent to other nerves than those of the brain. I noticed in the first lecture the neuralgic headache excited by taking ice into the stomach, and also that which comes on a few hours after a person has been driving in an open carriage exposed to a cold wind. The impression of the cold on the nerves of the skin of the face produces no pain in those nerves; but the impression transmitted to the nerves of the brain excites a violent fit of headache.

In these cases of sympathetic headache, which are not disorders of extension, it seems to me that we cannot avoid the conclusion, that while there is a special proclivity in the nerves of the brain to ache, the sensibility is greater in relation to some impressions than to others. Thus, a person who could bear a prolonged fit of hard study, or a sudden shock to the feelings, or a strong light, or a loud noise, might suffer an intolerable headache from the irritation of a bad tooth, or from sitting in a draught of cold air. It is not wonderful that in such cases the remote irritation, when discovered, should be especially blamed; but we must still remember that the injury could not have been inflicted by the distant evil, had there not been a readiness in the cerebral nerves to be affronted by this particular impression. Yet it is fortunate for the subject that the susceptibility should respond to a single source of irritation, because the detection of the latter may sometimes be followed by removal or prevention of the pain.

A typical specimen of sympathetic headache is presented in that form, more than once adverted to, which supervenes on taking ice into the stomach. Within an hour or two, sometimes sooner, pain will come on in the supraorbital ridge

or the temple, attack the eye, dip down into the upper jaw, or extend itself over one lateral half of the head, acquiring the violence of a *tic-doloureux*. The origin of this pain <sup>proved</sup> unquestionably how an impression may be made on the nerves of a <sup>single</sup> organ, which, without producing any immediate inconvenience in <sup>that</sup> part, is conveyed to distant organs, and lights upon some particular set of nerves ready to take offence from such a cause, but which have shown their sensibility to disturbing causes in no other manner.

Of the circumscribed headache, dependent on dental irritation, I will venture to relate an instance which occurred to me many years ago. A gentleman had been suffering from pain in the right side of the head, deep in the middle region, for three or four months. It was sometimes acute, at other times dull. It had come on without any obvious cause. A great variety of remedial measures had been tried; local depletion, blisters, nervines, tonics, strict regulation of diet, and change of air and scene. As a last resource he had been advised to seek relief at some of the German spas, but before setting out he came to take my opinion on the subject. I was struck with the general healthiness of his look, and after questioning him fully as to the history of his case, as well as after examining him in the usual manner, I came to the conclusion that it was not a common case of headache, congestive, nervous, or dyspeptic. I examined his teeth, and found all of them in wonderfully fine condition, except the wisdom-tooth in the upper jaw on the right side, in which I thought I discerned a flaw. I persuaded my patient to go with me to a dentist, who speedily ascertained the unsoundness of the tooth, and at once extracted it. From that moment he was cured. I heard of him two or three months afterwards, and he had not suffered any return of pain. The following interesting case I read with great interest many years afterwards in Dr. Darwin's *Zoonomia*, a book which, had I been born fifty years earlier, I should, in common with ordinary students of medicine, have known almost by heart.

"Mrs. —, about thirty years of age, was seized with great pain about the middle of the right parietal bone, which had continued a whole day before I saw her, and was so violent as to threaten to occasion convulsions. Not being able to detect a decaying tooth, or a tender one, by examination with my eye, or by striking them with a teaspoon, and fearing bad consequences from her tendency to convulsion, I advised her to extract the last tooth of the under-jaw on the affected side; which was done without any good effect. She was then directed to lose blood, and to take a brisk cathartic; and after that had operated, about sixty drops of laudanum were given her, with large doses of bark; by which the pain was removed. In about a fortnight she took a cathartic medicine by ill advice, and the pain returned with greater violence in the same place; and before I could arrive, as she lived thirty miles from me, she suffered a paralytic stroke: which affected her limbs and her face on one side, and relieved the pain of her head. About a year afterwards I was called to her on account of a pain as violent as before, exactly on the same part of the other parietal bone. On examining her mouth I found the second molaris of the under-jaw on the side before affected was now decayed, and concluded that this tooth had occasioned the stroke of the palsy by the pain and consequent exertion it had caused. On this account I earnestly entreated her to allow the sound molaris of the same jaw opposite to the decayed one to be extracted; which was forthwith done, and the pain of her head immediately ceased, to the astonishment of her attendants."—*Zoonom.* vol. i. p. 451.

4. *Toxicemic Headache*.—The sympathetic headache is in a sense secondary, being subsequent in time to an affection of some other part of the body. But the headache to which it is better to restrict the term secondary is that which is only an effect of some general fault in the system; and it may be either the sympathetic headache of acute disease, such as fever, or it may be the local expression for the time being of a constitutional disorder, such as rheumatism, gout, or syphilis.

The headache of specific fever is consequent on the change in the blood: for whatever be the species of such fever, I presume that the constitution of the blood is in some degree involved. What may be the change in a simple catarrhal fever it may be difficult to determine, so evanescent is the change; and the headache that belongs to it will bear an explanation independent of the composition of the blood. In common catarrh the frontal headache would appear to be sometimes simply an affection of the nerves connected with the local

congestion of the Schneiderian membrane and of the conjunctivæ, and of the lachrymal glands. The degree of the headache is usually proportionate to the degree of local congestion in these membranes, and whether or not there is any congestion of the membrane lining the frontal sinus sufficient to account for headache, we may presume that the same impression on the ganglionic nerves which induced this active congestion may have produced pain in nerves which are so easily made to ache. But in epidemic catarrh or influenza there is strong presumption of the operation of an atmospheric poison on the whole system through the blood, and one of the earliest indications of its presence, or rather of the change in the blood consequent on its introduction, is pain in the head generally accompanied by pain in the back and limbs, and by extreme prostration. These headaches show how closely the nerves of the first branch of the fifth pair are associated with those in which the intra-cranial pain is seated, for there is nearly always more or less of pain in the eyeballs.

The headache of typhoid fever is, perhaps, the most decided instance of symptomatic headache; so prominent is it, and so rarely absent. As to its relative frequency in this fever as compared with other acute disorders, I cannot do better than recall to your recollection one or two statements of the accurate Louis. In the fatal cases recorded by him it was absent only in 4 out of 70. It began with the first symptoms, except in 3 cases, in which it did not appear till after the second, third, and fourth day. It usually ended when delirium or somnolence came on. He mentions the case of a woman who died on the twelfth day, and in whom the pain was so severe as to make her anxious for death, and it continued in full force till within two days of her death, and yet the brain presented no trace of disease. Of 87 cases of recovery, 57 were severe cases, and of these all had headache, except 2; and it was among the earlier symptoms in all but 8, and in these it did not begin till between the third and the twelfth day. Out of the 30 mild cases it was wanting only in 1. In 3 it did not appear till between the fifth or sixth day. In 1 only was it violent, and in that case only on the first day. Headache occurred only in half of the patients who died of other acute diseases, and it was rather less frequent in peripneumonia than in the rest; and in all it was less intense and of shorter duration than in typhoid fever.

Out of 57 cases of peripneumonia, headache was absent in 8. In the rest it appeared at the very beginning of the attack, and never lasted more than 8 days.

Out of 12 cases of variola, 11 had headache from the commencement, and it continued about six days.

In scarlatina it was wanting in 5 out of 19 cases. In no case severe, it began on the first day, with two exceptions, and lasted from six to seven days.

Of 13 cases of measles, 3 had no headache. It was one of the first symptoms in two-thirds of the cases, and it was slight in all.

Of 37 cases of sore throat (*Angine Gutturale*), only 4 escaped headache. It was present at the onset of the disorder, and lasted about five days. In rheumatism M. Louis observed it in only a third of his cases. Though generally of short duration, it continued in some of the cases a longer time than in any of the preceding affections.

Of 72 cases of pulmonary catarrh, 4 only were exempt from headache; but in a great number of the cases it was present only during the cough. In 24 cases it began between the fourth and twentieth day of the illness.

Of 84 cases of enteritis, 28 had no headache, and the absence of this symptom had no reference to the mildness or the severity of the attack. In 15 cases it appeared long after the commencement of the attack. Here, then, even as to the accompanying headache, we see a marked difference, says Louis, between the typhoid affection and true enteritis. But in these affections, as in all the others, there was an almost constant relation between the degree of the febrile movement and the frequency and intensity of the headache.

In lead-colic only a sixth of the cases suffered headache, which lasted two or three days, was nearly always of mild character, and seldom occurred early in the attack. The infrequency of headache in a disease of so painful a nature can only be explained, in M. Louis's opinion, by the absence of fever.

One cannot resist the conclusion, that headache in cases of acute disease has relation to the febrile condition

and if the essence of that state be held to be a change in the blood, the headache must be regarded not as sympathetic with the disorder of other organs, but as an effect produced by the blood on the nerves of the brain. In all febrile cases, whether purely febrile or inflammatory, the impression on the brain seems to be always of early date; and it is not necessarily the precursor of more serious affection of the brain. In typhus it is followed by delirium or somnolence, because the specific change in the blood in this disease seems to disturb the function of the cerebral molecules. The altered blood of inflammatory diseases affects the brain in like manner, but far less frequently than that of typhus. That the headache bears relation to the fever attendant upon the remote inflammation, and not to the local lesion, is further proved by the fact, that when the fever declines, though the inflamed part is still diseased, the headache has disappeared. That concurrently with the headache there is a certain amount of cerebral congestion, is probable from the relief which ensues on cold applications and on local depletion, and also on spontaneous epistaxis.

The headache which occurs later in the course of acute disease may be of different kinds; it may be of a very grave nature, as that which in conjunction with delirium occurs in acute rheumatism, not as a part of the symptomatic fever, but as denoting a more serious action of the blood-poison on the brain, and which occurs at the same time that the toxic agent is inducing inflammation in other organs, especially in the membranes of the heart.

A similar remark might be made on the headache of acute gout. In the pyrexial form it is only one of the symptoms, or coincidents of the attendant fever, but at a later period it may denote a more serious invasion of the brain by the gouty poison. There is another form of headache which often occurs in the gouty habit, and which is of a neurotic character, and usually assumes the character of hemicrania. The paroxysms are often intensely severe. It is scarcely needful to say that it must not be confounded with that pain in the lateral half of the head and over the brow, which is sympathetic with gouty scleritis. The headache which belongs to the rheumatic diathesis, and is commonly called rheumatic, is an affection of the fibrous and muscular tissues of the scalp, and is easily distinguished from other forms of pain in the head. In secondary syphilis the headache, though generally sympathetic with chronic periostitis or disease of the bone, is in other cases very like the neuralgic headache of gout, excepting that it is more diffused over the head, and that, like the pains which beset the limbs in these unfortunate subjects, it appears particularly at night.

Mr. Spencer Wells informs me that he often meets with a peculiar kind of headache dependent on secondary syphilis, the local cause of which he considers to be subacute frontal periostitis. The most striking symptom is that the pain may be brought on by the rim of the hat pressing on the forehead. Patients do not always notice this till they are asked the question; a fact which exemplifies what was remarked in our first lecture as to the indistinctness with which pain is referred to its source. Another and more serious form of syphilitic headache belongs to those cases in which the dura mater is the subject of this specific inflammation, and in which the brain itself is liable to be involved.

When treating of sympathetic headache in relation to gastric, hepatic, and uterine disorders, I remarked that we should have to consider it with reference to depravation of the blood attendant on such disorders. A priori, it would seem highly probable that the admission into the blood of some morbid product, or the retention of some substance which ought to have been eliminated in the disorders of the organs adverted to, might account for headache. Some digestive crudity, some element of the bile, some constituent of the menstrual secretion (organic chemistry might specify many possible substances), may be conveyed by the blood to the brain and act toxically on its nerves. There is no denying the probability of this, but the proof of the actual fact is by no means easy. Where headache is the principal phenomenon, such a mode of production is not required, after the evidence which has passed before us in proof of the excitement of pain in the head by impressions on the nerves of distant organs. But there are cases of by no means uncommon occurrence, in which the headache is only one of the symptoms, and in which there is a general disorder, though transient in duration. The acute dyspepsia, or the bilious derangement, or

the menstrual impediment, in such cases, has been attended or followed by a febrile movement. This febrile subsides after a few hours, when the alimentary canal has been unloaded, the hepatic and intestinal secretions increased, the catamenial discharge established; and with the feverishness the headache also departs. In such instances it is difficult to avoid the presumption that the cause of the headache was some toxic agent in the blood produced in the course of the functional disorder.

To speak of toxic agents from without, in relation to headache, would take us into far too wide an excursion. But I cannot help making a passing allusion to the production of headache by vitiated air. Many persons are immediately attacked with this pain when breathing a close atmosphere in a crowded room. Sometimes it is difficult to separate the influence of heat, vivid light, noise, gaseous combustion, and the accumulation of expired air;—and even when the last of these has been recognised as the exciting cause, it is not easy to say how much is due to carbonic acid, and how much to any other constituent. But one of the most original and distinguished of our recent physiologists has given us one clue to the source of irritation, in his observations on the effect of ammonia in the atmosphere, even when in so small a proportion as not to be detected by mere sense; I refer to Dr. Richardson's memoir on superalkalinity of blood, in the appendix to his admirable essay on the Coagulation of the Blood.

## ORIGINAL COMMUNICATIONS.

### ON THE TREATMENT OF HYSTERICAL PARALYSIS AND MUSCULAR ATROPHY BY LOCALIZED GALVANISM.

By R. M. LAWRANCE, M.D.

#### HYSTERICAL PARALYSIS.

In this form of paralysis the electro-muscular contractility is always normal, but the muscular sensibility either greatly diminished or wholly gone. The skin partakes of this loss of sensibility. Localized galvanization proves that in the muscles unaffected by the attack, the sensibility and contractility are quite normal, while those attacked by the disease are wholly insensible. That the insensibility of the paralysed muscles is not due to an anæsthesia of the integuments is proved by this, that under an insensible skin, the unattacked muscles were quite sensible when roused to action by the electrical currents. These attacks of insensibility of the skin and muscles most commonly follow a hyperæsthesia of the same parts, as if they had been exhausted by the previous sur-excitement. The power of volition sometimes returns while the sensibility may still be absent. These peculiarities in the history of this affection may be best illustrated by a few cases.

*Case 1.*—A patient who had been for some time subject to hysterical attacks suddenly felt violent pains in the shoulder without any assignable cause, followed by cutaneous hyperæsthesia, and terminating in insensibility of the skin and muscles; she was not in the least conscious of a sharp blow on the shoulder, and the muscular strength gradually diminished. A strong galvanic current was now applied to the muscles of the shoulder, causing them to contract powerfully without the consciousness of the patient. Sensation in the other muscles was normal, the skin of the right lower extremity was in some parts completely insensible; but the muscles were not paralysed, as a weak current sufficed to induce powerful contraction in them, and the electro-muscular sensibility appeared to be quite normal.

The want of the muscular sensibility, on being galvanized, did not depend upon cutaneous anæsthesia, as the galvanization of the healthy muscles produced in them healthy normal sensations, although the superlying skin was completely insensible. Anæsthesia of the skin and muscles followed a former existing hyperæsthesia at the same place, which often takes place in hysterical persons. Sometimes the anæsthesia

extends so deeply, that even the periosteum loses its electrical sensibility.

In general the voluntary movements are lost, but they may return, without the sensibility at the same time reappearing.

The therapeutic influence of localized galvanism over hysterical paralysis is not unfrequently most rapid in its action, but, unfortunately, we cannot rely upon its results being equally beneficial in all cases; for, while frequently in many of a very obstinate character a most successful cure has been accomplished, it has totally failed in others of a similar nature: hence fixed rules for the prognosis and treatment cannot be deduced from former observations.

As a general rule in hysterical paralysis, we must direct the electrical irritation to the affected organs individually, and continue the treatment for some time after the return of the voluntary motions, in order to establish the cure.

*Case 2.*—M. R. was suddenly seized with hysterical convulsions, which recurred every two or three months. The patient complained of a heavy shooting pain in the head, a sensation of continuous closing of the throat, pain in the chest, in the left side, above the pubes, and in the region of the lower dorsal vertebræ, pain on pressure on the shoulder and lumbar region, insensibility of the skin of the left side of the back and face, also of the limbs, which had previously been very sensitive and painful; insensibility of the lining membrane of the eye, nose, and mouth, on the left side, and on the same side weakness of sight, loss of smell and taste. There occurred also a loss of sensation in the palm of the hand and sole of the foot. For the last six or seven months the patient complained of muscular debility in the left arm and feet; she dragged her feet in walking, which now became difficult, or almost impossible. After exhausting all the usual remedial means, galvanism was resorted to on the 10th of October. By a few applications of five minutes' duration sensation was restored to the face: the mode of application was by cutaneous irritation with the electric hand. Very powerful currents, when applied by means of the metallic brushes, excited at first no sensation in the skin of the arm; the irritated parts, however, soon became red and hot, while a slight tickling, pricking, and lastly, an insupportable burning sensation was felt.

24th.—Sensibility of the skin normal throughout, and the patient has power over the muscles of the extremities. The menses appeared for the second time, though slightly. The patient was visited some months afterwards, and continued well.

Sometimes a single electro-cutaneous irritation suffices to cure hysterical paralysis, even when other means have failed.

In many hysterical patients the loss of sensation is greatest on the left side, and is especially accompanied by muscular debility in the left arm. The electro-cutaneous irritation seldom fails in these cases to restore the normal muscular power. In other cases, sufficiently numerous, the electro-cutaneous irritation appears to exert a greater effect than the muscular galvanization, most probably owing to a kind of reflex action. It is impossible to specify fixed symptoms (by the observation of which it may be decided) whether hysterical paralysis will be cured or not by galvanism; but, reflecting on those obstinate cases which have yielded to the therapeutic power of electricity, a great degree of confidence naturally arises in the use of this remedy, though it is occasionally shaken by its total failure in cases which seem precisely similar. Galvanism appears most suited to the paralytic form of hysterical palsy. Duchenne says, that in one hundred cases, he cured fifty, after every other method of treatment had failed. Electricity is usually resorted to as the *ultima spes*, and the number of cures effected by it would, in all probability, be much greater were it employed under the same conditions as other remedies. It is known that hysterical paralysis assumes different forms. Briquet has shown that the greater number of cases of paralysis of motion, of cutaneous hyperæsthesia, anaesthesia, paralysis of the senses, of hearing, smelling, taste, nearly always affect the left side; often, indeed, the paralysis is general, and sometimes it is confined to the lower extremities.

The sensibility of the skin was restored at the irritated points and returned, and became uniform after the electrical irritation. Sensation in the tips of the fingers, on irritating them with a wet conductor, was re-established in ten minutes, enabling the patient to distinguish pins from needles by the touch.

October 12.—Return of the menses after three months' cessation. The muscles were galvanized with very powerful currents, but still the patient did not feel the stimulus in the insensible parts, and it was only after a continued application that the electro-muscular sensibility returned, and she was now unable to bear even a weak application. Nevertheless the skin remained insensible. If the sensibility of the skin was excited at one point, the muscle immediately beneath became of itself sensitive. The sensibility was quickly restored in the left foot. The patient now feels the floor, but cannot walk, not being able to lift the foot, owing to a sensation of weight in the calf of the leg.

During the night the patient had two fresh hysterical attacks, and the whole body, with the exception of the left foot, again became insensible. A slight electro-cutaneous irritation sufficed to arouse the sensibility. Violent pains occurred in the head and chest after this attack, which, however, completely disappeared after the galvanization.

November 1.—Muscular galvanization for ten minutes. In order to establish the cure, the electro-cutaneous irritation was repeated from time to time.

10th.—Several hysterical attacks, which left no insensibility.

The sensation caused by the electrical irritation, even when it is not very painful, appears to those not accustomed to it so peculiar, that it may give rise to hysterical attacks; the more so as the imagination always excites a dread of such applications. It is necessary, therefore, to commence with very feeble currents, to accustom the patient to the remedy. A decrease of muscular sensibility requires the application of rapidly intermitting currents, which act upon the sensibility, and at the same time call out the return of the movements. This form of muscular galvanization is not always practicable in the hysterical, among whom many patients can bear the strongest and most painful muscular irritation, if the intermissions are but slow; rapid intermissions, on the contrary, always inducing an attack of hysteria.

We should in general direct the irritation to the individual paralysed muscles, without, however, neglecting the irritation of the nervous trunks. The excitement of the cutaneous sensibility is at times equal to the cure of hysterical paralysis. This is particularly the case when the cutaneous sensibility is very considerably diminished. Therefore we should only employ the electro-muscular galvanization during the first two or three sittings, in order to judge of the effect of this method of irritation on muscular paralysis. Should this yield considerably to the treatment, we may combine the local muscular galvanization with the electro-cutaneous irritation. If no improvement results in the condition of the paralysis, we should then apply the localized muscular galvanism, and the painful electro-cutaneous irritation will then be only required for the restoration of the sensibility of the skin.

#### MUSCULAR ATROPHY.

The progressive muscular atrophy is a disease, which up to 1849, all physicians regarded as constantly fatal. Once developed, its progress could not be arrested. It is looked on as hereditary, and terminates in some cases, at least, by an asphyxia caused by a destruction of the respiratory muscles.

Since that period Duchenne has been fortunate enough to arrest the progress of this afflicting and sad disease, so long as the fatty degeneration which accompanies the atrophy has not seized on the whole of the muscle; having proved in a way satisfactory at least to himself, that the fatty degeneration begins only in the last period of the disease, and that the atrophic period which precedes this is characterised by fibrile contractions and by the presence of irritability, which is of very long duration. The atrophic condition is ascertained by a simple inspection of the patient; the absence or the presence of the fatty degeneration, can be determined only by localized galvanization applied over the trunks of the nerves supplying the muscles with motor power. It was on such patients that Duchenne performed those interesting electro-physiological and electro-pathological experiments which the method of localized galvanization enabled him to do.

But it must still be confessed that the theory of this disease is most obscure, while, as yet, the mysterious therapeutic agent, whose powers we now discuss, has but partially succeeded in relieving the symptoms or in arresting that progres-

sion towards destruction which constitutes so prominent a symptom. The muscles become atrophied because they are not nourished; (a) or, as in the case of young persons, they are never developed. A friend informs me of two cases of this formidable disease, for which he was consulted, and for which every remedy (excepting localized galvanization) was tried in vain. They were the two sons of a family of wealth and rank, and both died about the same time, the one at about fourteen years of age, the other at twelve. There was a peculiarity in the limbs and form of the father of these young gentlemen which led my friend to ascribe it to an hereditary, or at least, congenital defect. Sir Charles Bell was consulted in the case, but with no advantage. Now, why this defective condition of the nutrition of the muscles? Monsieur Cruveilhier (b) calls the disease atrophic palsy, a name which, Duchenne says, gives not only a completely erroneous or incorrect idea of the complaint, which is, in fact, a disease of nutrition, but leads to a dangerous neglect on the part of the Physician of the stage of the disease, during which a cure is possible. It leads, in fact, to the idea, that the paralysis is the first symptom, and, accordingly in accordance, I think, with this view, has been devised and applied that theory which would ascribe to an atrophic condition of the anterior or motor roots of the spinal nerves (c) the disease we now consider. But the pathological condition of these nerves has not, I think, been fully proved in these cases, while it is difficult, in accordance with the admitted facts of modern physiology, to see in how far the nutrition of the voluntary muscular system can be so dependent on a sound state of the motor nerves. In conclusion, it may be remarked, that the volume of the muscular fibre is not diminished in atrophic palsy.

Every Physician knows that children, and more especially infants, are subject to a paralysis, which, at times, may be removed with great rapidity under a variety of treatment, at other times resists all therapeutic agents. According to the researches of Duchenne the form of paralysis, accompanied with a fatty degeneration of the muscular fibre, is distinct from that which may continue for a great length of time without any such degeneration taking place. In the former the paralysed muscles lose by degrees their contractility and electric sensibility. When these happily return, they do so along with their voluntary contractility. But should the symptoms persist, they are followed by deformities of all sorts; of the shoulders and trunk, pelvis, feet, etc. He concludes, from his observations, that the disease has its origin in the spinal marrow. Some are readily cured by a salt-water bath, and a few simple remedies; others resist all treatment. A Medical friend informs me that a case of complete paralysis of the lower half of the body which occurred in a child two years of age, was cured in a fortnight by sea-bathing, and never returned. Such cases must have occurred to all who have enjoyed an extensive field of observation; but so also must the reverse. Thus the prognostic becomes extremely uncertain, and ought to be given with every caution. Whatever view may, in the progress of pathology, be taken of the true nature of this complaint, it seems evident, that no remedy presents more rational hopes of success than localized galvanism; other forms of electrization are not safe in children, and ought not to be employed. Thus no one would venture to recommend in very young children the electrization by reflex action, which most assuredly would act on the nervous centres, so delicate and excitable in children; nor should we use the electro-cutaneous excitation, the galvanization by rapid intermissions. But no such objections can be made to localized galvanism as proved by repeated experience. Here, as in all other cases of paralysis, the first object is to determine what muscles possess and what muscles have lost the power of electro-muscular contractility; for, on its presence, though not wholly so, depend the hopes of a more or less speedy return of voluntary contractility, the object and aim of all treatment; and with it, to a certain extent at least, the nutrition and development of the muscles affected. Thus the electro-muscular exploration becomes at once a means of diagnostic and a method of cure.

## REMARKS ON THE SURGICAL TREATMENT OF GLAUCOMA.

By RICHARD MIDDLEMORE, F.R.C.S.,  
Consulting-Surgeon to the Birmingham Eye-Infirmiry, &c.

I HAVE had great pleasure in reading a most interesting paper in your Journal of the 27th of March, by Mr. Hulke, respecting the surgical mode of treating Glaucoma, now practised by Dr. A. von Graefe. I have not adopted the method suggested by that distinguished ophthalmologist, and am not willing to venture an opinion respecting its merits; but it is impossible to receive any suggestion from so cautious and so able a surgeon, without feeling every disposition to give the subject the most earnest attention. It must, however, be borne in mind that a surgical operation involving some risk of aggravating the evils it is intended to relieve, and which may be easily performed by skilful and well-practised surgeons connected with a London, or other extensive eye-infirmiry, cannot be so readily accomplished by surgeons not so situated, so that if the same end can be accomplished by a proceeding requiring less delicacy of manipulation, such method should undoubtedly be preferred. I believe we do possess such means, but before I say more on this question, let me be understood not in any way to recommend the neglect of such medical treatment as the variety, the severity, and the stage of the malady may require.

The surgical method in question was first suggested by me, as regards its special mode and principle of action, in my Jacksonian Prize Essay for the year 1831, and was repeated in my "Treatise on the Diseases of the Eye," published a few years afterwards, as the following quotation will testify:—"As there is a preternatural fulness of the globe, it may be desirable to puncture the sclerotics; and I should advise that this be done whenever there is much local pain evidently depending on the tension of the globe, and particularly when vision is nearly destroyed, and the opposite organ is becoming similarly affected. A very fine grooved needle passed into the sclerotics, at about three or four lines behind the margin of the cornea, will enable you to discharge a portion of the vitreous humour very readily, and with infinite relief to the patient. The only other circumstance to which it is necessary for me to direct attention is to pass the grooved needle obliquely backwards; for, unless you adopt this precaution, you may aggravate the patient's sufferings by displacing the lens. In one or two cases of glaucoma, where the muddiness of the vitreous humour has been evidently consequent on the inflammation of the parts which secrete it, I have, on the subsidence of the inflammation of the hyaloid membrane, discharged the greater part of the turbid fluid by means of a fine grooved needle, in the hope that the new secretion would be more transparent; and I am confident that I have more than once practised this operation with the greatest advantage to my patient's vision. This, then, is a mode of viewing the remedial agency of the evacuation of the vitreous humour perfectly distinct from that which contemplates merely the relief of tension of the globe." I have for many years been accustomed to relieve extreme cases of conical cornea by occasionally discharging the aqueous humour by means of a minute puncture of the cornea, and so for the relief of staphyloma at its early stage, and especially that form of it occurring after ulceration of the cornea consequent on neglected purulent ophthalmia.

It will be seen, from the following brief quotation, that the preceding treatment was based on a knowledge of a cause of the dimness of vision it was meant to relieve:—

"The dimness of vision cannot depend on the mere want of transparency in the vitreous humour," in fact, "the retina is compressed by an increase of its quantity." (a)

Now, the effect of puncturing the sclerotics, once, twice, or many times if required, in Glaucoma, as practised by me and recommended by me in my writings and lectures for the last twenty years, is so manifestly useful, that I submit it has a claim to attention, it has never, as would appear from Mr. Hulke's letter, as yet received.

Let me now state the advantages of the method of relief by puncture of the sclerotics.

(a) A Treatise on the Diseases of the Eye. London: 1835. Article "Glaucoma"—Vol. ii. page 19—Ibid. 14.

1. The tension of the globe is relieved and vision thereby improved.
2. A new and clear secretion is formed in the place of a less transparent one.
3. A tendency is communicated to the re-establishment of the normal fulness of the eye-ball; or, in other words, the re-adjustment of the fluid contents of the globe is promoted.

## DEATH FROM FIBRINOUS CONCRETION IN THE RIGHT SIDE OF THE HEART.

By CHARLES HOUSLEY,

Late principal Medical officer 2nd Division of the Army  
Works Corps, Crimea.

AMONG the numerous interesting subjects originated and discussed in Dr. Richardson's work on the "Coagulation of the Blood," a work which is now exciting so much attention in the Medical world, there is no question which to my mind so intimately concerns the practitioner of medicine as the one discussed in the fourth chapter of the appendix, under the title "Deposition of Fibrine in the Heart during Life." In this chapter the author, taking experiment and physiological fact as the basis, delineates and explains certain symptoms and pathological conditions, which every practitioner observant of the course and termination of acute inflammatory disorders, will at once recognise when the facts are laid out before him.

A case which has lately occurred under my own care offers from first to last so perfect a representation from nature of the description given by Dr. Richardson of a class of cases in the chapter of his work referred to above, that I make no apology for asking permission to publish it in your Journal.

On Sunday, April 4, at 8:45 a.m., I was called to see a child two years old. The history as given to me was very brief.—The patient was a little heavy the previous day and by her friends presumed to be sickening for measles, but the symptoms were so slight that they attracted scarcely any attention. She had previously enjoyed excellent health, and was a very fat, well-formed child. She had suffered from no cough, no difficulty of breathing, no fever. On the morning of the 4th, but shortly before sending for me, the child was found by its nurse on entering its bedroom suffering from intense dyspnoea, partial unconsciousness, great pallor and restlessness. When I arrived I found a continuance of these symptoms, and to my mind symptoms of death were clearly depicted on the countenance; the breathing was hurried, numbering sixty respirations per minute, the respiratory movements were mainly diaphragmatic, the body was universally deadly pale and waxy-looking; the radial pulse was feeble, relaxed, quick; the face was cold, features pinched; all of the nose in action; pupils dilated: there was but little consciousness, although when a mustard plaster was applied some manifestation of pain was evinced. Over the whole of the chest the respiratory sounds were loud, and posteriorly there was marked crepitation, but there was no cough at any period of the case. The sounds of the heart were obscure. The treatment adopted was very simple, consisting of the use of the warm bath, and the application of mustard plasters over the whole front and back, and subsequently the enveloping of the chest in warm wet flannel. From the fact of the pneumonic symptoms half a grain of calomel and half a grain of tartarized antimony were ordered to be given every four hours, and a gentle aperient, and nutriment was endeavoured to be supplied, but with little effect; but as might be expected from the symptoms, treatment proved of no avail, the little patient gradually sank, and died fourteen hours after my first visit.

From the suddenness of the symptoms and their peculiar character, this case possesses much interest. What was the diagnosis? There certainly were indications of pneumonia, but, to my experience, pneumonia simply in no way accounted for the whole, inasmuch as the general symptoms were not those of pneumonia, nor does the disease, in its uncomplicated form, take so marked or rapidly fatal a termination. The only diagnosis that offered itself was that the case was an example of those which Dr. Richardson has observed and described, where during inflammatory disorders a concretion is laid down on the right side of the heart. The symptoms

were, in fact, identical with those which he has described in pages 424, 425, and 426, of his work. I therefore set the case down as one which, if his observations were correct, should yield on post-mortem examination evidence of fibrinous deposition. A post-mortem was made forty-six hours after the death. The body was not very rigid. On opening the chest the lungs were found inflated, and superiorly of extraordinary whiteness. Emphysematous beads studded this surface. Beneath the lungs were dark and intensely congested, and the right lung was much solidified over a small surface. There was no effusion into the pleural cavities, nor signs of pleuritic inflammation. The large veins above and below the heart were filled with firmly-coagulated blood; the right auricle was much distended, and on laying it open was found to be completely filled with a fibrinous cast, exquisitely modelled to the cavity, and having impressed on it the irregularities of the muscular wall. The concretion was perfectly white, and on the right side of the auricle for the space of an inch it adhered so firmly to the muscular structure, that it could only be removed by forcible separation. From this clot there descended a cord of the same structure, of about the size of a goose-quill. This cord, entering the right ventricle, made a half-turn on itself, and ascending through the infundibulum, in the direction of the blood-current, extended into the pulmonary artery. As it crossed the semilunar valves it presented three concave surfaces, models, in fact, of the valves; there was no other blood in the right ventricle, but the endocardial surface was sheeted with a thin layer of plastic matter, like the concretion itself. I found also on examination that the concretion was laminated. On opening the left side of the heart the left auricle was found full of coagulated blood, but this blood was dark, and presented not the slightest trace of fibrinous separation; there was also a little dark, loosely-coagulated blood in the left ventricle. The other organs were normal.

After careful consideration of the facts of this case, including both symptoms and morbid anatomy, I have no alternative but to accept that the fibrinous concretion was laid down in the heart during life, and that it was the main cause of the peculiar symptoms and the immediate cause of the sudden death. Whether the lung disease was the forerunner or the sequence I am unable to decide; but that the peculiarities met with in the lungs are compatible as the sequence of obstruction to the pulmonary circuit is, I think, not improbable. Any way, the symptoms from the first were referable to obstruction of the circulation. They were symptoms resembling hæmorrhage; in fact, in some particulars, they were uncomplicated with any appearance of asphyxia, and after death there was found a sufficiency of unaffected lung structure to exclude the idea that death was due to deficient respiration. That the concretion was formed during life is demonstrated; it filled the auricle, so that it could not be said to be formed of blood left in the auricle after death; it bore the imprint of the muscular irregularities of the auricle, indicating a muscular pressure, during auricular contraction; it adhered firmly to the muscular wall, proving an interlacement of its fibres with the muscular structure, and it was laid down in layers; the prolongation from it took the sweep of the circulation, and even turned on itself, to make an acute angle upwards towards the pulmonary artery. The prolongation itself was modelled by the impress of the semilunar valves.

But there is one final demonstration which I see Dr. Richardson has not observed in his cases, and which admirably shows that in this case the clot was formed before death. While the right auricle was filled with a pure fibrinous deposit, the left was filled with an ordinary red blood clot, having no fibrinous separation whatever. Now it is obvious that when the heart in this instance ceased to beat, if the clot on the right side had been separated after death, the clot on the left side ought to have undergone the same modification.

As some of your readers may not have perused Dr. Richardson's experimental and pathological researches on the subject now in hand, I shall conclude this paper with a *résumé* of his views in relation to such cases as the one described above.

He points out that there are conditions of blood in which either from absolute or relative excess of fibrine, the fibrinous constituent is deposited in the heart: to use his own expression, is "churned out." He shows that these depositions may

be artificially produced in inferior animals, and that if an animal is rapidly narcotized after the symptoms of concretion are manifested and the chest laid open, the concretion may be found in the heart, while yet that organ is pulsating. (Essay, Experiment II. page 74.) He describes the difference between a concretion formed before and after death, by showing that the physical conformation of one formed before death invariably gives some indication that it could only be formed from blood in motion. Connecting these concretions with diseased conditions, he refers to them with special regard to the cases such as I have described. At page 424 he thus remarks: "All symptoms of acute inflammatory disease are attended with some risk of fibrinous deposition. Taking the majority of such cases, the risk certainly is small; but it is present in each case, and what renders the risk more serious is, that such risk or tendency to deposition cannot be measured by the local indications of inflammatory mischief in any given case, nor yet by the general symptoms which accompany the local. The symptoms of concretion may supervene in the mildest as in the severest cases. They may creep on insidiously; they may take effect in a sudden and unexpected outbreak."

On the diagnosis of these cases, where the obstruction occurs on the right side of the heart, he writes as follows:—"The symptoms are characterised primarily by a peculiar and distressing dyspnoea. This occurs, not because the respiration is checked, for the respiratory murmur may be audible enough, but because the current of blood to the lungs is in part cut off. As an addendum, emphysema of the lungs, especially in children, results; and the physical signs of this lesion are often a valuable corroboration of the presence of concretion on the right side. The left side of the heart being imperfectly supplied with blood, the arterial circulation is weakened, the pulse is small and intermittent, the surface of the body is cold and generally white as marble; but, as there is stagnation of blood in the venous circuit, the more vascular parts, as the lips and centre of the cheeks, are often of a leaden hue. There is general muscular prostration; and, as the brain is not supplied normally with blood, the muscles are not under the control of the will, but are in a continued restless motion. The mind loses its power, the acts of excretion are performed involuntarily, and death sets in, the gasping respiration outliving the paralysed and obstructed heart."

The pathological conditions noticed by the same author refer to the construction of the concretion, and to the appearances of other organs:—"Whenever a large fibrinous concretion blocks up some important part of the circulation for any considerable period antecedent to death, it gives rise invariably to certain pathological changes in neighbouring structures;" among which, when the concretion is on the right side, and the case occurs during the acute inflammatory diseases of young children, a "blanched and emphysematous" condition of the lungs is noticed as the most prominent sign. I need scarcely repeat that the case I have given agrees in every essential particular with the above description; however, I will observe that, while I have many times before met with cases the *fac-simile* of the one the history of which has now been given, I have never before understood so clearly the cause and meaning of death.

#### UNIVERSITY COLLEGE HOSPITAL.

#### PROGRESSIVE MUSCULAR ATROPHY OF THE MUSCLES OF BOTH ARMS.

(Under the care of Dr. HARE.)

[Reported by Mr. FREDERICK B. WHITE.]

PROGRESSIVE muscular atrophy has of recent years become a tolerably well-known form of disease, though well-marked cases of it are amongst the rarities of Medical practice. We are glad, therefore, to be able to record a well-marked form of the disease, which exhibits, as is so frequently the case when affecting a limb, a decided tendency to symmetry. The

patient, although spare in the frame generally, has not, except in the limbs affected, lost flesh to any notable amount, and the lower extremities are of natural size. Her family were phthisical, her father and mother having died of consumption; but this patient is free from all such disease.

She is a woman of 48 years of age, and when she first came under Dr. Hare's treatment, on the 20th July, 1857, the atrophy of both arms was extreme, the right being rather the worse of the two. The biceps and forearms were so small and flabby that they could scarcely be felt, except on contraction, and then only slightly. The muscles of the forearm were also much atrophied, the pronator radii teres being perhaps the one which was least so; the ball of each thumb was likewise much flattened. She had but little use of her arms, as might be expected; she could not flex the right forearm without pronating it, owing doubtless to the greater amount of affection of the various supinators, as compared with the biceps and pronator radii teres. The left arm she could just manage to flex without pronation, and she could pronate and supinate both arms when they were extended. Dr. Hare mentioned at the time that he had seen two or three other instances of this rare form of disease, and that they were cases in which treatment had hitherto been of but little avail. Dr. Hare also referred to some cases mentioned by Aran, and published in the "Archives G n ral."

The patient's general health not being at all in a good state, she was put first on a tonic mixture containing steel, and a vegetable bitter, the arms were also galvanized twice a week, and she had a liniment of turpentine and aconite to apply twice a-day. This was continued till the 24th of August, when she commenced taking five grains of potass. iodid. three times daily.

Not deriving much benefit from this treatment, Dr. Hare on October 5th prescribed for her a mixture containing one-twentieth of a grain of strychnine, to be taken three times a-day. On the 12th this was increased to one-sixteenth of a grain.

This plan was persisted in, the dose being gradually increased without any ill effects till the 22nd of February, 1858, when she first experienced slight twitchings in the limbs, the dose having been increased to one-eighth of a grain.

She had at this time taken 32 grains of strychnia in four months and a half.

This mixture was then discontinued, and she has since been again taking steel, with ol. morrh  , and using the liniment at first ordered.

She has during this time certainly improved, although but slowly; she can accomplish all her household work without assistance, but she cannot yet use her needle much.

It is particularly to be noticed that this case did not depend on prior paralysis, as there was no loss of power before atrophy came on; nor has there been, nor is there any an sthesia.

#### PSORIASIS OF THE MATRICES OF THE NAILS.

(Under the care of Dr. HARE.)

[Reported by Mr. FREDERICK B. WHITE.]

It is curious how cases, in themselves rather rare, occur sometimes in clusters. Almost every one can call to mind instances of this kind. A rather unusual case occurred at University College Hospital a short time since, in which psoriasis affected the matrices of the nails only, and in which the diagnosis of course, rested solely on a careful examination of the deposit under the nails.

A case connecting in an interesting manner the example just referred to, with the more ordinary form of the disease, is at present under the care of Dr. Hare, at the above hospital.

The patient is a woman, aged 28, and on admission she presented but slight traces of the disease at any other part excepting the nails, the few spots she had being on the arm and forehead. She was, however, in the hospital twenty years ago, under treatment for psoriasis, which affected the whole body. She left much relieved after having been for 13 months an in-patient, but has been liable to slight recurrences of the disease ever since.

Her attention was first drawn to the nails of the great toe (which are the only ones diseased on the feet), on account of the pain caused by any exertion. These seem to have been more severely affected than those of the hand, the disease

probably aggravated by the pressure to which they were subjected in walking.

The scales were deposited in such abundance, as (unlike in the former case) to entirely separate the connexion between the nails and their matrices, so that they have been cast off and renewed three times.

On the right hand the matrix of the thumb, and on the left those of the middle and ring fingers are also similarly, though not so severely, affected. Thus there was also the usual tendency to symmetry, which is so generally observed in psoriasis, manifested in the toes, though not so clearly in the fingers. It may be remembered that in the former example, the symmetry was very distinct.

This being the condition of the patient, Dr. Hare put him upon the plan of treatment which he has found to answer very well in cases of psoriasis, viz. liq. potassæ in half-drachm doses, and liq. arsenicalis in five-minim doses, three times daily, in water. She is, under this treatment, rapidly improving, the disease having almost entirely disappeared.

## THE DREADNOUGHT HOSPITAL SHIP.

### CASES ILLUSTRATIVE OF CERTAIN POINTS IN THE DIAGNOSIS, ETC., OF FACIAL PARALYSIS.

(Under the care of Dr. WARD.)

[Communicated by F. M. CORNER, Esq.]

*Case 1.—Fall on the Head.—Paralysis of the fifth pair and of the left facial nerve.—Sloughing of both corneæ a month after the accident.—Slow recovery of sensation, etc.*

The first of the following cases is an instance of complete anæsthesia of the fifth pair, resulting from an injury to the base of the skull, caused by a fall into the hold of a vessel. The first symptom noticed (the man being insensible) was an opacity of both corneæ, followed by sloughing and collapse of the globes, and on testing for sensation in the course of the nerves, it was found entirely wanting. The surface of the eyeballs, the interior of the nostrils, mouth and ears, and the integument covering the face, were all dead to impressions. The dulness in the corneæ commenced about three or four weeks after the accident. He was also observed to have the face drawn to the right side, the left facial being involved in the injury; and the reflex power of the fauces was deficient, if not wanting, allowing the finger to be swept round neighbouring parts, and even seated on the epiglottis without inducing spasms. The motor power of the fifth was unaffected. Two months after the accident he complained of pains of a stinging character about the face, and pointed to three places corresponding to the points of exit of the divisions of the fifth, viz. the supra and infra orbital, and the mental, where his suffering was most felt. The integument of the face was also preternaturally sensitive. He left the Hospital three months after his admission, and I saw him a few days ago, having been out five weeks, and then found that he had sensation in the previously anæsthetic parts, though not so perfect as before the injury.

From the history of this case there was no difficulty in fixing on the base of the brain as the seat of the lesion, and from the result, we may infer, that either pressure or inflammation, which gradually passed off, was the cause. The treatment was very simple, and with the exception of leeches once applied, might be said to consist of rest, an occasional purge and blister, liquid diet, gradually returning to meat through light puddings, fish, eggs, etc.

*Case 2.—Albuminuria and otorrhœa.—Paralysis of both sides of the face with deafness.—Dryness of mouth, and paralysis of soft palate. No benefit from treatment.*

The man, aged 30, was deaf when admitted, and could not either read or write, rendering it difficult to obtain a clear history. He stated that he had had a discharge from both ears (coming on first during an attack of scarlet fever) as long ago as he could recollect; that three and a-half years ago he had a sore on the glans penis, where now exists a cicatrix, and that he has never had sore throat or eruption on the body since; that he has never had rheumatism, but that in July last he was in this Hospital with swelling of the legs, and on reference I find it was for albuminuria, which still exists; that eight or nine months ago the discharge from the

left ear ceased, and was followed by gradual imperfection of hearing on that side, which went on to complete deafness, and that the opposite ear became similarly affected about the same time; that five or six months after the commencement of the deafness he got paralysis of the left half of the face, and in a few weeks the same on the opposite side. On admission to the Medical deck, under Dr. Ward, he presented the following symptoms:—He seemed much out of health; had a pale and pasty appearance, and very feeble circulation; his countenance was particularly striking—a smooth, relaxed, and solemn expression, the eyeballs were much exposed, and a superabundance of secretion standing in the lower lids, which were not closely adapted to the surface of the globes; the nostrils were collapsed; the lips apart to nearly an inch; and in speaking he had to use his finger to the lower one to pronounce the labials. The face was elongated apparently from drooping of the integument. His mental faculties were intact, and he gathered from the motion of the lips pretty correctly what was said to him. On looking into the right ear, a polypus was detected, which was removed without change to his symptoms. The left membrana tympani was deficient in a small portion, and on adapting a piece of wool to the apertures no alteration in the hearing resulted. His chief complaint was of dryness in the mouth, which awoke him nightly, and required frequent moistening. He felt the same to a less unpleasant degree in the nostrils, and occasionally he suffered hemicrania of the right side. On examining his throat for paralysis of the soft palate, said to be diagnostic of lesion of the facial in the temporal bone from injury to the petrosal nerve, the uvula and pillars of the fauces were seen to be relaxed, reducing the size of the isthmus, destroying the arches of the palate, and approximating the pillars of opposite sides (which were nearly parallel). Another (said to be) diagnostic symptom, is the dryness of the mouth, supposed to depend on injury to the chorda tympani in the internal ear, causing paralysis of Wharton's duct, and arrest of the passage of saliva from the sub-maxillary glands. It is also, as in this case, partly the result of inability to close the lips, the constant passage of air to and fro causing it. On evertting the lips, the fluid in the mouth seemed more like gum water than saliva, and after he had taken mercury to slight pytalism, he at once expressed himself relieved of the unpleasant dryness, which returned on the mineral being stopped. Partial paralysis of the sense of taste on the half of the tongue corresponding to the affected side, also said to occur and to be symptomatic of the disease in the bone, was tested for, but could not be satisfactorily made out on account of the difficulty of explaining what was wanted. Galvanism produced no effect on the paralysed muscles. He was placed on good diet, with wine, and porter; was prescribed iodide of potassium with citrate of iron, and counter-irritation behind the ears; then small doses of mercury to slightly touching the mouth, all with no good result. He left the Hospital, as expected, unrelieved.

*Case 3.—Paralysis of the right facial, with partial loss of hearing.—History of syphilis.*

R. W., aged 24, contracted syphilis in Hongkong, in Nov. 1866, and dosed himself with mercury to profuse pytalism. He then went into the Hospital there on account of ulceration of the prepuce, and after being in for ten days, was seized with severe pains in the head and right ear, accompanied by vertigo, heaviness, and fever. The symptoms were subdued by leeching, but recurred several times, the same treatment being carried out. Shortly after the onset of this attack he noticed his hearing on the right side to be impaired, and about the same time the paralysis supervened. He states that the pain in the ear was most violent, and kept him from sleep several days and nights. Altogether he was in the Hospital nine weeks, and left without relief to the paralysis. The Surgeon, he says, viewed his illness as "sun-stroke." He now went to Foochow, and was there advised by a Medical man to undergo treatment for his face. He did, and was again salivated, and while under the influence of the mineral, he had a return of the pains in the head and ear, and swelling on different parts of the scalp; also some discharge from the ear. He again went into Hospital, and remained an inmate sixty-eight days, leaving it free from pain, but unrelieved in his facial affection. He has occasionally felt pain in the ear and head during his passage home. On March 2 he was admitted

into the Dreadnought under Dr. Ward, with the following symptoms. Paralysis of the right half of the face involving all the muscles supplied by the seventh; partial deafness of the right ear, not hearing the tick of a watch, or when spoken to in an under tone. The uvula and soft palate were unaffected, the former being slanted a little to the left. Had not recognised any dryness in the mouth, and on testing the gustatory no perceptible difference could be noted between opposite sides. He has had since his admission several acute nodes on the forehead, and behind the ears, and acute enlargement of the cervical glands, and once or twice a stabbing pain in the right temple, producing a shock, and slight convulsion of the right half of the body. Galvanism produced no effect on the paralysed muscles. An examination of the right ear showed a white, pearly membrana tympani, the colour and brightness being more marked than on the opposite side. He has been taking the iodide of potassium with marked relief to the peristitis, and aural pain, but with no change to the paralysis.

### HOSPITAL NOTES.

#### SEVERE INJURY TO THE BRAIN, WITH VERY SLIGHT IMMEDIATE SYMPTOMS.

The following case is reported to us by Dr. Eubulus Williams, the House-Surgeon of the Dundee Royal Infirmary. A man, aged 24, was admitted with a compound fracture of the skull, which extended on the left side from the orbit to the upper part of the frontal bone. The dura mater was torn, and the anterior lobe of the brain injured. Soon after his admission, "about two ounces" of cerebral matter escaped. Several small portions of loose bone were removed. The injury had been caused by the breaking of a crane chain, one end of which had recoiled with great violence and struck the man's head. The man was perfectly sensible when admitted, and remained so afterwards. During the next few days his pulse was slow, ranging from 54 to 58. No untoward symptoms whatever occurred until six weeks after the accident. The man often complained of being kept to bed, and alleged that he felt as well as ever he did in his life. Three days before death he had headache, and on the following one had become comatose. Active treatment by calomel, etc., was adopted, but death in deep coma followed. No autopsy could be obtained. The case is of much interest, as showing the importance of exercising the utmost caution both in prognosis and treatment for long periods after cerebral injuries; it also shows how slight may sometimes be the immediate effects of a very severe accident. The want of post-mortem evidence is much to be regretted; but there can be little doubt but that cerebral abscess was the cause of death.

### THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

#### STATISTICAL REPORT OF THE PRINCIPAL OPERATIONS PERFORMED DURING THE YEAR 1857.

(Continued from p. 402.)

THE subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

#### LITHOTOMY.

Case 1.—The Leeds: Mr. Hey.—A thin, delicate man, aged 22, the subject of stone for eight years. For a week before the operation the stone had been impacted in the mem-

branous urethra. An incision was made opening only the membranous tract, and the impacted stone was easily removed. A second calculus, which was free in the bladder, was removed without further incision. Recovery. Case 2.—The Bradford: Mr. Parkinson.—A boy, aged 6. The stone was of small size, and had become impacted in the membranous urethra. Recovery. Case 3.—The York: Mr. Husband.—A feeble man, aged 73. Usual operation. Recovery. Case 4.—The Derby: Mr. Gisborne.—A boy, aged 6. Removal of a soft, phosphatic calculus by the usual operation. Recovery. Case 5.—The Cheltenham: Dr. Wright.—A boy, aged 10. Usual operation. Recovery. Case 6.—The Bristol General: Mr. Coe.—A boy, aged 5. Removal of a phosphatic stone. Recovery. Case 7.—The Bradford: Mr. Meade.—A boy, aged 11, in fair health. Stone, mulberry, and of considerable size. Recovery. Case 8.—The Cheltenham: Dr. Wright.—A boy, aged 10, for some years the subject of stone. Usual operation. Recovery. Case 9.—The Sheffield: Mr. Gregory.—A boy, aged 11. Removal of medium-sized mulberry calculus. Recovery. Case 10.—The Leeds: Mr. Teale.—A puny boy, aged 4, for three years the subject of stone. Usual operation. Recovery. Case 11.—The Leeds: Mr. Teale.—A healthy man, aged 20, who had been operated on for stone when four years old, and had remained without symptoms until within fourteen months. Usual operation. Recovery. Case 12.—The Glasgow.—A man, aged 26. Usual operation. Recovery. Case 13.—The Glasgow.—A boy, aged 6. Usual operation. Recovery. Case 14.—The Leicester: Mr. Macaulay.—A boy, aged 5, in good health. Calculus small. Recovery. Case 15.—The Leicester: Mr. Paget.—A boy, aged 12, in good health, who had been subjected to lithotomy eight years previously. Symptoms of stone of six weeks' duration. Usual operation. Recovered. Case 16.—The Brighton: Mr. Furner.—A boy, aged 8, in poor health. Usual operation. Recovery. Case 17.—The Queen's, Birmingham.—A delicate boy, aged 11, who had been operated on for stone at the age of 7. The symptoms had recurred within three months of the operation. At the second operation the stone was impacted firmly in the bulbous tract. Recovery. Case 18.—The Dorset: Mr. Curme.—A boy, aged 4. Usual operation. Recovery. Case 19.—The Brighton: Mr. Blaker.—A man, aged 38, in feeble health. A large stone had been removed a year previously, but he had never been free from symptoms. A stone weighing three drachms, and composed of mixed phosphates, was removed. Recovered. Case 20.—Addenbrooke's, Cambridge: Mr. Humphry.—A healthy man, aged 62, the subject of enlarged prostate. The usual operation was performed, and two moderate-sized calculi were removed. He did well afterwards, but at the time of report the wound was not healed. Case 21.—Addenbrooke's, Cambridge.—A healthy man, aged 65. Removal of a small lithic acid stone. Doing well. Case 22.—The North Stafford: Mr. Garner.—A young boy, for six months the subject of stone. Usual operation. Recovery. Case 23.—The North Staffordshire: Mr. Garner.—A boy, aged 4. Recovery. Case 24.—The Cheltenham: Mr. Eves.—A man, aged 65. Usual operation. Recovery. Case 25.—The Cheltenham: Mr. Eves.—A delicate boy, aged 12. The subject of stone for six years. Recovery. Case 26.—The North Stafford: Mr. Garner.—A healthy boy, aged 3. Usual operation. Recovered. Case 27.—The Glasgow.—A boy, aged 11. Usual operation. Recovery. Case 28.—The Glasgow.—A boy, aged 3. Operation with rectangular staff. Recovery. Case 29.—The Glasgow.—A man, aged 34. Operation with rectangular staff. Recovery. Case 30.—The Glasgow.—A boy, aged 4. Usual operation. Recovery. Case 31.—The Leicester: Mr. Paget.—A man, aged 63, in good health, for two years the subject of stone in the bladder. Perineal lithotomy. Removal of a stone weighing nearly four drachms. On the second day retention of urine made the use of the catheter necessary, and it was with much difficulty introduced. Some ecchymosis of the scrotum followed the operation. The man recovered well. Case 32.—The Hull: Dr. Lunn.—A man, aged 25. The usual operation was performed, and a large quadrilateral stone weighing sixteen drachms was removed. Recovery. Case 33.—The North Staffordshire: Mr. Garner.—A healthy man, aged 64. Seven small calculi were removed by the usual operation. Recovery. Case 34.—Addenbrooke's: Mr. Lessourgen.—A child, aged 3, in good health. Usual operation. Small stone. Recovery. Case 35.—Addenbrooke's: Mr.

Humphry.—A healthy man, aged 55. Usual operation. Large stone. Recovered. *Case 36.*—Addenbrooke's: Mr. Humphry.—A delicate child, aged 2, who had had symptoms of stone from birth. Usual operation. Small lithic acid stone. Recovered. *Case 37.*—Addenbrooke's: Mr. Humphry.—A healthy man, aged 26, for four years the subject of stone. Usual operation. Recovery. *Case 38.*—Addenbrooke's: Mr. Humphry.—A healthy man, aged 65. Three small calculi were removed. Recovered. *Case 39.*—The Liverpool Southern: Mr. Minshall.—A boy, aged 8. Usual operation. Small stone. Recovery. *Case 40.*—The Liverpool Southern: Dr. Nottingham.—A boy, aged 6. Usual operation. Stone small. Recovered. *Case 41.*—The Brighton: Mr. Furner.—A feeble man, aged 64, for two years the subject of stone. Usual operation. Death from phthisis ten weeks afterwards. *Case 42.*—The Leeds: Mr. Teale.—A feeble man, aged 22, for five years the known subject of stone. The calculus weighed four ounces and a half. Profuse hæmorrhage occurred in the evening of the day of the operation, and was with difficulty arrested by the use of the actual cautery, and by plugging. He never rallied well, but died on the eighth day. The autopsy showed alight peritonitis and suppuration in the cellular tissue about the rectum. The kidneys and bladder were much diseased. *Case 43.*—The York: Mr. Husband.—A feeble, scrofulous boy, aged 5. Removal of a mulberry calculus the size of a large hazel nut. Death from a low form of peritonitis on the fifth day. The autopsy showed the bladder much thickened and diseased. *Case 44.*—The Glasgow.—A boy, aged 3. The bi-lateral operation was performed, and a lithic acid stone, weighing 244 grains, was removed. Death from collapse on the same evening. Nothing was found at the autopsy to account for the sudden death. The peritoneum had not been injured. *Case 45.*—The North Stafford.—A stout man, aged 48. A large lithic acid stone, weighing two ounces and a half, was with considerable difficulty removed. Death on the second day. At the autopsy the parts about the wound were found in an almost gangrenous condition. There was also commencing gangrene of the under surface of the thigh.

#### LITHOTRITY.

*Case 1.*—The North Staffordshire: Mr. Garner.—This patient is still under care. The first crushing produced severe vesicle irritation. *Case 2.*—The Brighton: Mr. Turner.—A man, aged 57, in good health. Five crushings were practised, and the collected fragments weighed more than a drachm and a half. Recovered. *Case 3.*—The Glasgow.—A man, aged 23, for many years the subject of stone. Recovery. *Case 4.*—The Glasgow.—A man, aged 61. Death from collapse the day after the first crushing. At the autopsy nothing was found to account for the fatal event. *Case 5.*—The Leicester: Mr. Benfield.—A healthy labourer, aged 59. The stone was repeatedly crushed a single sitting. Many fragments were afterwards passed, and no ill-symptoms ensued. When discharged he was considered quite well. *Case 6.*—The Bradford: Mr. Meade.—A strong, healthy man, aged 56. Symptoms of stone of a year's duration. Two crushings with a few days' interval were practised, and fragments weighing 96 grains were passed. Recovery. *Case 7.*—The West Norfolk: Dr. Cotton.—A man, aged 56, who had been discharged from the Hospital five months before, in belief that he had been cured by lithotripsy. Three crushings were performed for the removal of second stone, and three rachms of a phosphatic calculus came away. He was discharged after one month's treatment, seemingly quite well.

#### LITHRECTASY, ETC., IN WOMEN.

*Case 1.*—The Glasgow.—A woman, aged 60, for a year and half the subject of stone. Removal. Recovery. *Case 2.*—Addenbrooke's: Mr. Humphry.—A healthy girl, aged 6, for two years the subject of stone. On Jan. 3rd, after dilatation of the urethra by bougies the lithotrite was used, and the stone crushed. Several fragments passed. On the 14th the crushing was repeated. On the 20th no remains of the stone could be found. Recovered. *Case 3.*—The Brighton: Mr. Furner.—A woman, aged 34, for twenty-two years the subject of stone. The stone weighed fifteen drachms. Death from the effects of the operation.

## Medical Times & Gazette.

SATURDAY, APRIL 24.

### ALLEGED DEATH FROM ARSENICAL VAPOURS— THE FIRE IN BLOOMSBURY.

At the adjourned inquiry into the deaths of fifteen persons who perished in the fire at Bloomsbury, some Medical evidence was given which calls for a passing notice. Most persons had made up their minds that the deaths were sufficiently accounted for by suffocation; and some surprise was excited by the issuing of an order from the Coroner that fourteen of the bodies should undergo a regular medical examination. It appears from the report of the proceedings last week that this had been carried out to a very minute extent, and that the stomachs of five had been analysed by Mr. Rodgers and Mr. Girdwood, with a view to the detection of poison. We learn from the evidence that the bodies were in a healthy and natural state: the reposing attitudes in which some were found were ascribed to a state of comparative insensibility at the time of death. "There was a peculiar lightness in the colour of the blood; it was of a bright red, which would not have been the case had suffocation been the cause of death. There was one exception, and in this case (William Hedger) death was caused by suffocation." Such is the substance of the evidence of Mr. Bennett, who made the examination.

Mr. Rodgers stated that he was present at the examination of eight of the bodies, and took for analysis parts of five of them, viz. the blood, lungs, stomach, and some of the air-passages. "There was a redness of the muscles and the blood, whereby he apprehended there must have been an inhalation into the system of some unnatural and unusual fluid." He, therefore, examined the premises, and found that some minerals containing arsenic, had been consumed in a room adjoining the immediate locality of the fire. He believed the cause of death to be "the inhalation of poisonous (arsenical) vapours ascending from these burning minerals, and which by producing immediate prostration and utter inability on the part of the sufferers to remove, allowed the effects of smoke from the burning timbers to accomplish their deaths more speedily and effectually." "If they had died from suffocation, the blood would have been of a dark colour." He knew "of no exception to this appearance in cases of suffocation." Subjects when preserved by arsenic evince this remarkable evidence of colour. Solution of arsenic injected into the vein will redden all the tissues. "The chief instrument of death in four out of the five bodies analysed by him, was the poison of arsenic." The report then continues—"A jurymen inquired of Mr. Rodgers, if death would have been produced without the assistant agency of smoke arising from the burning building."

"Not so quickly," he replied. "The difference of action between common smoke and arsenious acid, consists in the fact, that when the latter is inhaled, prostration immediately

succeeds; but vapours from burning wood which contain carbonic acid, and in which no person could live, acting on a system prostrated by poisonous gas, would speedily cause death." Hence it would follow, that the arsenical vapours entered the bodies before the products of combustion, although it is not apparent how the arsenic could have been volatilized until after a considerable burning of the premises. A corrected statement of a portion of Mr. Rodgers's evidence has been subsequently published. He says, "In the process of analysis, I found no narcotic poison, but *distinct traces* of arsenic in four of the bodies which I had examined. I had a large quantity of William Hedger's blood (the person who was stated to have died from suffocation), and in that blood there was *less arsenic* than in any of the others. I found unequivocal and sufficient evidence to satisfy my mind that there was arsenic."

Mr. Girdwood supported Mr. Rodgers's evidence, adding,—that "the vapours of arsenic produced coma, and prevented the sufferers from making an attempt at escape." . . . "Arsenic when inhaled always acts as a narcotic poison. The air-passages had bright red spots, showing the effect of an irritant poison."

The unlucky mineralogist who owned the arsenical minerals "was feelingly told by the Coroner," that "materials on his premises, owing to defect of structure, had been more concerned in producing the death of those fifteen human beings than any other agent." And the lessee of the premises was recommended to attend the inquest on Monday next, the 26th, with a legal adviser.

It has thus been placed before the Coroner and jury that these unfortunate people have perished from the effects of arsenical vapours, and not from the ordinary vapours or gases which are evolved in a burning house. It is true the medical gentlemen qualify their opinions to a slight extent by saying that the deceased were prostrated by the arsenic, and thus were easily killed by the smoke; but in law that which accelerates, causes. The real question, as a matter of science and law, therefore, is: "Did arsenical vapours tend in any way to cause the deaths of these persons; or, were not the deaths caused by the gases of burning wood?" The mineralogist and his landlord are at present in some peril, unjustly as we think; for there is not a particle of evidence to support the extraordinary conclusions at which the chemical witnesses have arrived.

We admit that there were arsenical minerals near the premises, and that the combustion of these would diffuse vapours of arsenious acid, which might mix with the burnt and unburnt air, and be breathed by the inmates of the house; but what we desire to know is—on what grounds death is substantially referred to these vapours? It cannot be merely because "*distinct traces*" of arsenic were found in the bodies, since arsenic is stated to have been found in the blood of one who is admitted to have died of suffocation. The relative amount of arsenic can have nothing to do with this question, since it does not appear that more than "*traces*" were found in any of the bodies. The only appearance on which the witnesses rely is the *light red colour* of the blood and muscles. But where did they learn that the breathing of arsenious acid in vapour mixed with air produced this colour in the blood and muscles? So far as we can ascertain, there is not a fact on record which justifies such an inference. The suggestion that a solution of arsenic injected into the veins will redden all the tissues is quite irrelevant, because there was no solution of arsenic injected into these bodies; and the bodies could not have been impregnated with arsenic in a few minutes by respiration, so that it should manifest its ordinary preservative properties on animal matter. The effect of arsenic on the blood is not to redden it: all authorities agree that it is darkened, and turned to a reddish brown, or black-

ish purple colour. (a) In one case referred to by the witnesses (William Hedger), there was arsenic in the blood; but the blood had a dark colour, and death was referred to suffocation.

But vapours of arsenious acid when breathed, are stated to produce *immediate* prostration and inability to move. According to Mr. Girdwood, arsenic, when inhaled (in vapour), *always* acts as a narcotic poison; and he immediately adds to this curious piece of evidence, the corrective statement—"the air-passages had bright-red spots, showing the effect of an irritant poison;" so that here we have, according to this witness, arsenic in vapour acting as a narcotic and as an irritant in the same body, when there is no reason to believe that the persons could have lived above two or three minutes! We ask for proof that arsenious acid thus breathed with air, acts as a narcotic, or prostrates a person in the manner alleged. At present it is a mere speculation. All that we know of arsenical vapours is adverse to the theory. In the Arsenic works in Cornwall, no such effects have been observed: (b) and animals both in that county and in South Wales, that have been exposed to these vapours, have suffered from the poison as an irritant operating slowly on the mucous membranes and joints. In one of the very few cases of poisoning by arsenical vapours in the human subject that have occurred in this country, death was caused by inflammation of the lungs, after some days, as the result of inhalation. (c) There was no narcotic effect, no sudden prostration, but the usual results of the irritant action of the poison on the mucous membranes.

Then we have the strange assertion that "common smoke" does not produce prostration and death "so quickly" as the arsenical vapours. This depends on what is intended by "common smoke." If it is meant to imply carbonic acid or carbonic oxide, or a large proportion of either of these products of combustion, we will venture to affirm that, in respiring such mixtures, the person will die before the arsenical fumes can affect him, either as an irritant or as a narcotic.

The arsenical theory, therefore, of death, or of the acceleration of death in these cases, is not supported by a single medical fact. The discovery in four of the bodies of such an imponderable quantity of arsenic as is implied by the expression "*distinct traces*," amounts to nothing. The deceased persons could not have received enough to kill or affect them in the short time during which they lived, and in this short time they could not have got rid of any portion which they had received by respiration. The death in the exceptional case, in which the blood was dark (containing *less arsenic*), might just as well have been referred to the arsenical vapours as the deaths of the others; and yet, because the blood was dark, and the arsenic in smaller quantity than "*distinct traces*," the witnesses drop the arsenical theory, and refer death to suffocation!

The whole of this evidence is, in our judgment, calculated to alarm the public unnecessarily, and to place in jeopardy the liberty of two persons who have had no concern in the deaths of these unfortunate individuals. Without any experience of the effects of arsenical vapours on human beings, and in ignorance of what is known concerning the effects, these witnesses take upon themselves to assign death to arsenic, because the blood did *not* present that appearance which they consider indispensable to all kinds of death from suffocation. On this point their knowledge appears to be as restricted, as on the effects of arsenious acid in vapour.

One of the products of incipient or imperfect combustion is oxide of carbon; and a well-known French physiologist, M.

(a) See Christison on Poisons. 4th ed. Pp. 348.

(b) Association Medical Journal, September 20, 1856, p. 909.

(c) This case occurred at Plymouth in October, 1852.

Bernard, has demonstrated by experiment (d) that this gas possesses the property of giving a red colour to the blood. In one case he found, where frequent and large respirations of the gas were made, that the red colour was retained for a period of fourteen days. In another experiment, in which fewer and smaller respirations of the gas were made, the red colour did not remain long after death. The blood became again dark.

The chief fact, therefore, upon which the witnesses based their opinions, is really no feature of poisoning by arsenic, either in vapour or in any other form; while it has been proved to be one of the appearances produced by a gas which might have been evolved during the partial burning of the interior of the premises. The only conclusion of which the facts admit in a medical point of view, is that death took place from suffocation by the gases of burning timber; yet from the strong opinions expressed at the inquiry, with all the imposing effects of science, it will not surprise us to find that the mineralogist and his landlord are committed on a charge of manslaughter.

### THE WEEK.

A knotty point has been recently raised in the Parisian law-courts. By a law passed in 1851 for the suppression of fraud in commerce, the sale of, or offering for sale, of an adulterated or damaged medicinal substance is punished by an imprisonment of from three to twelve months. The Paris Court has recently applied this law to the selling of leeches when gorged with blood, considering them as damaged medicinal substances. The lawyers disputed the fact of a leech being, in the proper sense of the term, a medicinal substance, which they said means a substance capable of being absorbed wholly or in part by the tissues of the economy; the leech is a mere instrument, practising an operation under the guidance of man. The Court of Cassation, however, when appealed to, taking the common sense view of the subject, declared that the leech, being employed as an external medicament in the art of healing, must be regarded, in respect to the deterioration of its powers when gorged, as a medicinal substance.

At the festival of University College Hospital, Lord John Russell alluded to a fact not generally known, but one well worthy of consideration. He said—"They were now about £4000 in debt, and would have been much more so, but for the unparalleled generosity of the Professors of the Medical School. These gentlemen were entitled to the fees paid by the students, and since the establishment of the Hospital they had relinquished them all, thus contributing no less a sum than £53,000 to its support." This is very noble and generous; but is it not time that gentlemen who have worked in this manner should now receive some reward for their services?

A copy of a petition from the Epidemiological Society presented to the House of Commons on the 16th inst., by Sir John Pakington, will be found in another column. The petitioners well observe that no measures can "less admit of postponement than those which would effect a saving of human life." Small-pox is becoming more and more epidemic in the country of Jenner. In the last quarterly return of the Registrar-General twenty-seven towns are reported in which small-pox was extensively prevalent. During the last quarter of 1857, one-seventh part of the whole mortality of Sheffield was from small-pox. During May, June, and July, 1857, considerably

more than one-third of the total mortality of the Cardiff-registration district was from small-pox. There were in that period 119 deaths from small-pox in that town and district. Surely this is a disgrace to us as a nation, and it behoves the Medical part of the community to show our rulers their duty. The great health question of the day must not be left under the Poor-law Board—a Board without a Medical adviser, ignorant of its duty, and therefore failing in its performance.

The appointment of Dr. Alfred Taylor to the examinership in Chemistry in the Medical Department of the University of London will tend to raise still higher the character of this body. It must be highly satisfactory to Dr. Taylor to have obtained the post after competition with two highly-qualified men; while these gentlemen will not consider it any disparagement that a Chemist who has earned by his works so high a reputation in all quarters of the world should have obtained the appointment.

A girl, 11 years of age, has been poisoned at Newcastle by worm-lozenges. She took four of them, and was profusely salivated. On analysis of some of these lozenges, one was found to contain five grains and another three grains of calomel. The verdict of the Coroner's jury was—"We are of opinion that Sarah Jane Harris came to her death on the 1st of March, 1858, by salivation, produced by taking four worm-lozenges, purchased at the shop of Henry Jenkins, confectioner, of Dean-street, Newcastle; and we are further satisfied by the evidence that there is great and dangerous irregularity in the mixing of the said lozenges." Yet these things are sanctioned by a Government stamp!

Mr. Sands Cox has brought an action for libel against the *Birmingham Daily Post*. A man was admitted with stone into the Queen's Hospital, under Mr. Cox. It was found that he was labouring under kidney disease, and determined, after careful consideration and consultation, that lithotomy would be useless, and would probably hasten the man's death. Mr. Gamgee gave a clinical lecture on the case, and a writer, calling himself a *layman*, commented on the treatment in a letter published in the *Daily Post*. It will be for a jury to determine whether those comments were fair or malicious. Whatever a jury may think, we think the Profession will support Mr. Cox in having the case tried. If Hospital Surgeons are to have their treatment of cases criticised by the newspapers, and are to be blamed for rashness if their operations are followed by death, and for cowardice or ignorance if they do not operate, no one would be likely to spend his time in charitable exertions in an hospital, with the sword of anonymous enemies hanging over his head.

It will be recollected that, in the early part of the present year, we drew attention to the case of Mr. Symes, of Bridgewater, who was subjected to a series of cruel persecutions at the hands of the local Board of Guardians, and who, after a one-sided investigation before a Poor-law Inspector, was directed to resign his appointment as one of the Medical officers of the Bridgewater Union. Against this decision of the Poor-law Board, Mr. Symes warmly protested; and after a long correspondence with the officials at Whitehall, it was at length resolved to allow Mr. Symes to bring forward any additional evidence he might be able to procure, before two of the Poor-law Inspectors sent down from London. The new investigation accordingly was opened at Bridgewater on the 30th ult., and it is not yet concluded. While the pro-

(d) *Leçons sur les Effets des substances Toxiques et Médicamenteuses*, par M. Claude Bernard. Paris, 1857, p. 192.

ceedings are still pending, we abstain from further comments on the case, but we cannot refrain from observing upon the very unwarrantable attempt made by the Local Board to prejudice Mr. Symes in the eyes of the Poor-law Board. It appears that the Bridgewater Guardians have drawn up a memorial to the Poor-law Board, disputing the necessity of the fresh inquiry, complaining of its expense, and urging the dismissal of Mr. Symes. We can only hope that the Poor-law Board will not be swayed by any such remarks, and that the inquiry will be completed in a spirit of justice and fairness. We are sure that Mr. Symes requires nothing but a fair and impartial hearing, and we trust that it will now be accorded to him.

"A deputation from the Medical Corporations of England, Scotland, and Ireland, had an interview with Mr. Walpole, Home Secretary, on Saturday, at the Home Office. The deputation consisted of Dr. Mayo, president; Dr. Hawkins, registrar; and Dr. Burrows, from the College of Physicians, London. Mr. Stanley, president; and Mr. Lawrence, from the College of Surgeons of England. Mr. Simoons, master; Mr. Tegar, chairman of the Court of Examiners, from the Society of Apothecaries. Dr. Alexander Wood, from the College of Physicians of Edinburgh. Dr. A. Wood, president of the College of Surgeons of Edinburgh. Dr. Watson, president, from the Faculty of Physicians and Surgeons of Glasgow. Dr. Neligan, Censor of the King and Queen's College of Physicians in Ireland. Dr. Williams, member of council, from the College of Surgeons in Ireland."

The above notice has excited some curiosity. The simple explanation is the fact we stated last week, that the Corporations oppose the Bills of Lord Elcho and Mr. Cowper, and wish the Government to support that of Mr. Headlam. The probable consequence will be that Medical Reform will be staved off for another year. Mr. Walpole's answer was very vague. He distinctly refused to pledge himself to any decided course.

## STATE VACCINATION.

To the Honourable the House of Commons in Parliament assembled, the humble Petition of the President and Council of the Epidemiological Society of London, witnesseth,—

That your petitioners represent a society, founded in 1850, for the investigation of Epidemic Diseases, with a view to their mitigation or prevention.

That one of the subjects which has engaged the most earnest attention of your petitioners has been the great annual mortality occurring in the United Kingdom from small-pox, a mortality which your petitioners believe might be almost, if not entirely, prevented—vaccination, if performed with the requisite care and precaution, being a safe and almost certain prophylactic against small-pox in its fatal form.

That your petitioners therefore attribute the mortality to which they now call your attention, first and chiefly to the neglect of vaccination; and, secondly, to its inefficient performance; and they submit that ample proof of this has been laid before your Honourable House, first in a report presented by themselves in 1853, and subsequently in papers collected by the Medical officer of the General Board of Health.

That your petitioners, having investigated the laws regulating public vaccination in these kingdoms, and the system of administration pursued, find that, while Scotland is destitute of any provision whatever for this purpose, the arrangements in England and Wales and in Ireland are most ineffective, neither providing the constant Medical supervision which is indispensable for the proper diffusion of the blessings of vaccination, and the avoidance or suppression of outbreaks of small-pox, nor giving the needful security for the efficiency of the vaccination supplied. These deficiencies your petitioners have considered in detail in a memorial printed by your Hon. House in 1856.

That the defects complained of, so far as they regard the system of administration pursued, were in no way removed by a Bill passed in 1853 for extending and making compulsory in England and Wales the practice of vaccination; and that, on this account, not only has this Bill (which has nevertheless had a striking and most beneficial effect on the mortality from small-pox) been much less operative than it otherwise would have been, and, in some places indeed, almost entirely inoperative, but also the benefit it did confer is on the decline, the infantile public vaccination having diminished from 65 per cent. of the births, which was the ratio in 1854, to 56 per cent. in 1855, and to 54 in 1856.

That it was, therefore, with the greatest satisfaction that your petitioners observed that a Bill was introduced by your Hon. House to the Government early in the session of 1856, which would in their humble opinion have secured, or laid the foundation for securing a good system of public vaccination in England and Wales: which Bill, however, having passed a second reading has, to the great regret of your petitioners, not been further proceeded with.

That from the time this Bill was first introduced to your Hon. House to the present time, there have perished in England and Wales alone from small-pox between 4,000 and 5,000 persons, at the least (a), chiefly young children; that nearly every one of these lives might have been saved by efficient vaccination; and that, while your petitioners are far from supposing that any change in administrative system would at once have reached all these cases, they can yet most confidently affirm that it would have reached a very large number of them, and that a great saving of life and human suffering might thus, in these two years only, have been effected.

That this loss of life, which might be avoided, is still going on from day to day; and that on account of the decrease in the number of public vaccinations already pointed out, it will in all probability become more considerable; for which reasons your petitioners deprecate further delay, and earnestly pray your Hon. House to take immediately into your consideration this question of public vaccination. Your petitioners are fully aware of the numerous questions to which your attention is called each session, and of the great importance of many of them, but they humbly and respectfully submit that no question can be more important, and that none can less admit of postponement than those which would effect a saving of human life.

And your petitioners, as in duty bound, &c.

(Signed)

B. G. BABINGTON, M.D.

President of the Epidemiological Society,  
on behalf of the Society.

## REVIEWS.

*The Human Mind in its Relations with the Brain and Nervous System.* By DANIEL NOBLE, M.D. Pp. 157. London: 1858.

Dr. Noble is already favourably known to the Profession by his work on Psychological Medicine. In the volume now before us he has laid aside the pathological part of the subject, and has amplified the portion relating to physiology.

The physiology of the brain has always been, and will probably ever remain, involved in a certain degree of mystery. Many of the most profound philosophers of ancient and modern times have analysed and arranged the faculties of the mind, and the anatomy of the brain has been minutely investigated with all the aids which the scalpel, chemistry, and the microscope could bring to bear; but the exact nature of the connexion between the sentient and thinking principle on the one hand, and its material dwelling-place on the other, has never been established by such close and exact arguments as are required in philosophical investigation. The most remarkable instance of attempting to connect mind with matter, and even to localise the mental faculties, was afforded by the investigations of Gall, whose phrenological system obtained the adherence of some, and encountered the opposition of many others, but whose merits as an original investigator of the

(a) This petition was drawn up early in January, but its presentation has been delayed by various causes till the present time; the number of deaths now must be considerably above 5,000.

structure and functions of the brain (apart from his phrenological views), are scarcely yet sufficiently acknowledged. Dr. Noble himself was originally a disciple of the phrenological school, but he has been convinced of the untenable nature of the doctrines propounded, having found that extended experience and observation have not borne out the principles advocated by those who sought to define the faculties of the mind by lines drawn on the exterior of the skull.

Dr. Noble, in renouncing the craniological system of Gall and Spurzheim, agrees with the majority of the anatomists and physiologists of the present day, although he admits that a certain portion of truth underlies the ingenious, though flimsy, superstructure raised by the two German psychologists. While admitting, therefore, as a matter of common observation, that a tolerably capacious head and brain are absolutely necessary for the development of superior intelligence, and that, moreover, a fully developed forehead is usually associated with high intellectual and moral attributes, Dr. Noble disbelieves the theory that separate organs are devoted to distinct mental faculties. Pursuing the same cautious mode of induction in reference to the physiology of the nervous system, and carefully distinguishing those views which are the results of experiment and observation from those which are merely speculative, Dr. Noble describes in detail the different portions of the brain and nerves, which appear to subserve certain special purposes; and, speaking generally, he concurs with most physiologists in believing that the vesicular neurine of the hemispherical ganglia, or, in other words, the grey matter forming the cortical or investing substance of the brain, constitutes the seat of primary change, and is the source from which mental operations originate; while the white matter, consisting of fibres, forms a series of communicating wires, as it were, conveying the mental impressions to the bodily organs, and converting thought into action. Now, in general it is necessary, in order to convert the ideas conceived in the mind into active bodily manifestations, that the will should come into operation; but that in certain cases the ideas alone can excite the bodily functions, has been shown by many recent observations. To this point, especially in connexion with some experiments in mesmerism, Dr. Noble has devoted considerable attention, and in a very interesting chapter of his present work, entitled, "the Physiological Potency of Ideas," he has treated the subject at some length. Among many other instances, a very curious (if true) illustration is afforded by the case of a person who, in a mesmeric sleep, was directed to lift a heavy article from the floor, and was told at the same time that its weight would render the act impossible. Under the influence of the ideas, the person operated upon was unable to lift the supposed weight, which was only a pocket-handkerchief. The converse of this experiment was still more striking, for under the impression that the weight of the substance to be lifted was insignificant, an individual when hypnotized raised with his little finger a heavy mass, which he moved with difficulty when he was in the normal state. To the same category of *ideo-dynamic* facts belong the cases where patients who supposed they were taking sedatives have been composed to sleep by a purgative pill; or others who, supposing that they were swallowing aperients, have been purged by anodynes and astringents. The supposed cures resulting from mesmerism belong, probably, to the same class of *ideo-dynamic* operations, and the follies of homoeopathy may also be traced to the influence of dominant mental ideas upon the bodily functions, inducing persons to believe that changes are wrought in the organism by infinitesimal doses of inert matter, while the changes are really due to the fanciful *ideas* of the patient. It is obvious that this direct influence of the ideas over the bodily functions, without the intervention of the will, is a subject full of importance both to physiology and pathology, and our knowledge of this curious relation is, in great measure, due to the researches of Dr. Carpenter and Dr. Noble, whose views are not yet, we believe, fully known and appreciated by the Profession.

Upon the functions of the sympathetic system, which occupies so prominent a place among the nervous structures, Dr. Noble writes with caution, as he believes that the exact office of the ganglia and nerves of the sympathetic has not yet been determined, although, from cumulative evidence, it may be assumed that this system exercises a controlling influence over the processes of circulation, nutrition, and secretion.

In treating of the functions of the spinal cord, ample justice is done to the researches of the late Dr. Marshall Hall.

We cordially recommend Dr. Noble's work to the notice of the Profession, and to all who wish to ascertain what is known of the relations held by the mind to the corporeal structures. Those who expect to find in its pages new and speculative hypotheses will undoubtedly be disappointed; but those who wish to become acquainted with the cautious deductions which may be drawn from a careful inquiry into the mutual relations existing between the soul and its earthly tenement, will be amply gratified by its perusal. Dr. Noble insists, perhaps rather unnecessarily, that there is nothing in physiological psychology which ought to suggest even the approaches of materialism. "In the present sphere of existence," he observes, in concluding the book, "the mind is manifested through organic intervention; a thousand circumstances prove the fact. It is yet no more the case that the material brain is the conscious principle, and its separate parts divisions of the mind, than that the music of the lyre inheres in the instrument, and that the melodies which art can elicit from it are self-produced by the particular strings."

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### ON MENSTRUATION DURING PREGNANCY.

By Dr. ELSÄSSER.

This contribution to a disputed topic is founded upon 50 cases, extracted from the journal of the Stuttgart Lying-in Hospital, cases which are said to rest upon the most certain information. The subjects were 15 primiparæ and 36 pluriparæ, who, with the exception of two women (aged 36 and 41) were between 20 and 30 years of age. Of the 51 children born, 34 were boys and 17 girls, 36 being mature and 15 immature. The menstruation during pregnancy occurred in 50 women, in the following manner:—once in 8, twice in 10, three times in 12, four in 5, five in 6, eight in 5, and nine in 2. In 13 cases the peculiarities of the rhythm of the discharge were inquired into, and the rhythm was found regular in 4, in 1 it occurred at the 6th week, in 3 there were pauses between the epochs, in 2 the menstruation first appeared after the 2nd month, in 2 after the 4th, and in 1 after the 6th month. In one case the menstruation first appeared in the middle of gestation, and henceforth came on every 4 weeks, lasting 3 or 4 days. The child perceived but feebly at first, was strongly felt during the last 4 or 5 weeks. Hæmorrhage occurred twice within a week before delivery, but a mature, living infant was born. Indications as to the amount of discharge was furnished in 26 cases, and in 18 of them it was less than in the non-pregnant condition. The weight of the 35 mature infants varied from 5lbs. to 9lbs.

Dr. Elsässer observes that although he is unable to state the proportion of cases in which menstruation occurs during pregnancy, it is by no means so exceptional an occurrence as supposed by some authors. It occurs more frequently in pluriparæ than in primiparæ; and it takes place much more frequently during the first half of pregnancy, and especially in the earlier months of this, than during the latter half. The amount of discharge too is smaller than in normal menstruation. The duration of the pregnancy was normal in more than two-thirds of these cases (36), while in nearly one-third (14) of the cases it was interrupted, in 4 during its first, and in 10 during its latter half. As regards the development of the child, which by some authors has been supposed to be impeded by the occurrence of menstruation, this was found to be normal, or more than normal in three-fourths of the cases.—*Monatschrift für Geburtskunde. Band. 73. Pp. 401—408.*

#### EXCERPTA MINORA.

*A cheap Collodion.*—Steep white printing or machine-paper in concentrated sulphuric acid from five to eight minutes, and then wash and dry it. It becomes now as stiff as parchment; and if we cut it up small and digest it in ether, we obtain a substance not very different from common collodion, at a much cheaper price.—*Buchner's Report. No. 3.*

**New Colouring Substance.**—Dr. Waltl states, that a syrup prepared from the berries of the *phytolacca decandra* (Linn.) forms the best substance for imparting a most beautiful red colour to medicinal or other substances. A very small portion colours a large quantity.—*Buchner's Report*, No. 3.

**Corrosive Collodion in Nevus.**—Dr. Cösfeld reports, that he has derived great benefit from the employment of this substance (corrosive sublimate one part, and collodion eight parts) in the treatment of nevus. The eschar falls off from the tenth to the fourteenth day, and is not followed by suppuration. No pain is produced, and scarcely any cicatrix is left. For very small nævi one pencilling is enough, but in larger ones this has to be repeated: and in these it is best to effect their destruction gradually.—*Berlin Med. Zeitung*, 1857, No. 34.

**Painless Caustic.**—M. Picdagnel, after various trials, has succeeded in producing a caustic that may be employed, causing little or no pain. It is formed of three parts of the Vienna caustic in powder and one part of hydrochlorate of morphia, intimately mixed together, and then made into a thick paste by means of chloroform, alcohol, or water. It is applied to the skin on diachylon. A black eschar is produced in fifteen means, increasing in thickness with the duration of the application. The morphia mixed in the same proportions with powdered cantharides, prevents pain during the rising of a blister. M. Picdagnel, who at present has only used this means for the production of issues and blisters, states that the action of the morphia is merely local.—*Gaz. des Hop.* No. 39.

**Removal of a bone from the Œsophagus.**—Dr. Rice was called to an old lady the fifth day after she had swallowed a small piece of bone in some chicken broth, and which had become lodged in the Œsophagus, about two inches below the top of the sternum, completely preventing deglutition. After trying other modes of extraction he resorted to the following one with success:—Taking a piece of dry sponge about an inch long, and so shaped as to fill one-half of the Œsophagus, he tied it to the extremity of a whalebone sound. Turning back the head of the patient, he passed it dry as rapidly as prudent, until he became certain it had gone beyond the bone. A little fluid was now poured in, which enlarged the sponge to twice its former size, and on withdrawing this the bone was brought out with it.—*Boston Journal*, vol. lvii. p. 356.

**Apoplexy from violently shaking the head.**—Professor Childs, of New York, relates an interesting case of fatal apoplexy of the cerebellum. A young lady, in the summer of 1853, to amuse an infant shook her own head rapidly and violently a great number of times. Faintness and vomiting followed, and she was confined to bed during several days, and when she got up again staggered in walking. A seton alone did her temporary service; and December, 1854, Dr. Childs found she could not walk without help, was growing rapidly blind, and complained of dull pain in the occiput. She died from convulsions, January, 1855, the intellect continuing unaffected. An old, hardened clot of blood, the size of a large walnut, was found in the centre of the cerebellum, bathed in nearly two ounces of yellow serum inclosed in a cyst.—*Ibid.* p. 536.

**Florogene in Intermittent Fever.**—Some of the physicians at Cincinnati report very flattering success from the employment of florogene, the active principle of the apple-tree bark.—*Ibid.* vol. lviii. p. 28.

**Iodine in Snake-bite and Bites of Rabid Animals.**—Dr. Brainard, of Chicago, has for years used and pretty clearly demonstrated the value of iodine as an application to snake-bite. Dr. Massey commenced early in 1853 to treat wounds made by rabid animals with tincture of iodine. He applies it to the wound every five minutes for an hour, then an emollient poultice, and the iodine every hour for the next ten hours, then every four hours for the next twenty-four, and changes the poultice every twelve hours until the wound heals. He has employed this treatment with success in a number of cases. Some of the animals he has reason to believe were rabid, and others, perhaps, not so.—*Ibid.* p. 48.

**Granular Eyelids.**—Dr. Pitcher, of Detroit, recommends a solution of iod. zinc (℥j. or ʒj. ad ʒj.), applied with a fine camel-hair pencil. The editor of the *Western Lancet* uses perchloride of iron, previously scarifying the lids. Dr. Fenner, of Memphis, uses internally a decoction of *phytolacca decandra*, which is probably chiefly beneficial in cases associated with rheumatic disease.—*Ibid.* p. 48.

## GENERAL CORRESPONDENCE.

### ENCOURAGEMENT OF HOMŒOPATHY.

[To the Editor of the Medical Times and Gazette.]

SIR,—You have opened your columns for the discussion of a most important point of Medical ethics, and I am sure that every well-wisher of his Profession will thank you for bringing the subject thus boldly and uncompromisingly to the bar of Medical opinion.

I cannot but regret, however, to find that such a matter needs discussion. I could have hoped that the position of Medicine in relation to Homœopathy had been so clear and evident, as to leave no kind of room for doubt or hesitation, in the mind of Surgeon or Physician, how he should comport himself when brought into contact with the disciples of Hahnemann. I could have hoped, from the high position of dignity and of honour which our Profession at all times assumes—in the mouth of its leaders—from its constant repudiation of any association with the tricks and villanies which flourish in the world around us, that we should have been spared the humiliation of dallying, even in discussion, with any such alliance as Homœopathy.

The roads of Medicine and of Homœopathy are as diverse as the extremes of good and evil. One is the honest and humble search after truth, and the application of the results, thus conscientiously attained, to the cure of the ills that flesh is heir to—a true religion. The other is a degrading, presumptuous, and wicked cheat—a superstition. It is degrading because men who profess it, under the garb of science, practise upon the credulity of the ignorant masses of mankind, and thus, instead of elevating, assist in the degradation of their species. It is wicked, in that these men, sheltering themselves under, and deriving a cover of decency from, their nominal connexion with the legitimate body of Medicine (which utterly repudiates them), assume a false position, and act a dishonest part before the world. It is presumptuous, because it professes boldly to do what is impossible. This, at least, is what every member of our Profession must think of Homœopathy, so long as he truly remains a member of it. What possible dealings, then, can he have with such a thing?

You have well said it: Men who practise Homœopathy are either dupes or swindlers. With medicine they can have no kind of communing. And, I again repeat it, it tells not well of our Profession that we should need to be discussing at this day what our relation to Homœopathy should be.

What part the Physician should play in the presence of this delusion, one of the honoured heads of our Profession, Dr. C. J. B. Williams, has shown us by example. He peremptorily refused to meet the Homœopath, and was honoured by his Profession for doing so. And who can doubt but that his influence has prevented many a smaller man from falling into the temptation? But how is the Surgeon to act? He, we shall be told, is differently circumstanced. I utterly deny it. Men may raise a plausible argument to cover any doubtful action, as correspondents in your last Number, in my opinion, have done. Nothing is easier; and right principles may be thus obscured, but they cannot be stifled. Called upon suddenly to save life or relieve suffering, the Surgeon is undoubtedly bound to obey the call; but he is not bound, in doing so, to shake the hand of fellowship with the practitioners of this homœopathic subtlety. He may do his duty, though accidentally placed face to face with Homœopathy, and yet repudiate the thing. His manifest duty is,—and the higher his position, the more strictly is he bound to the duty,—while relieving his patient's suffering, clearly to proclaim his entire antipathy to the chicanery; and never even for an instant, or in the smallest particular, to allow the delusion to come between him and his patient in the treatment of the disease. Is any man in his senses to be told, that the Surgeon who meets a Homœopath without repudiating Homœopathy does not patronise Homœopathy in the opinion of the world? And does a Surgeon never administer drugs? This great Surgeon, the high world of fashion will naturally say, does not deride Homœopathy; he is free from the bigotry of his Profession; he has none in him of that narrow-minded sectarian spirit which repudiates great discoveries; he has met, and meets freely, our favourite Homœopath; he, at all events,

evidently gives his assent to the wonderful doctrines of Hahnemann. Yes! this is how the world will argue; and this is how Homœopathy is propagated, and is floated gaily on before the breeze of fashionable fancy! because men will grow rich at any price.

You may well say that the rising men of our Profession have a hard battle to fight. Hard indeed, if, while struggling for a position, they are deserted in the field of honour by their natural leaders, and left alone to sustain the unequal combat. I have known a leader come in and take the place of a junior Surgeon, who refused to join the family Homœopath in consultation; and, if report speaks not untruly, there is at least one consulting Surgeon in London who once repudiated an offer which would have brought him great gains as a Surgeon, but which would have rendered him little better than surgical lacquy to the Homœopaths; and another, perhaps, now occupies the position then refused!

I cannot doubt, for a moment, what the verdict of the Profession will be. It will have no dealings with the unjust thing, and it will not permit any man of high standing in our art to play with it. Let Homœopathy and aristocratic ignorance, knavery and credulity, form their combinations; but let Medicine keep her hands clean. Never was there a time when Medicine had more cause to demand from her followers *vitam puram prestare* (as enjoined by the Father of our art) than now. We see around us in every quarter busy quackery reaping rich harvests. The more unblushing the boastful impudence of pretence, the more widely does credulity open its arms to receive it. Lies, arrogance, and craft, enter freely where modest truth beats a retreat. In the face of this array of opponents, let us at least be true to ourselves. Let us insist that the line of demarcation be clearly and distinctly defined between them and us. Let it be loudly declared by the Profession, that there can be permitted no semi-alliance with the imposture. Who, indeed, are these carriers-on of the deceit, that we should use gentleness towards them? They have robbed a fictitious title from us, under which they stand before the world. Is there one of them who has driven a single nail into the edifice of Medicine? Well! it is at all events something of a boast to Medicine, that her own sons have been hitherto true to her; and this is a fact of which we may well be proud, that all the great deeds and discoveries which have advanced and adorned the science have been the offspring of their hands. It is a curious and most instructive truth, that of the grand makers of impossible cures, the high-priests of Arcana, the boasters and cheaters who sport or who have sported at large and with infinite success in that well-stocked preserve, human credulity—that of these, not one has done a single deed, or made a single discovery, tending to the progress of Medical knowledge, or has left behind him a name honoured by those whose honour is of price. Is there one of them who at this moment is known in the world of science—who has a reputation which reaches beyond the atmosphere of the street in which he lives?

Your correspondents, "*Vox Populi*" and "*Justa aut nihil*," are not persons with whom the Profession can entertain argument. The former is "a Patient, not a Medical man," and he must not be surprised if we decline his arbitration in a matter which touches our honour, and about which he is, of necessity, incapable of judging rightly. He, like the rest of his class—the populus, which ever revels in deception—is at perfect liberty to indulge in Homœopathic consultations, but he must also allow us equal liberty in refusing them. Your other correspondent, "*Justa aut nihil*," is, from the signature, evidently a female or nothing; the kind, tender, compromising spirit of the sex breathes out in every line. Her letter is what a woman's should be—an appeal to the heart, and not to the reason. Let me fondly hope that my Profession will produce no pen to back the sentiments these letters utter. The tale we are told about the sufferings of humanity, and the duty of giving instant aid to its sorrows in an unquestioning spirit, is all sheer claptrap. It is nothing more than a sort of salve, with which he who would pluck some of the sweets out of Homœopathy anoints his conscience. Whoever confers or compromises with an Homœopath, strikes a dagger into the heart of honest medicine, and stands convicted before the world, a patron of the deceit and a promoter of it. If, to-day, he has dealings with the globulist farce, why, to-morrow, should he not be found clinically consulting with the thousand beastly advertising quacks of the day? They also can produce their M.D. and their

M.R.C.S. diplomas, and therefore, according to the views of your amiable correspondents, are equally entitled to all consideration from us. And will not the Duke of this and the Earl of that naturally argue, when they see this communion between the heads of our Profession and the Homœopath, "Why, on earth, should we not admit the Homœopath into our army and our navy? The leading Doctors in London patronise the thing, why should not we? Excluding it is nothing but persecution; I will speak about it to Sir John Liddell and Dr. Smith to-morrow."

He who stands high in our Profession should never forget that he owes a deep debt of gratitude to his brethren for placing him there. They have recognised his merits, and they have rewarded him; but between them and him there is silently sealed a solemn compact, that he should in his high position illustrate widely to the world the honour of the Profession; that he should stand out in relief, an example of professional worth and lofty professional bearing. There are men who stain their hands and dabble with this thing, because the *res augusta domi* urges them; such persons we may pity in despising. But I do sincerely hope that they who do the evil without excuse—who betray the sacred trust of the Profession's honour (which, by the very fact of their high position, has been placed in their sacred keeping)—will still find our body good enough, and wise enough, and powerful enough firmly to resent the injury inflicted on it.

I am, &c.

A JUNIOR HOSPITAL PHYSICIAN.

London, April 20, 1858.

[To the Editor of the Medical Times and Gazette.]

SIR,—You seem to have overlooked the following letter to Dr. Pratt, by the wife of the gentleman of the patient near Stamford, to whom Mr. Fergusson was called by Dr. Bell, and as it has been published I think the following extract is worthy of attention:—

"London, Good Friday.

"Sir,—I have seen Mr. Fergusson this morning, who told me of your letter to him. . . . We did not send for Mr. Fergusson: Dr. Bell brought him, not knowing there was a Surgeon in Stamford liberal enough to meet him. When Mr. Fergusson came, he said Mr. Jackson's skill was equal to his own, and that there was no occasion to have brought him down, and that he was accustomed to meet homœopathic doctors constantly. Allow me also to tell you that Dr. Bell and Mr. Jackson entirely agree about the medical treatment of the 'gentleman;' and that Dr. Bell is now attending him here."

Now, Sir, I think some explanation of this letter is due to the Profession from Mr. Fergusson. Is it true that he is accustomed to meet homœopathic doctors constantly? Let me also ask, is it true that for months past he has been in frequent attendance on the Duke of Beaufort with the homœopathic Doctor Quin? When these questions have been answered I and other 'honourable gentlemen who act with me' will know how to act. I am, &c. VOX FAUCIBUS HÆSIT.

April 22, 1858.

[To the Editor of the Medical Times and Gazette.]

SIR,—In common, I am sure, with a very large body of the Profession, I rejoice to find that you, at least, have had the courage to seize the bull by the horns in the question of Medical men attending patients with Homœopathic practitioners. Allow me to suggest that the Medical societies of London should be specially summoned to take this subject into consideration; let the question be fairly argued; let us hear what each party have to offer in vindication of the conduct they are daily pursuing. There is no use in the question being blinked any longer, merely because those enjoying large practice are in the habit of meeting Homœopathic practitioners, or what in their own language they call attending surgically to a case while an Homœopath attends medically. This degrading of the art of Surgery I protest against, and call upon the Profession to join in protesting against, as most injurious to Surgery as a science. Your correspondents of last week, "*Vox Populi*" and "*Justa aut nihil*," surely cannot hoodwink the Profession with such miserable special

pleading as they make use of. It is quite true, that there is no use in the Junior-Surgeons refusing to attend patients surgically who are attended medically by Homœopaths, while they are met daily by the answer, "Oh! Sir Charles Locock and Mr. Fergusson meet them!" This would, indeed, bring us back to the days of Barber-Surgeons, when we only followed the orders of the Physicians—Go on, Sir, follow this case to the end, and you will be supported by all the respectable members of the Profession, whose motto should be—

QUODCUNQUE OSTENDIS MIHI SIC INCREDULUS ODI.

P.S.—The Reading resolutions will, no doubt, do good; but allow me to suggest that future resolutions should run thus:—

"That any Physician or Surgeon meeting in consultation, or acting with, or attending a case with an Homœopathic Practitioner, be not consulted by us, or met in consultation."

### IRIDECTOMY.

[To the Editor of the Medical Times and Gazette.]

SIR,—In a recent number of the *Medical Times*, you have published an article on the operation of Iridectomy in Irido-choroiditis and glaucoma as recommended by Professor von Gräfe, of Berlin, in which the authors, Messrs. Wharton Jones and Mackenzie, reflect in anything but measured terms on the professional reputation of that gentleman. I do not mean for one moment to dispute what the above celebrated writers have advanced, although I have seen too many cases of glaucoma cured by Professor Von Gräfe's operation, when everything else had failed, to coincide in their views; I merely wish to draw the attention of your readers to a fact.

Mr. Wharton Jones, in his "Principles and Practice of Ophthalmic Medicine and Surgery," says in speaking of internal arthritic ophthalmia (glaucoma), "The prognosis is altogether unfavourable; treatment has little influence on the disease; at the most it can merely mitigate or retard. Vision is sure to be abolished by a renewed attack. Eventually the eyeball may be destroyed." He, however, agrees with Dr. Mackenzie, in the article which has just been published, that "by puncturing the eye," and "proper Medical treatment," the disease can be cured. This is somewhat inconsistent with the high attainments and professional repute borne by this gentleman, and scarcely comes up to our English ideas of straightforward dealing.

I have only to add that Professor von Gräfe continues to perform his operation with success on patients who come to him from all parts of Europe, and where every other treatment has failed; and that the operations and after-treatment are not only witnessed by me, but by crowds of professional confrères, from all parts of the civilized globe.

I am, &c.

JAMES G. HILDICE, M.D.  
Dublin.

Berlin, April 17, 1858.

### CONJUNCTIVAL SUTURES.

[To the Editor of the Medical Times and Gazette.]

SIR,—I am induced to send you a short communication, in consequence of an allusion which has been made to me in your last impression, in a note from a correspondent, respecting the use of sutures in the Surgical treatment of Strabismus.

It seems, then, that a late writer states in his monograph, that I am in the habit of using sutures in the operation for squint. A professional brother on the other side of St. George's Channel, of talent, high attainment, and wonderful industry, thinks that as he was the first in her Majesty's dominions to publish an account of such a method, his name should have been mentioned in the little book alluded to. This is all well enough, and does not need comment from me.

I have never claimed any originality for sewing up anything, nor have I been accused of such. I am not, therefore, writing in controversy. But, Sir, I am glad of this opportunity of saying a few words about employing the stitches. Ample practice, combined with experiment, study, and investigation, have

convinced me that I serve my patients' welfare, and my own reputation the best, in instances of internal squint, by operating in a particular manner, and using sutures. I shall be very concise, as I have neither time nor inclination for a long description.

I make a small vertical snip in the conjunctiva, just over the insertion of the internal rectus, together with the sub-jacent tissue; secure the muscle with a blunt hook, and sever it from its attachment to the sclerótica with a pair of blunt-pointed scissors. Thus I take great care not to cut or disturb the subconjunctival fascia more than can be helped, nor to divide more of the conjunctiva than covers the muscle. I unite the external wound by one or two sutures, generally two, and place them at the very margin of the edges, and make the adaptation as accurate as I can. I was long aware that sutures had been used or recommended before I tried them, although I do not remember whence I got my information. In my work on the eye I have alluded to M. Cunier as advising them. In all probability I had read Mr. Wilde's reports about the matter, as I peruse his productions when I meet with them; but I do not remember the fact. I was deterred from using the sutures, on account of dreaded irritation to the eye. I had not seen them applied, nor had I met with any one who could recommend them from personal knowledge. At last, being greatly dissatisfied with the gaping wound that resulted without them, and suspecting that far more perfect results might be obtained with them, I tried the practice. I was much surprised with the rapidity of union that ensued, and not less highly pleased with the several advantages that followed, such as quick healing, an absence of fungous growth, and no interference with the natural folds of the conjunctiva at the inner canthus. I have not found that the threads irritate; patients are not aware of their presence. At first, I used to remove them on the third day; but now I allow them to ulcerate away, a process that is generally accomplished from the third to the fifth day. It appears to me, then, that I adopt a plan by which I am most sure that the muscle is entirely divided, and by which, at the same time, there is the least violence inflicted consistent with that division.

I am, &c.

HAYNES WALTON,  
Surgeon to St. Mary's and the Central  
London Hospitals.

69, Brook-street, Hanover-square, 20th April, 1858.

### CANCER CURING.

[To the Editor of the Medical Times and Gazette.]

SIR,—The accompanying "work" was found in the letter-box of a neighbour of mine. It is entitled, "Extracts from the Report of the Surgical Staff of the Middlesex Hospital. By J. Weldon Fell, M.D. To which are added Extracts from Journals, &c." The following extract from these extracts will serve as specimens of the whole:—

"There lately has arrived in London one of these philanthropists from New York, a Dr. Fell, who cures cancer by *knifeless* extraction. Every Tuesday he invites his Medical brethren to visit his surgery, No. 70, Warwick-square, Pimlico, where they may freely inspect the different stages of the cure in the patients who assemble there for examination, between two and four o'clock. And certainly there never was seen a more joyous set of sufferers, most of them residing for a time under his own eye, in the pretty cheap lodgings with which Cottage-road abounds. The doctor places them under no restrictions of diet or medicine; they are allowed to walk or drive according to their habits and strength, and are not prevented by inconvenience from attending, if they desire it, Divine worship. To say they do not suffer pain would be untrue; but the paroxysms in most cases are not greater during the progress of the cure than before it commenced. They are all borne up by hope, and released from the horror of the knife, which, even with the blessing of chloroform or mesmerism, is a fearful ordeal to undergo—and such operations are not always radical cures. Dr. Fell asserts that, even if cancer appear again, the same remedies can be used without injury to the constitution, it having previously received no shock to the nervous system, either by the anticipation of the usual operation, or the pain from the dressing of wound

caused by the knife. Physicians of the highest celebrity have visited this gentleman, and have honourably come forward with their testimony of the extraordinary results from this treatment. Sometimes the cancer comes out whole, like a huge corn; sometimes in quarters, like the divisions of an orange. These are preserved in glass cases, for the inspection of any one who likes to visit the Doctor."

"From the *Lancet*, January 31st, 1857, page 128.

"We understand that Dr. Fell, the American physician, whose treatment of this disease has of late been so much spoken of in London, has made an arrangement with the authorities of the Middlesex Hospital, by which he has taken charge of a certain number of cases in the Cancer wards of that establishment, for the purpose of subjecting them to the action of his remedies.

"Dr. Fell has communicated, in confidence, the particulars of his treatment to the surgical staff, who will watch the cases, and report upon the results.

"This experiment reflects great credit on the Medical officers of the Middlesex Hospital."

"We of the *Profession profess* philanthropy, and man is never so God-like or philanthropic as when using laudable means, in alleviating the miseries of suffering humanity; and this I cannot more *effectually effect*, than by recommending him to those who are so unfortunate as to be afflicted with malignant ulcerations of every grade and character, they may come confidently expecting relief.

"Very respectfully,

"John A. Wilson, M.D."

The preface also is curious:—

"So many persons having sent to me for copies of the 'Report of the Surgical Staff of the Middlesex Hospital'—and a number of patients having applied to me in a suffering condition, after having undergone treatment by their surgeons with a view to the removal of their diseases by my plan of treatment, and, failing in the attempt, thereby bringing discredit upon it—I am induced to publish a few extracts from the journals of this and my own country, together with such extracts from the 'Report' as will be interesting to the public (the remaining part of the 117 pages containing only such matter as will be interesting to the Profession).

"The cause of the failure of so many Surgeons is no doubt explained by a clause in the Report, viz.—

"As much of the success of this treatment depends upon the mode of practising it,' &c. and as I do not think I should be held responsible for the 'mode of practising it' pursued by others, I have considered the statements contained in the following pages but just to myself and 'the treatment.'

"Another matter has been misrepresented by nearly every journal that has mentioned my connexion with the Hospital, viz. that I made the first overtures and sought the connexion. The fact is, I knew nothing of the Hospital, or of any one connected with it, until I received the following communication from the Board of Governors:—

'Middlesex Hospital,

'July 17th, 1856.

'Sir,—I am directed to inform you that the Board of this Hospital has been apprised, by one of its Governors, of your remedy for cancerous tumours, and the Board is anxious to learn if it will be agreeable to you to apply your remedy to some patients in this Hospital; and, in the event of your doing so, and the remedy proving to act satisfactorily, you would subsequently supply it to the Hospital, to be used under the direction of the Surgeons of the Hospital.

'I have the honour to be, Sir,

'Your most obedient servant,

'Dr. Fell.

'Alex. Sheddon,  
'Secretary.'

My object in reproducing these quotations *verbatim* is that the Surgeons of this and other countries may estimate at his proper value the American luminary who has reflected such "great credit on the Medical officers of the Middlesex Hospital."

I am, &c.

VINDEX.

April 16, 1858.

COLLEGE OF SURGEONS.—The Jacksonian Prize has been awarded to Alfred Poland, Esq., of Guy's Hospital, for his essay on "Gunshot Wounds, and their Treatment."

## REPORTS OF SOCIETIES.

### ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

TUESDAY, APRIL 13, 1858.

Sir C. Locock, Bart., President, in the Chair.

A paper by Dr. TYLER SMITH was read on

#### A CASE OF COMPLETE INVERSION OF THE UTERUS OF NEARLY TWELVE YEARS' DURATION, SUCCESSFULLY TREATED.

The author commenced the paper by referring to two cases of inversion of the uterus, published in the "*Medico-Chirurgical Transactions*," in one of which extirpation was practised with recovery of the patient, while in the other, treated by palliative measures alone, death ensued eighteen months after delivery. He brought forward the present case as illustrating a new principle of treatment. Hitherto the cases in which re-inversion has been accomplished have been chiefly limited to cases of recent origin. It has been held that unless the inversion could be reduced soon after the accident, there was little hope of accomplishing it, death generally occurring at periods varying from a few months to five or six years. The operation of extirpating the uterus by ligature is a very serious one. Of thirty-four cases of extirpation, twenty-seven recovered and seven died; in nine of these cases the inverted uterus was mistaken for polypus. The subject of the present case was delivered, at the age of eighteen, of a first child, and inversion occurred at that time, but was not suspected by her attendant. When at length an examination was made, a tumour was found in the vagina, but the opinion of those who saw the case was divided between polypus and inversion. Flooding continued to a great extent for nearly twelve years, during which time she was never for a single day without sanguineous discharge. All attempts at replacing the uterus by those who considered it a case of inversion failed. The patient was sent to the author of the paper in September, 1856, by Mr. Griffith, of Port Madoc, North Wales, under whose care she had been for a short time. The symptoms of anaemia existed in the most marked degree. She was subject to epileptiform and convulsions, and frequent faintings. The drain of blood seemed to replace the other secretions to a considerable extent. She passed very little urine, and frequently went twenty-four hours without micturition. On examination, the uterus was found to be completely inverted, the neck of the uterus and the os uteri being very small and rigid. The author determined to attempt its reduction by continuous pressure, with the intention of dilating or developing the os and cervix uteri. With this object the right hand was passed into the vagina night and morning, and the uterus squeezed and moulded for about ten minutes at a time. Chloroform, which had been found so useful in cases of inversion of shorter standing, was not used, because of the feeble state of the heart and circulation, and the comparative absence of pain. In the intervals between these manipulations, in which the author was assisted by Dr. Vernon, the vagina was distended, and firm pressure exerted upwards by a large air pessary. These means gradually dilated the os uteri to such an extent as to allow of the partial return of the uterus, and on the eighth day from the commencement, complete re-inversion took place. The subsequent recovery of the patient was perfect. She has since menstruated regularly, and is in excellent health. The author combats the prevailing notion as to the immobility and unyielding condition of the os uteri in long standing cases of inversion, alluding to the readiness with which the uterus increases, diminishes, and alters in size, under appropriate stimuli. No amount of force will suddenly reduce a case of chronic inversion, but he believes that by air or fluid pressure, so as to convert the fundus and body of the uterus into a wedge, the os uteri may be slowly enlarged in any case, so as to admit of re-inversion. Since the presentation of the paper, the author has been informed that the patient is now in the fifth month of pregnancy. The paper concluded by a reference to other conditions, in which air or

fluid pressure had been of service, such as the arrest of flooding in abortion, placenta prævia, the expansion of the pelvis in cases of high deformity from mollities ossium, and the induction of premature labour.

The PRESIDENT said the author had observed in his paper that, owing to the condition of the patient, he did not think it prudent to use chloroform. He was evidently aware that cases had been recently recorded in which inversion of the uterus of long standing, though not so long as in the present instance, had been completely cured by pressure with the hand, under the influence of chloroform. He wished to ask the opinion of the author as to whether the use of chloroform would not cause the pressure to be effected in a very much shorter space of time, with much less distress to the patient, and perhaps even with more safety.

Dr. TYLER SMITH said his reason for not using chloroform was, the extremely feeble state of the circulation. He should have been afraid to keep the patient under the influence of chloroform for the time necessary to manipulate the uterus. Besides, the os uteri was so small that it would have been impossible to have done it at one or even at several sittings. At first, he could make no impression whatever, and he believed he could not have returned the uterus by pressure with the hand alone. It was only after the continuous use of the air pessary that he found the tumour receded at all. The reason why the pessary was forced through the os uteri, he believed was, that by the influence of the pressure, the os uteri was developed. It was by the process of development, rather than by the operative pressure, that the uterus was reinverted. Then, again, the operation not being painful, there was no bar to the use of considerable efforts to reinvert the uterus. The process of reinversion had often been tried in her case.

The PRESIDENT: With chloroform?

Dr. TYLER SMITH: Without chloroform. The use of chloroform, he conceived, would be in permitting the relaxation of the os uteri; but in this case the os uteri was so small, that dilatation at any one sitting would not, he believed, have effected the object.

Dr. SNOW did not think that the slow state of the circulation had been any bar to the administration of chloroform for ten minutes or so during manipulation. He had given chloroform to several patients, in operations for hæmorrhoids, who were reduced to the lowest state from previous hæmorrhage, and anæmiated to the greatest degree, and he never saw any ill effects from the chloroform in those cases.

Dr. T. SMITH asked Dr. SNOW if he would use chloroform for a patient subject to repeated faintings. He once saw chloroform used for the extraction of teeth in the case of a lady who had lost a very large quantity of blood by abortion, and he certainly feared that she would die. From what he had seen in that and in other cases, he should fear the use of chloroform for a patient who had lost blood to such an extent as to be frequently subject to fainting. The patient whose case he had described scarcely passed a day without fainting.

Dr. SNOW believed that a patient who was liable to fainting, would get through an operation better with chloroform than without it; but of course there was a limit to what might be done either with or without chloroform, when the patient was in an extreme degree of faintness.

Dr. MACKENZIE said the author had described the case as one of complete inversion, but it appeared to him (Dr. Mackenzie) that it scarcely came within that category. The late Dr. Hamilton of Edinburgh published a case of complete inversion, in which, upon simple treatment, the patient was enabled to live fourteen years with little or no inconvenience. The distinction he laid down between partial and complete inversion was, that partial inversion was attended with hæmorrhage, while complete inversion was not necessarily so attended. The history of the case, as detailed by Dr. Smith, brought it within the category of cases that he (Dr. Mackenzie) had seen, in which the inversion was partial, in which the body or cervix of the uteri was constricted by the os, and in which hæmorrhage necessarily occurred. He had lately met with a case of inversion that ended fatally. He was not at the time aware that inversion or reposition had been effected after a lengthened period; but he found on consulting various Journals that from periods averaging from three months to eighteen months or two years, reposition had been effected under chloroform without difficulty by mere manipulation.

(To be continued.)

## THE LATE PROFESSOR CHOMEL.

THE funeral of this esteemed professor was attended by a large concourse of persons celebrated in the world of science and medicine. The Faculty of Medicine, of which he once formed so distinguished a member, was represented by twelve professors in their robes; and M. Grisolle expressed in eloquent and feeling terms the sense they entertained of the loss they had sustained. M. F. Dubois, also, the Secretary of the Academy of Medicine, gave a short account of the principal events of the active career of the deceased professor.

From these sources we gather that M. Chomel, born in Paris in 1788, belonged to a family that had already produced accomplished practitioners, among whom were the physicians to two kings, Pierre Chomel, the author of the "Plantes Usuelles," a pupil and friend of Tournefort, and the founder of the Ecole de Pharmacie, and Jean-Baptiste Chomel, one of the historians of medicine. Receiving a solid education from his father, himself an accomplished man of letters, he early entered upon his hospital career. By hard labour and irreproachable conduct, he soon placed himself in the front rank of students. Interne and laureat in 1811, he received the title of Doctor two years later, and his thesis on that occasion, under the title of "*Essai sur le Rhumatisme*," continually quoted since, revealed the lucidity and rectitude of ideas that afterwards became so manifest. Early chosen physician to la Charité, he commenced courses of lectures on internal pathology, the success of which is still remembered; and he enriched Medical literature with various memoirs, all marked with the stamp of sound observation, a work on Fever, and a treatise on General Pathology. The latter, translated into various languages, has reached a fourth edition, and is everywhere received as an eminently classical production, and as a most invaluable introduction to the study of diseases.

These various works had conferred upon their author so high a repute that in 1823 he was chosen to fill one of the twenty-four places of *agregé* then created; and three years later, upon the death of the great author of the *Traité d'Auscultation*, Chomel was chosen by the faculty to occupy the chair of clinical medicine, rendered so illustrious by the genius of Laennec. He had now a vast theatre for the development of his remarkable qualities. His success, which never afterwards failed him, was so great that, placed in the same hospital, the Hotel Dieu, where Dupuytren until then had reigned alone, he became enabled to divide public favour with the great surgeon, and was not eclipsed by a teaching, then unequalled in Europe. Who indeed was better fitted than he to direct the young in so difficult an art as clinical teaching? The severity of his intellect protected him from the intoxication of hypothesis, as the soundness of his heart did from therapeutical extravagancies. An impassible and sagacious observer, he interrogated nature with skill, ingenuity, and perseverance, revolving all the facts, the better to estimate them, and attack them on their vulnerable side; as apt at grouping as at analysing phenomena so as to arrive at their individual value, he always remained within the limits of observation, verifying, but never supposing. In his lectures he never spoke as one inspired, he was but the *savant* who reasoned. Thus what prevision was observed in his diagnosis, what perspicacity and reserve in his prognosis, what wisdom in his therapeutical indications! Then, again, how this consummate physician excelled in moral medicine. There are ills not to be succoured unless we know how to partake of them; and Chomel was always able to find in the goodness of his heart, and the resources of his mind, sovereign means to raise the courage of even the most dejected.

Succeeding Royer-Collard at the Académie de Médecine in 1830, he was some time after advanced to a still higher honour, as member of the *Conseil Supérieur de l'Instruction Publique*, and he was there, as elsewhere, admired for the justness of his understanding, the excellence of his judgment, and the wisdom of his counsels. What more could be wanting to complete his happiness? The possessor of an immense practice and a large fortune, confided in by the highest personages, and loaded with honours, it would seem that all that could be desired was his. But reverses were in store for him. At the revolution of 1848, determined to follow the fortunes of the fallen dynasty, he abandoned practice, and resigned the offices he was so much attached to. This painful separation

was followed by domestic afflictions of the most poignant character, and lastly, by the ravages of a slow but painful disease. Amid his tribulation he was cheered by the sincere friendships he had known how to form in more prosperous days, and supported by the practice of a mild, tolerant and enlightened piety.

## MEDICAL NEWS.

**ROYAL COLLEGE OF SURGEONS.**—The following gentlemen, having undergone the necessary examinations for the diploma, were admitted members of the College at the meeting of the Court of Examiners on the 16th inst. :—

CALRY, J. W., Market Rasen, Lincoln.  
COLLYER, J., Playdon, Sussex.  
COUCH, W. O., Theberton-street, Islington.  
HARRIS, G. H., Army.  
HOLMES, W., Stoke Newington.  
HURDLE, G., Over Darwen, Lancashire.  
MALONE, J. G., Queenstown.  
ROSS, F. D., Tunbridge Wells.  
SMITH, T. P., Croydon.  
TAYLOR, C., Worcester.

Also, on the 19th inst. :—

DEARDEN, J., Accrington, Lancashire.  
EATON, J., Grantham.  
FURBER, G. H., Camden-road.  
GARNER, J., Birmingham.  
GRACE, H., Bristol.  
HAYWARD, H. H., Queen Anne-street, W.  
MOULD, G. W., Sudbury.  
SADLER, H. G., Wandsworth.  
STOKOE, P. H., Peckham Rye.  
VAWDREY, J. C., St. Agnes, Cornwall.  
WEAVER, F. P., Chester.  
WILLEY, J., Bristol.

The following name was omitted in the list of those who had passed the preliminary examination for the Fellowship :—  
HUMPHRY, CHARLES HENRY, Brighton.

**APOTHECARIES' HALL.**—Names of gentlemen who passed their examination in the science and practice of medicine, and received certificates to practise, on Thursday, April 15, 1858 :—

SMITH, THOMAS PARKER, Croydon, Surrey.  
STOKOE, PAUL HENRY.  
WILLIAMS, CHARLES, Gloucester.

**MARISCHAL COLLEGE AND UNIVERSITY, ABERDEEN.**—On the 13th inst., after the usual examinations, Medical degrees were conferred on the following alumni, viz. :—

The degree of M.D. on  
WILSON, JAMES, Aberdeenshire.  
And the degree of M.B. on  
LESLIE, JAMES, Aberdeenshire.  
LIGHTBOURNE, WILLIAM ASHBURN, Argyleshire.  
MCKILLIAM, ROBERT, Aberdeen.  
PATERSON, HENRY, Aberdeenshire.  
REID, SAMUEL, Aberdeenshire.  
REITH, ARCHIBALD, Aberdeen.

At the same time, GEORGE CARR, M.B., of this University, was promoted to the degree of M.D.

**UNIVERSITY AND KING'S COLLEGE, ABERDEEN, 15th April, 1858.**—The following gentlemen, after examination, had the degree of M.D. conferred on them :—

BRUCE, WILLIAM, Aberdeenshire.  
DIXON, FREDERICK B., Norwich.  
DRUMMOND, JAMES, Kincardineshire.  
DUNCAN, JOHN, Morayshire.  
HENDERSON, GEORGE, Banffshire.  
HOLMES, JOHN, Derbyshire.  
ROBERTS, CHARLES, Kent.

The following gentleman was admitted as M.B. :—  
GRANT, GEORGE, Banffshire.

## DEATHS.

**BATES.**—On the 10th inst., at his residence, Sudbury, Suffolk, D. N. Bates.

**BRACHET.**—M. Brachet, of Lyons, Professor of General Pathology in the School of Medicine and President of the Academy of Medicine of that city, has just died, aged about 70. He has published several well-known works, among which may be mentioned his treatises on "Acute Hydrocephalus," on "Convulsions of Children," on the "Ganglionic System," on "Lead Colic," on "Hysteria," and on "Hypochondriasis." He has left his valuable library to the School of Medicine, and his country seat, together with a considerable sum of money, for the endowment of an institution for the reception of decayed members of the Profession.

**BURCH.**—On the 7th inst., at Sandown, Isle of Wight, Samuel Joseph Burch, M.R.C.S. Eng. and L.S.A. 1840, resident Medical officer, London Hospital, aged 42.

**BUSCH.**—Wilhelm Heinrich Busch, the celebrated Professor of Midwifery and Director of the Lying-in Establishment at Berlin, has just died, exactly at the completion of his 69th year, and just as his friends were preparing to celebrate his 70th birthday.

**HANNATH.**—On the 19th inst., at Stamford, John Hannath, M.D., aged 60.

**HYDE.**—On the 18th inst., at Battersea, James Cockburn Hyde, aged 74.

**ESENBECK.**—The great naturalist, Nees von Esenbeck, who has long held the presidency of the Leopold-Caroline Academy, and whose labours enjoy a world-wide celebrity, has just died at Breslau, at the ripe age of 82. We shall shortly present some account of his career.

**JONES.**—On the 8th inst., at Carnarvon, N.W., William Jones, M.D., late of the 1st, or King's Dragoon Guards, aged 81.

**MORENO.**—On the 28th Dec. last, at Buenos Ayres, Dr. D. Manuel Moreno, many years resident in this country as Minister Plenipotentiary from the Republic of the United Provinces of the River Plate.

**PAGE.**—On the 12th inst., at Calne, Wilts, George Page, M.D., in the 76th year of his age.

**STEVENSON.**—On Feb. 21, at Calcutta, R. D. Stevenson, sixth son of the late Rev. David Stevenson, of Wilton, Roxburghshire.

**STEWART.**—At Liberton Manse, near Edinburgh, James G. Stewart, M.D., F.R.C.P.E., H.E.I.C.S., aged 33.

## APPOINTMENT.

**UNIVERSITY OF LONDON—EXAMINERSHIP IN CHEMISTRY.**—At a meeting of the Senate of this University on Wednesday, the 14th inst., Dr. Alfred S. Taylor, F.R.S., Lecturer on Chemistry at Guy's Hospital, was elected Examiner in Chemistry in place of Professor Brande, who has resigned.

**INOCULATION WITH THE MATTER OF SMALL-POX.**—At Moneygall Petty Sessions, a woman, named Catherine Tierney, residing at Busherstown, was recently charged with inoculating two children for small-pox. The case was clearly proved, but as it appeared that the *doctress* had acted through ignorance, and as she undertook to give up the practice for the future, she was sentenced only to an imprisonment of twenty-four hours in Parsonstown Bridewell.

**AUSCULTATION IN 1793.**—The Editor of the *Boston Medical and Surgical Journal* directs attention to the curious facts recorded in the "Memoirs of the American Academy of Arts and Sciences." Vol. ii. p. 1, 1793. That a celebrated practitioner of that day, Dr. Edward Augustus Holyoke, diagnosed, by the application of the ear to the chest, the fact of a communication of an abscess in the thoracic walls with the lung. "On applying my ear," says Dr. Holyoke, "I plainly heard a whizzing," etc. "This is not the first instance," the Editor continues, "in which the great discovery of Laennec was almost anticipated." Dr. Walshe has happily chosen as a

motto for his work on the Diseases of the Lungs, a quotation from R. Hook, written in 1705: "Who knows but that we may discover the works performed in the several offices and shops of a man's body by the sounds they make, and thereby discover what instrument and engine is out of order?" Had Dr. Holyoke thought of applying the knowledge he obtained in this case to the diagnosis of thoracic disease in general, his name would have come down to posterity as one of the most illustrious in the annals of Medicine.

**MORTALITY OF THE PAST QUARTER.**—In the last quarter, viz. the thirteen weeks that ended on Saturday, April 3, the deaths registered in London were 17,308, of which 8193 occurred under 20 years of age, 2149 in the period of life 20—40 years, 2874 at 40 and under 60, 3247 at 60 and under 80, and 767 at 80 years and upwards. The average annual rate of mortality at all ages for the first quarter of five years (1853-57) was 26 to 1000 persons living; in the quarter that has just terminated the annual mortality was nearly the same, namely, 25·6. The mean temperature of the quarter was 38°, which is but slightly below the average; but the mean weekly temperature was below it in seven weeks (five of which were consecutive) out of the thirteen. In the same quarter of 1855, the mean temperature of the air fell to 34·1°, and the deaths rose to 19,627, a number which, though the population was at that time less, exceeds the deaths in last quarter by 2319. In both periods pulmonary diseases were in the ascendant. The present return shows that 4440 deaths were referred to diseases of this character, exclusive of phthisis and whooping-cough, being rather more than 25 per cent. of the total number. The two most fatal epidemic diseases were whooping-cough and measles, the former numbering 767 in the quarter, the latter 714. The East districts contributed a larger proportion of the deaths from these two complaints than any other of the five great divisions. The southern division, or all that part of London which lies on the south side of the river, contains a population which exceeds that of the eastern, but which lives on an area seven times as great. The following are the deaths in the quarter from diseases of the dietetic order:—18 from want of necessities, besides 71 of children from want of breast-milk; 9 from purpura and scurvy; 30 from intemperance, besides 27 from delirium tremens. These last numbers do not include deaths from injuries received by persons when drunk.

**CARLISLE DISPENSARY.**—A new building has been erected, in length 44 feet, by a breadth of 28 feet 6 inches, and a height of 25 feet—there being storeys with rooms 11 feet high. The whole is in the Italian style of architecture, and has a very neat though plain substantial appearance. It is surmounted by the inscription—Carlisle Dispensary, 1857. On the ground floor are a consulting room, 18ft. by 14ft., a spacious waiting room for patients, 26ft. by 12ft., a surgery 8ft. by 11ft., and a private consulting room for the examination of patients, 10ft. by 11ft. The patients enter by a door at the end of the building, and obtain their medicine from the surgery, through a small window which communicates with the waiting-room. Ascending by a winding staircase, we find on the upper floor a commodious and neatly fitted up committee-room, 16ft. by 11ft. 2in. It is already furnished with table and chairs, and is decorated with a neat cornice. There is also a sitting-room, three bed-rooms, and a kitchen, the latter fitted up with an ample and complete kitchen range. The whole is lighted with gas and well supplied with water. There are two convenient yards situated behind the building, one for the use of the house and the other for the patients. The building has cost about £700. At a meeting of the supporters last week it appeared as to the charges made for medicine, that in 1818 they were £176 19s.; in 1819, £141 18s.; then going back nearly ten years; in 1832 they were £166 14s.; in 1833, £162 13s.; 1834, £100, and in 1842 no less than £165 2s.; whereas, they only cost £36 4s. 7d. last year. Mr. Waldie asked, How are we to explain the change? and the Dean replied, Why the system's altered. Doctors don't now give so much doctors' stuff. (Laughter.) The Dean in his speech said, "I may observe that I have just been reading a narrative of the dreadful siege of Cawnpore, and I must say that my estimate of the grandeur of the Medical profession has been greatly heightened by that perusal. It was a noble thing to find that Medical men, weak-handed as they were, exposed as they were with any of the soldiers to all the dangers of the field, were engaged from morning to night in

tending the sick and healing the wounds of those who had been struck down. It is a most touching narrative. We are much indebted here for the exertions of our Medical men on a more peaceful scene; they were most able and most diligent. I thought for a moment that Dr. Rae had said the patients were treated homœopathically, but though I have little faith in homœopathy, I have still less in the allopathic system, and I should feel inclined to estimate the value of a Medical man inversely by the quantity of medicine he gives."

**STATISTICS OF THE MEDICAL PROFESSION IN PRUSSIA.**—The latest of these that have been published relate to the year 1856. According to these, for a population of 17,397,009 souls, there were 4019 doctors in Medicine or Surgery, and 1786 *wundärzte* (a lower class of surgical practitioners)—total 5804. There were also 1510 apothecaries or druggists. This gives a medical practitioner to about every 2950 inhabitants, and an apothecary to about every 11,340. Berlin.—In 1856, with a population of about 433,000 (exclusive of 16,648 soldiery, and about 4231 individuals belonging to these) souls, there were 500 doctors, 81 *wundärzte*, 39 dentists, 38 apothecaries, 70 veterinary surgeons, 137 midwives, and 24 of a newly-created health assistants. This gave a doctor to every 866, a *wundärzte* to 5345, a midwife to 3160, and an apothecary to 11,394 inhabitants. As compared with former years there is an increase of doctors and midwives, and a diminution of *wundärzte* and apothecaries. Hospitals.—There were treated in the Charité Hospital, Berlin, during 1856, 10,344 patients (5680 males and 4664 females). Of this number 8249 were cured or relieved, 207 were discharged uncured, 1 left, 966 died, and 921 remained under treatment. This mortality—proportion of 9·3 per cent.—is more favourable than had been observed during the preceding 10 years, a fact attributable to the good state of public health during 1856, inasmuch as the general mortality of civilians was only 11,280 as compared with 12,627 deaths in 1855. Taking the whole of the public hospitals in Berlin, the number of patients treated during 1856 amounted to 15,837, and the deaths to 1654, i.e. a mortality of 10·4 per cent. Comparing the number of civilians in Berlin, and the deaths of civilians, it will be found that 1 of every 27·3 inhabitants was treated in Hospital; and 1 of every 6·8 deaths took place in Hospital. In 1855, 1 in every 25 was so treated, and 1 in every 5·6 deaths took place there.

**NOVEL APPLICATION OF PHOTOGRAPHY.**—M. Péroz, Professor of Chymistry at the Conservatoire des Arts at Métiers of Paris, has just published a most interesting discovery of his, by which photography may be applied to the ornamenting of silk stuffs. The bichromate of potash is a substance commonly used in photography, being extremely sensitive to light. If a piece of silk stuff impregnated with this salt be exposed to the rays of light penetrating through the fissures of the window-blinds in a closed room, the points where the stuff has received these rays of light will assume a peculiar reddish tint. Now, suppose a piece of medal or of strong paper to be cut out after a given pattern, and to be laid upon a piece of silk prepared as before; if exposed to the sun, or, better still, to simple daylight, the pattern will be reproduced in a few instants. The pale red which the parts acted upon by the light assume is so permanent that nothing can destroy it; nay, it will fix other colours, such as madder, campeachy, etc., just like a mordant, and in that case it will modify the colour of those substances in absorbing it. The experiment may be varied as follows:—Let a fern leaf be laid upon a piece of prepared silk and kept flat upon it by a pane of glass; then that part of the silk which is protected by the leaf will retain its original colour, while all the rest will receive the impression of light, as above described, forming the ground on which the figure of the leaf will appear in white, grey, or whatever other colour the silk may have had before the operation. The richest patterns may thus be obtained on plain silks, and at a comparatively small expense.

**NATURAL AND UNNATURAL MORTALITY.**—The Registrar-General for Scotland says—"When attention was first directed in this country to sanitary inquiries, the earlier writers on the subject were accustomed to speak of a death-rate of 2 per cent. (200 deaths in every ten thousand persons) as a low mean, from which they might calculate that all the

deaths below that mean might be ascribed to natural causes, but all those above it to unnatural or preventible causes, which might be removed by proper sanitary arrangements; and their efforts were to be directed to improve the general health of the community, in order that this low rate of 2 per cent. might be attained. Improved knowledge and further inquiries have elicited the fact, that certain rural districts exist in England where the mortality, as a mean, does not exceed 170 deaths per annum in every ten thousand living; and the fact that the mortality in all the rural districts of Scotland, as a mean of the last three years, only amounts to the proportion of 156 deaths in every ten thousand of the estimated population, not only justifies the Registrar-General of England in considering all the deaths above 170 in every ten thousand persons as unnatural deaths, but would warrant the reduction of the death-rate of what might be termed natural causes, to 150 deaths per annum in every ten thousand persons. We know, that, in the rural districts, where the above low rate of mortality prevails, a certain proportion of the deaths arose from causes which may be described as preventible, and which improved sanitary arrangements would remove; so that, in so far, at least, as Scotland is concerned, it would be fair to consider all the deaths above 150 in every ten thousand of the population ( $\frac{1}{4}$  per cent.) as unnatural deaths, which might be prevented were sanitary and other arrangements duly attended to. Had such been the death-rate over Scotland for the last three years, there would have been a saving, during that period, to the extent of 46,155 lives."

**ST. MARY'S HOSPITAL, MANCHESTER.**—We learn from an interesting lecture by Dr. Radford that this hospital was founded in 1790. "It had always been a dispensary, not only for the treatment of diseases of infants, but also for those of children. The noble building in which they were then assembled, raised to commemorate the visit of our most gracious Queen, had been intentionally and architecturally constructed to receive and relieve the sufferings of women and also those of her offspring. Provision was now made in St. Mary's Hospital for about fifty children. In cases where they are of tender age, and required their mother's care, they were admitted to take charge of and suckle them. In that hospital there was no limitation of age for the admission of females, but male children were not admitted after a certain age. It was now fully determined to open that institution for educational purposes. It was quite impossible to teach this department of medicine otherwise than by giving along with oral disquisition, practical instruction, and it was a matter of sincere gratulation to himself confidently to state that his colleagues had entered 'heart and hand' into this good cause; and he had the satisfaction to state that the lectures delivered in that hospital were now fully recognised by all the examining boards of the different universities and colleges of Great Britain and Ireland. The intended system of education would embrace full and complete courses of lectures on that branch of medicine treated there, combined with practical instruction. One important feature in the arrangements would be that clinical lectures would be regularly delivered." The lecturer then pointed out to students of medicine the advantage which would be offered to them by the proposed arrangement, and said that Dr. Clay would give the introductory lecture on the practice of that hospital on the 3rd of May, and Mr. H. Winterbottom would give his introductory lecture on the following day.

**THE MEDICAL CHARITIES ACT OF IRELAND.**—A deputation of Medical practitioners waited last week on Lord Naas, on the subject of the amended bill, in reference to the Medical Charities Act of Ireland, lately introduced into Parliament. The deputation consisted of Sir Henry Marsh, President of the College of Physicians, Hans Irvine, President of the College of Surgeons, and a number of presidents and secretaries of the associations. Dr. Mackessy opened the proceedings by entering into the clauses of the bill, which are pronounced by the Profession to be objectionable. The clause appointing non-Medical for the present Medical inspectors was dwelt on at great length, and resolutions from the Colleges of Physicians and Surgeons disapproving of it were read, and a universal feeling expressed of its being not only unjust to the destitute poor and to the ratepayers, but to the Medical profession. The other questions—a minimum salary of £100 per annum for poor-law Medical officers—the

necessity of cancelling tickets got by persons in comfortable circumstances, were, with other important matters, alluded to. Lord Naas observed that he considered the second and third clauses of the bill deserving special consideration, and he therefore sought the opinion of the gentlemen on the question of substituting the poor rates as a source of pecuniary support for the infirmaries as contemplated in these clauses. A unanimous feeling was expressed condemnatory of such a substitution, and several instances were shown, that the class of persons receiving infirmity relief would shrink from becoming inmates of a poor-house Hospital under any circumstances; and, further, that such a change would tend to a demoralizing effect. With these views Lord Naas seemed to concur.

**TOWN AND COUNTRY MORTALITY.**—According to the last return of the Registrar-General for Scotland, it appears that wherever masses of human beings are crowded together, there it would appear that the rate of mortality is proportionally higher. This not only appears by contrasting the deaths in the manufacturing and mining counties with those in which the greater part of the population is engaged in agricultural pursuits, but is more strikingly manifested, by dividing the population of Scotland into residents in the towns, and dwellers in the country. Thus, during the year 1857, in the 129 town districts, which include the half of the Scottish population at the taking of the census in 1851, there were registered 38,436 deaths; whilst, in the 866 rural districts, with an equal population, the registered deaths only amounted to 23,489—thus showing an excess of deaths in the town districts to the extent of 14,947. In other words, the inhabitants of the towns were cut off during the year in the proportion of 244 deaths in every ten thousand persons, or 1 death in every 41 persons; whereas, in the rural districts, the proportion was 157 deaths in every ten thousand, or 1 death in every 63 persons living.

## VITAL STATISTICS OF LONDON.

Week ending Saturday, April 17, 1858.

### BIRTHS.

Births of Boys, 1009; Girls, 956; Total, 1965.  
Average of 10 corresponding weeks, 1848-57, 1583.

### DEATHS.

	Males.	Females	Total.
Deaths during the week ... ..	681	576	1207
Average of the ten years 1848-57 ... ..	566.6	535.0	1101
Average corrected to increased population ... ..	...	..	1212
Deaths of people above 90 ... ..	...	2	2
Deaths in 15 General Hospitals ... ..	36	17	53

Amount of horizontal movement of air in the week ... ..	320 miles

## TO CORRESPONDENTS.

If Students would make some of the experiments he suggests, he might render good service to medicine.

*W. S. S.*—Barlow's Manual, or Aitken's Handbook.

*Fair-play.*—The horse does not kick every cur which runs yelping at his heels.

*Mr. Windsor's* translation of Gräfe's paper shall appear entire; but it had better be deferred until after the professor's own reply to Dr. Mackenzie and Mr. Jones.

*Mr. Haviland's* letter arrived too late for the subject to be treated this week.

*Professor A. von Gräfe's* reply to Dr. Mackenzie and Mr. Wharton Jones shall appear next week if possible.

*Dr. Bence Jones's* paper "on sugar as an article of diet in Diabetes Mellitus" shall appear next week.

*Dr. Cotton, King's Lynn.*—We wish to avoid comments on the management of other journals. Had a full report of the College Festival been sent to this journal by the Council, it would, in all probability, have received immediate insertion.

*J. F. S.*—No objection whatever—quite the reverse.

*Mr. Houghton.*—As soon as possible, but there are several papers in type which must appear previously.

*Dr. Steel.*—Next week.

*Juvenis* informs us that in the year 1820 Dr. Wood practised revaccination in the second week of hooping-cough with the best results. Perhaps he will refer us to Dr. Wood's paper on the subject. Our correspondent also desires to know "if the health of our towns would be improved, if instead of burning our dead, the *Egyptian plan* were practised in this country, of depriving the bodies of all moisture by exposing them to the heat of public ovens for some hours, by which the bodies may be reduced to a few pounds only."

#### DOUBTFUL STATEMENTS OF PATIENTS.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—Your correspondent "T. J. W." reminds me of that description of warrior who can only fight behind stone walls, and shows the tenor of his mind by quoting a vulgar proverb in his strictures upon a case of aneurism reported in your previous number. For I am at a loss to imagine what connexion there can be between a bird fouling its own nest, and a faithful history of an interesting surgical disease, in the details of which none but a mind woefully perverted from the standard of right could find anything to reflect upon one's Professional brethren. I am, &c.

Sussex County Hospital, April 20, 1858.

FRED. JOWERS.

#### CHLORODYNE.

TO THE EDITOR OF THE MEDICAL TIMES AND GAZETTE.

SIR,—In reply to your correspondent "Chemicus," I beg to observe that chlorodyne does unquestionably contain an alkaloid, which, to my knowledge, is quite new in therapeutics, and, if necessary, I am quite willing to substantiate this statement (as suggested by "Chemicus") before any tribunal; consequently your correspondent's statement is at variance with truth, and if any credence is attached thereto, it will most assuredly mislead and disappoint.

"Chemicus" is also in error in attributing my denial of the correctness of the various analyses to any slight equivocation, such as sugar or treacle. I assert again, most positively, it is not the case. The active principle is the foundation for my denial, and without that all the various analyses of chlorodyne will fail to produce the remarkable physical or medicinal effects which the Profession so willingly and justly attribute to the genuine chlorodyne.

Your correspondent is likewise wrong in presuming that I attach importance to the physical appearance of chlorodyne; a careful perusal of my letter in your journal of April 10th, will readily convince any impartial reader that its therapeutic action is mainly referred to. I coincide with "Chemicus" in regretting that the Government of this country has not provided an authority to arbitrate and recompense the authors of valuable discoveries, likewise to expose and punish misrepresentations. The universal acknowledgments of the merits of chlorodyne would have obtained the former, whereas the misrepresentations of "Chemicus" would have justly claimed the latter, as such statements as his tend to increase the misfortune of the afflicted, and cause great dishonesty with those who prepare and vend the fictitious compound.

I regret that "Chemicus" deems it necessary to withhold his name; his cause must be weak indeed to require such unmanly protection. I would further observe that in future anonymous communications will be unnoted.

I am, &c.

J. T. DAVENPORT.

33, Great Russell-street, Bloomsbury,  
April 21st, 1858.

#### MEDICAL EPITAPHS.

A prolonged medical statement of the disease of which the departed may chance to have died is extremely popular. At Acton, in Cornwall, there is this account of how one Mr. Morton came by his end:—

"Here lies entombed one Roger Morton,  
Whose sudden death was early brought on;  
Trying one day his corn to mow off,  
The razor slipped and cut his toe off:  
The toe, or rather what it grew to,  
An inflammation quickly flew to:  
The parts they took to mortifying,  
And poor dear Roger took to dying."

And here is a still more entertaining one, upon a certain lady in Devonshire; singularly free from any nonsensical pretence or idle bravado:—

"Here lies Betsey Cruden,  
"They woud a leaf'd but she cooden,  
'Twas na grief na sorrow as made she decay,  
But this bad leg as cam'd she away."

Whenever I read (and it is often) of folks who were passionately desirous to leave this vale of tears, I shake my head, and quote the simple-minded Betty: "For all this," says I, "they woud a leaf'd, but they cooden."

There is a distressing inaccuracy of metaphor in the following south country elegy, but the meaning is painfully distinct:—

"Here lies two babes as dead as nits,  
They was cut off by ague fits."

A doctor of divinity, who lies in the neighbourhood of Oxford, has his complaint stated for him with unusual brevity, as well as his place of interment:—

"He died of a quinsy,  
And was buried at Binsy."

To complete these medical extracts, I may quote this warning cyprus-flower, culled from a Cheltenham cemetery:—

"Here lies I and my three daughters,  
Killed by a drinking of the Cheltenham waters;  
If we had stuck to Epsom salts,  
We'd not been a lying in these here vaults."

COMMUNICATIONS have been received from  
Dr. SYMONDS, Clifton; Dr. FYFE, Aberdeen; Dr. MARION SIMS, New York; Mr. P. HEWITT; Dr. OGILVIE, Aberdeen; PROFESSOR A. VON GRAFE, Berlin; Dr. STEEL, Carlisle; SECRETARY, GENERAL BOARD OF HEALTH; Mr. RIVERS; Dr. RYAN; Mr. COLLET; Mr. FOX; Dr. HILDIGE; Mr. MARSTON; Dr. F. ADAMS, Aberdeen; REGISTRAR GENERAL; Dr. MAYR, Dr. POLITZER, and Dr. SCHULLER, Vienna; Mr. J. EARLE; Mr. C. J. EVANS; Dr. FOWKE; Mr. T. MARTIN; Mr. J. CLARKE; Mr. W. HUNT; Mr. F. KEMP; Mr. BINGHAM; Mr. GREEN; MEDICUS; Dr. BENICE JONES; Mr. WINDSOR, Manchester; Mr. ADAMS; Mr. DICKINSON; Mr. YARNOLD; Mr. MILL; Mr. TALBOT; Mr. McDERMOTT; Mr. WRIGHT; Mr. HAVILAND; Dr. SEMPLE.

## APPOINTMENTS FOR THE WEEK.

April 24. Saturday (this day).

Operations at St. Bartholomew's, 1½ p.m.; St. Thomas's, 1 p.m.; King's 2 p.m.; Charing-Cross, 1 p.m.

ROYAL COLLEGE OF SURGEONS, 4 p.m.: Professor Quekett, "On the Vertebrata."

MEDICAL SOCIETY OF LONDON, 8 p.m.: A. Poland, Esq., "On the Recent Improvements in Ophthalmic Practice by a more cautious Administration of the Drug Mercury."

ROYAL INSTITUTION, 3 p.m.: Edwin Lancaster, M.D., F.R.S., F.L.S., "On the Vegetable Kingdom in its Relations to the Life of Man."

### 26. Monday.

## EXPECTED OPERATIONS.

King's College Hospital.—The following operations will take place this day (Saturday), at 2 o'clock:—

Talipes varus; recto-vaginal fistula. By Mr. Fergusson. Removal of necrosed bone from os calcis. By Mr. Bowman.

Westminster Hospital.—The following operations will take place on Tuesday next, at 2 o'clock:—

Removal of necrosed bones of the foot. By Mr. Holt.

St. Mary's Hospital.—The following operation will take place on Wednesday (the 28th), at 1 o'clock:—

Vesico-vaginal fistula. By Mr. J. B. Brown.

## LECTURES

ON

THE ANATOMY, INJURIES, AND DISEASES  
OF THE HEAD,

DELIVERED IN THE

Theatre of the Royal College of Surgeons of England.

By PRESCOTT HEWETT,

Professor of Anatomy and Surgery to the College.

## ON FRACTURES OF THE SKULL.

LECTURE III.—*Concluded.*

## ON INDIRECT FRACTURES OF THE BASE OF THE SKULL.

A fracture at the base may manifest itself by an escape of blood into the cellular tissue of the orbit and eyelids; by bleeding at the nose, or subsequent vomiting of blood; by bleeding from the ears; by an escape of blood into the cellular tissue in the mastoid region, or into that of the back of the head.

The blood effused into the orbits may be either venous or arterial; the former, however, is by far the more common of the two. The anatomical relations of the back of the orbit with the large venous channels in its immediate neighbourhood, as well as the close connexion of the bones with the ophthalmic artery, will at once give us the sources from whence the blood is derived.

A fracture involving the orbital plates of the frontal bone, and extending into the sphenoid, may implicate either of these sets of vessels.

The blood, at first poured out at the back of the orbit, soon makes its way forward: readily infiltrating the loose cellular tissue of this region, it first shows itself under the ocular conjunctiva, and subsequently spreads into the eyelids.

We have, then, generally to deal with blood in the eyelids, and blood under the ocular conjunctiva. Now that in the eyelids is only of use to us in as far as it co-exists with an effusion under the ocular conjunctiva. It is then the blood effused in this situation which becomes the one important point. In attempting, therefore, to draw our diagnosis, let us not forget the exact course which the blood must of necessity take, if it comes from the back of the orbit; and bear in mind that we ought not to be able to trace the limits of this subconjunctival effusion: *a few patches here and there are of no value.*

A blow on the forehead, or on the temple, or on the cheek, may give rise to infiltration of blood in the eyelids, the ocular conjunctiva remaining clear all the while. It is at once evident, under these circumstances, that the blood in the lids cannot have proceeded from the vessels at the base of the skull. There may even be a few coloured patches of blood under the ocular conjunctiva, and yet the evidence will be the same, so long as the effusion is limited to the subconjunctival cellular tissue at the front part of the eyeball.

To be of any value as a diagnostic sign, the extravasated blood observed about the front part of the eyeball must extend into the cellular tissue of the orbit beyond our sight.

It is, then, as I have already said, the effusion of blood under the ocular conjunctiva which must serve us as a guide in our diagnosis.

The roof of the orbit may be extensively broken—this injury may or may not be accompanied by bruising of the eyelids—there may be an effusion of blood at the back of the orbit, and yet, so long as the ocular conjunctiva remains clear, we have really no means of getting at the true nature of the accident.

In analysing twenty-three cases of fractured base of the skull, involving more or less extensively the orbital plates of the frontal bone, all of which occurred at St. George's Hospital within the space of ten years, I find that, in eight cases, there were no traces of extravasated blood to be seen either in the eyelids or under the ocular conjunctiva, and that, in five cases, the effusion of blood occupied the eyelids only, so

that in these thirteen cases there could have been no suspicion whatsoever as to the existence of a fracture. But, on the other hand, the nature of the accident was most clearly revealed in the remaining ten cases by an effusion of blood which occupied both the ocular conjunctiva and the eyelids.

If the patient be seen at a very early period after the accident, or if the effused blood be in small quantity, it may be altogether confined to the subconjunctival cellular tissue of the eyeball, where it first becomes visible; but this I have only seen in a very few instances; in the majority of cases which have fallen under my notice, the blood has been effused in the eyelids as well as upon the eyeball. I cannot, however, quite agree with M. Velpeau in thinking that the lower lid always becomes discoloured before the upper one: that the blood does most frequently gravitate into the lower lid there is no doubt, but I have several times seen the upper lid and subconjunctival cellular tissue of the eyeball ecchymosed, without any discoloration of the lower lid.

So great sometimes is the effusion of blood into the orbit, that the eyeball is protruded from its socket: whenever this happens it always indicates that the fracture is most extensive. Protrusion of the eyeball from extensive effusion of blood into the orbit occurred in three out of the ten cases to which I have alluded.

I have been led thus to dwell at some length upon the state of the ocular conjunctiva in these cases, as, from all I have seen, I feel convinced that many errors in diagnosis are committed for want of a little care in examining the exact state of this tissue before we express an opinion as to the existence or non-existence of a fracture of the base.

These remarks, will, I think, be most aptly illustrated by a case which fell under my notice some time back.

A man met with a severe injury of the head, which was followed by ecchymosis of the eyelids, and of the ocular conjunctiva, with marked protrusion of the eyeball. The case was pointed out to me as one in which the signs of fractured base, involving the bones of the orbit, were clearly marked, and such indeed had been the diagnosis given of this case. But, on separating the bruised eyelids widely from each other, I perceived that the effusion under the ocular conjunctiva consisted merely in some small patches of blood in the immediate neighbourhood of the cornea; and, as I could distinctly see that all the remaining part of the cellular tissue covering the eyeball was perfectly clear, I at once expressed my doubts as to the correctness of the diagnosis. 'The man died in a few days. No trace of fracture was detected at the base of the skull, and the cellular tissue of the orbit was free from blood. There was nothing in the condition of the orbit to account for the protrusion of the eyeball.

In this case it is evident that with a little more care the error in diagnosis might have been avoided.

Some cases will, however, baffle the most attentive Surgeon. Now and then, but very rarely as far as my own experience goes, a case is met with, in which there is extensive effusion of blood in the eyelids and in the orbit, pushing forwards the eyeball, without any fracture at the base. A case of this kind, which happened some few years back at St. George's Hospital, has been reported by Mr. Timothy Holmes.

A gentleman having been thrown from his horse, was admitted into St. George's Hospital shortly afterwards, in a state of complete insensibility. Over the left eye were two very small wounds, one of which led down to roughened bone. The left orbit was full of blood, the eyeball pushed forwards, and the lids very tense. On opening the lids the ocular conjunctiva was seen to be full, but not chemosed. The next day the ecchymosis in the orbit had increased. The patient died on the fourth day after the accident. No trace of fracture could be discovered about the base of the skull, but there was a fracture separating the angular process of the malar from the frontal bone, and displacing it slightly inwards; and it was from this spot that the blood had got into the orbit. A linear fissure was also found extending through the orbital process of the malar bone to the suture between it and the sphenoid.

Thus far, I have spoken only of the extravasation of venous blood into the orbit; but the effusion of arterial blood into this region presents even further interest, in as much as it may lead to the formation of a traumatic aneurism, which may go on increasing in size, and thus imperatively call for surgical interference.

(a) In the year 1834, a boy, who had fallen into a ship's hold, was admitted into the London Hospital, under the care of the late Mr. Scott, with concussion of the brain. On the right side of the head there was a violent contusion, with a good deal of swelling; there was also protrusion of the right eye, which was fixed and motionless; the pupil was dilated, and vision was lost. There were no symptoms of cerebral pressure. He gradually recovered from the concussion of the brain, but the eye became more and more prominent. The protrusion of the globe immediately after the accident, without symptoms of cerebral compression, proved that it arose from extravasated blood within the orbit; and the further continued protrusion rendered it probable that the aperture in the vessel from which the blood escaped had not closed. As the globe became more prominent, pulsation was felt on pressure; and, when the lids were separated, the eye could be distinctly seen to be propelled forward, at each stroke of the heart. Pressure was made on the globe; but, after being borne for two days, it occasioned so much pain that it was removed. Five weeks after the accident, a profuse arterial hæmorrhage occurred from the nose, just after examination of the eye. Mr. Scott commanded the bleeding by pressure on the right common carotid artery, and immediately secured that vessel by placing a ligature around it. The protruded globe at once receded to a great degree. The operation had the desired effect. The prominence of the eye gradually diminished, and the lad was ultimately cured.

In the year 1835 (b), a seaman, aged 20, was admitted into the Seaman's Hospital, under the care of Mr. Busk, with the usual symptoms of severe concussion of the brain, accompanied by considerable bleeding from the right ear, and some tumefaction over the right temple. There was also a small lacerated wound behind the left ear. It was stated that he had received from the gaff of the vessel to which he belonged a severe blow on the right side of the head, by which he was immediately rendered insensible. The bleeding from the right ear continued all night. The next day he was quite sensible, did not complain of any pain, but appeared dull. On the day following he was still very dull, and it was found that he was quite deaf on the right side. The condition of the right eye presented nothing abnormal; but the eyelids and integuments about the left eye were swollen from serous effusion, its pupil was closed and fixed, and he was unable to move the globe of it in any direction. There was also paralysis of the facial muscles on the left side. On the eleventh day after the accident he complained, for the first time, of an uncomfortable numbness in the left side of the face, and a sensation of dryness about the mouth, which was, however, as moist as possible. Some purulent discharge was observed about the right meatus. On the twelfth day, the integument of the face and nose, and the scalp nearly to the vertex, on the left side, was exceedingly tender to the touch, but without the slightest morbid appearance. The eye itself was in the same condition as before. Subsequently the left eye became inflamed from constant exposure, consequent upon the facial paralysis; the lower half of the cornea became nebulous, suppurated, and ulcerated. About six months after the accident Mr. Busk perceived, for the first time, a distinct pulsation of the eyeball, and a firm pulsating tumour in the upper and inner part of the orbit, immediately within the superciliary ridge, and about half an inch in length in its transverse and longest diameter. This tumour appeared to be situated between the levator of the eyelid and the bone, and was not evident externally; but when the eyelid was raised, it caused some projection of the loose conjunctiva. A distinct thrill was present, as well as a very loud whizzing sound, which, by means of the stethoscope, was heard over the inner canthus of the right eye, and on the left side of the frontal bone, as high as the roots of the hair, and nearly as far back as the ear. The eye felt hot and uneasy, but otherwise there was no pain, and the patient complained principally of very loud noises in the head. Having ascertained that pressure on the left common carotid artery put a stop to the various symptoms above alluded to, Mr. Busk applied a ligature to that vessel. Everything went on well for a few hours after the operation, and then obscure pulsation reappeared in the tumour. But this pulsation gradually subsided again, and on the second day no remains of the tumour could

be felt, and all pulsation was gone from the orbit, nor could any sound be heard by means of the stethoscope. The prominence of the eye became less and less, the paralysis of the left side of the face and of the muscles of the eye remained complete; but sensation was perfect, except on the left side of the nose. When discharged from the Hospital, this patient was much in the same condition. He was again seen by Mr. Busk a long time after the operation, and no recurrence of the disease had taken place.

In the year 1854 (c), a man, aged 49, was admitted into the London Hospital, under the care of Mr. Curling, with considerable bleeding from the right ear, and labouring under symptoms of concussion. Having fallen from a height of seven feet, it appeared that he had pitched on his right shoulder and right side of the head. The bleeding from the ear was followed by a serous discharge, which continued for about a week. Total deafness of the right ear was also present, and he complained of a dull, aching pain on the right side of the head. About five weeks after the accident, some slight inflammation and chemosis were, for the first time, observed about the right eye. The eye itself became prominent, and, at length, protruded so much that a careful examination of the orbit was made. This led to the detection of a pulsation in the upper lid, with a very distinct bruit upon placing the ear against the patient's right temple. Finding that the eye was becoming more and more prominent, that vision was impaired, and that there was very little power of moving the eye, Mr. Curling tied the right common carotid artery. All pulsation in the orbit ceased at once, and the other symptoms about the head were relieved. The eye gradually subsided into its proper place; the power of moving the eyeball returned, with partial restoration of sight, in the course of time.

Here, then, are three cases in which a pulsating tumour formed within the orbit after a severe injury of the head. In every one of these three cases, the formation of the tumour was distinctly connected with the accident; in all, the aneurismal character was clearly made out; and, in all, a ligature placed on the common carotid at once put an end to the symptoms. Viewed in connexion with injuries of the head, these cases are certainly most valuable, and so, too, are they most valuable, as additions to the other numerous cases already on record in which the tying of the common trunk of an artery for a traumatic aneurism of one of its branches, has proved perfectly successful.

But to return to our own immediate subject. Bleeding from the nose or mouth, or vomiting of blood, you will find not unfrequently occurring after injuries of the head; but the great vascularity of the membrane lining these cavities renders this bleeding much less valuable as a diagnostic sign of fractures of the base, than that which proceeds from the ear. Still, bear in mind that if the bleeding be copious, and especially if it continue for some time, there is no doubt that this symptom may also become one of great value. In the vomiting of blood it not unfrequently happens that the fluid thrown up is of a dark, bistre colour; having been swallowed and retained in the stomach for some time, the blood has, in fact, been more or less acted upon by the gastric juice. Such appearances I have several times noticed, when vomiting took place after the subsidence of the symptoms of concussion which accompanied these accidents. In 32 cases of fractured base, implicating the central bones of this region, all of which occurred at St. George's Hospital within the space of ten years, bleeding from the nose or mouth, or subsequent vomiting of blood occurred in no less than in 14 instances. These symptoms in these cases were such as to lead to the belief that a fracture existed in some of the bones of the base corresponding to the nose or mouth, and dissection proved that in the 14 cases, the fracture was in 4 confined to the ethmoid bone, in 3 to the body of the sphenoid, and in 1 to the basilar process; that in 5 cases the fracture involved both the ethmoid and the sphenoid, and, in 1 case, that the fracture extended not only through these two bones, but through the basilar also.

Bleeding from the ears in severe injuries of the head has, for many years past, been held, and deservedly so too, as one of the most valuable diagnostic signs of fractured base. In testing the value of this sign you will not be called upon, as you were about the nasal and pharyngeal cavities, to take into consideration the great vascularity of the membranes

(a) Med. Chir. Trans. vol. xxii. p. 134.

(b) Med. Chir. Trans. vol. xxii. p. 124.

(c) Med. Chir. Trans. xxxvi. 221.

lining the cavities of the ear. The vessels belonging to these membranes are so small, and so few in number, that they cannot give rise to bleeding of any importance. Slight bleeding, it is true, might be produced from the ear itself, but slight bleeding is assuredly not sufficient to warrant any Surgeon in giving an opinion as to a fractured base. The bleeding, to be of any value to us as Surgeons, must then be of a serious nature; but this is not all, it must also, and mark this especially, continue for some time; and if, in addition to these points, you can also ascertain that the membrana tympani has been recently ruptured, you need no longer hesitate; and, let the issue of such a case be what it may, you can state with confidence that there is a fracture of the base running through the petrous bone, and opening up a communication between the cavity of the tympanum and some of the numerous and large vascular channels which surround this bone, or with an extravasation of blood within the cranium itself. Such is the result of the experience of all those who have paid much attention to this subject, and such, too, are the results of my own experience, derived from a close inspection of many cases of this nature, both in the wards and in the dead-house of St. George's Hospital.

In thirty-two carefully-dissected cases of fracture of the middle fossa implicating the petrous bone, the tympanum was thus laid open, and its membrane ruptured in fifteen, or very nearly one-half. The flow of blood in most of these cases was profuse and continuous, and in all the diagnosis of the injury was clear.

Fractures of the temporal bone, however, frequently occur, in which there is no sign that can lead to the supposition of such an injury. In such cases either the line of fracture does not extend into the tympanum, or, if it does, the membrane is not ruptured, and the blood cannot consequently get into the external meatus. Thus, in twelve of the seventeen remaining cases, the tympanum was not involved in the fracture, and in the other five cases the tympanum was fractured, but the membrana tympani was not ruptured.

Here again then we have, as we have already had, both in the orbital and in the nasal and pharyngeal regions, many cases, more than one half, in which there were no indications which could be relied on, as to a fracture of the base. Better, in such cases, to abstain altogether from giving an opinion. In doing thus, we may, it is true, be told that many a fracture has been found when not anticipated; but on the other hand, we shall not be reproached with frequent examples of the presumed existence of a fracture being disproved on examination after death.

Just now I alluded to the possibility of the petrous bone being broken, so as to communicate with one of the venous sinuses on the inside of the skull, and that without any rupture of the membrana tympani. It is evident that in such cases there can be no bleeding from the ear; but the blood poured into the cavity of the tympanum will soon find its way out through the Eustachian tube, so that we may have bleeding either from the nose or from the mouth, or subsequent vomiting of blood. You will find a few cases of this kind already placed on record, cases in which a careful dissection has clearly revealed the peculiarity of the injury.

And this passing of blood from the cavity of the tympanum through the Eustachian tube may even take place when there is a rupture of the membrana tympani; so that, in some few cases of fractured petrous bone, we may actually have bleeding both from the ear and from the nose at the same time. Of this you will find the following well-marked example in J. L. Petit.

A man (d) fell on to the back of his head; he was picked up perfectly insensible, and in this state he remained until the day of his death. On the second day after the accident, a large quantity of blood was observed oozing from both his ears, and a small quantity of blood also came from his mouth. At the examination of the head an extensive fracture was found separating the squamous from the petrous portions of the temporal bones, and the cavity of the tympanum on both sides was filled with blood. Some of the blood had escaped from the ears, through a rupture of the membrane of the tympanum, and some had also passed through the Eustachian tube, and this found its way into the mouth.

And now, as an illustration of the precision with which you may actually trace out the exact course of an extensive frac-

ture of the base, I shall mention one example which fell under my notice a few years ago. I might select several other cases from those which I have by me, but I prefer taking this single one, as it illustrates the various points to which I have alluded thus far.

A man, aged 65, having been knocked down by a mail-cart, was admitted into St. George's Hospital, under the care of Mr. Keate, with severe contusion of the scalp on the left side of the forehead, and a small wound exposing the bone in the neighbourhood of the left superciliary ridge, but no fracture could be detected at this spot. The eyelids were closed by the effused blood, and there was profuse hæmorrhage both from the nose, and from the right ear. The collapse was extreme, with perfect insensibility, and the mouth was drawn to the left side. On the following day the bleeding from the ear continued, and, moreover, blood was detected extensively infiltrated into the cellular tissue of the orbit.

Here, then, were well-marked signs of a fracture starting from the spot which had been first struck, the left side of the forehead, and stretching across the roof of the orbit, across the roof of the nostrils, and into the right petrous bone. With such signs could there be any hesitation? There was none—and such was the diagnosis which was confidently given.

The man lived eleven days in a semi-comatose state. The bleeding from the ear, which gradually diminished, was followed by the discharge of a watery fluid, which continued up to the time of this man's death. A line of fracture was traced from the left frontal, through the orbital plate, across the æthmoid, and body of the sphenoid, into the right petrous bone, along the anterior surface of which it ran from the apex to the base, passing in the line of the bottom of the meatus internus. The cavity of the tympanum was laid open, and the membrana tympani was ruptured.

## ORIGINAL COMMUNICATIONS.

### SOME REMARKS ON

## SUGAR AS AN ARTICLE OF DIET IN DIABETES MELLITUS.

By H. BENCE JONES, M.D. F.R.S.

Physician to St. George's Hospital.

In the *Comptes Rendus* for January 26, 1857, p. 133, and also in the *Gazette Hebdomadaire* 1857, p. 115, there are some observations by M. Piorry on a diabetic patient of his in the Charité Hospital, to whom he gave 125 grammes, or about 4 ounces of sugar-candy daily, at the same time he insisted on absolute abstinence from all drink, and from liquid food, and he gave a double portion of meat. From the short notice published it appears that this treatment was continued twelve days, during which only 135 grammes (or about 4½ ounces) of sugar were passed daily, while before this treatment 700 grammes (about 22½ ounces) of sugar were lost, by passing off through the kidneys, in 24 hours. The urine fell in quantity from 10 litres (17½ pints) to 2½ litres (4½ pints nearly). M. Piorry concludes that this experiment confirms his ideas as to the advantage of supplying the sugar that is lost in diabetes. It also shows, he says, that abstinence from drink is of extreme importance.

In the *British Medical Journal* for November 14, 1857, there is a report of a paper read by Dr. Budd, September 24, 1857, and March 13, 1858, a sequel is given, on a case of diabetes, in which for nearly ten months sugar-candy, varying in amount from 16 to 6 ounces daily, with the addition sometimes of 4 ounces of treacle, or 6 ounces of honey, were taken. The patient was considered by Dr. Budd to improve greatly in consequence of this plan of treatment. Throughout the case no analysis was made of the amount of sugar. The specific gravity and quantity of the urine are occasionally given, and in the first two months the increase of weight is stated as being nearly 20 pounds.

Dr. Budd mentions a case of Dr. Brittan's, in which from 6 to 12 ounces of sugar were given with honey for twelve days, and the urine decreased in quantity and specific gravity.

In the *British Medical Journal* Dr. G. Corfe records a case

in which a very much smaller amount of sugar was given (1 ounce of sugar and 1 ounce of honey daily), as he considers with advantage.

In the same Journal for December 19, 1857, Dr. Williams of Swansea mentions that he gave sugar, bread, and malt liquor according to Dr. Budd's proposition with the most unsatisfactory result in two cases.

I have reason to think that lately other Medical men have followed Dr. Budd's suggestion, and allowed their diabetic patients the freest use of sugar with or without bread. I have had patients consulting me in consequence of the great increase of all the symptoms of the disease, the thirst, the craving, the quantity of urine, and the wasting. Such cases might well be set down in opposition to the case recorded by Dr. Budd. But in a chemical complaint evidence may be obtained of the effect of any one article of diet much more decisive than the general result. For the general result depends on a multitude of causes, some of which may act in opposite directions. So that good might be attributed to that cause which really only made the other causes less beneficial.

It is sufficient answer to Dr. Budd to say that a bad general result was obtained in other cases of diabetes, but a more definite answer ought to be given in this disease than is possible in most diseases, and by the help of chemistry the action of the sugar ought to be exactly determined. If it be found that bread and sugar do increase the amount of saccharine matter in the urine, so as to leave no doubt on this point, then if improvement should occur when such substances are freely taken, the good must result from some other cause, which has not been well estimated. Bread and sugar are hardly, I suppose, considered by any one as the cause of diabetes, and though their effect may be accurately determined in this disease, yet the prime cause, whether it be the defect of chemical action, or the excess of nervous irritation, is still unknown, and variations in the action of this prime cause may produce much more remarkable effects on the urine than variations in the amount of starch or sugar taken as food.

I should have left Dr. Budd's general results to be answered by Dr. Williams and by others, but as harm is being done, and some of the results have long since been obtained by me, I have thought it well to submit them to the Medical Profession.

E. C., aged 12, was admitted 1854 into St. George's Hospital. She was said to have been ill six weeks, with pains in the bowels, wasting, thirst, excess of urine, sp. gr. 1042, and ravenous appetite; drinking quarts of water, and eating as much bread as she could get.

After three days of animal diet only she passed 3 pints of urine, specific gravity 1032, containing some sugar. In six weeks time the urine was reduced to 2½ pints, sp. gr. 1012, and containing no sugar. She had not gained in weight above one pound.

A very little bread was then given. The next day the water was 3 pints; sp. gr. 1016, and contained sugar. The bread was continued the next day, and then there was sugar. The following day no bread was taken, and there was no sugar. For three days bread was again taken, and sugar appeared; the following three days no bread was allowed, and the sugar disappeared. Again the bread was given in small quantity and the sugar reappeared, and when omitted disappeared. The bread was then finally omitted. Two pints of milk extra were given, and no sugar appeared the following day; the urine had a sp. gr. 1012, with no sugar. Potatoes were then given, and the next day the sp. gr. was 1019, and much sugar was present. The potatoes were stopped, and a pint and a-half of porter was given, and no sugar appeared. This was continued for ten days, and still no sugar was present in the urine.

Two ounces of lump sugar were then given. The urine had a sp. gr. of 1012. No sugar appeared in the urine. This was continued four days, and no sugar occurring, a small quantity of bread was also given. The sp. gr. rose from 1009 to 1022, and much sugar appeared. The bread was omitted, and an ounce of honey was given daily for a week, no sugar appearing; two ounces of honey were given, and no sugar appearing some bread was given, the sp. gr. rose from 1010 to 1030, and much sugar was present. The honey was continued without bread, and some sugar was found in the urine.

As it was desirable to determine more accurately the amount of sugar produced in the urine by the bread, I

examined the water by means of Soleil's saccharometer; 1st, when some bread was taken; 2ndly, when no bread was taken; 3rdly, when the third of a pound of lump sugar was taken and no bread; 4thly, when the sixth of a pound was taken. Then when the sugar was omitted. After this porter was given, and the effect on the urine determined. Lastly, a minimum quantity of bread was given. The following table gives the results of the experiments.

Diet.	sp. gr. of urine.	amount of sugar in urine.
June 30, animal diet only.	1014	none.
July 1, " "	—	none.
2, animal, with bread.	1025	19 grs. to each oz.
3, animal only	1003	no trace.
4, " "	1007	" "
5, animal, and ½ lb. of sugar	1027	15 grs. to each oz.
6, " ¼ " "	1016	4 grs. "
7, animal only	1020	no trace.
8, " "	1018	" "
9, animal, and pint of porter	1016	" "
10, " "	1018	" "
11, " 1½ pt. porter	1020	" "
12, " "	1022	" "
13, " "	1015	" "
16, " with 4 ozs. bread	1022	trace of sugar.

Unfortunately, the record of the quantity of urine passed daily has been mislaid; on this account I was anxious to repeat the experiments with sugar on another diabetic patient, and for this purpose Dr. Page transferred to me a patient who was under his care in St. George's Hospital.

A. T. was admitted into St. George's Hospital, Jan. 20, 1858, aged 43, married. She had been for two years under treatment at a dispensary. She was much emaciated, with pale, sallow face, and sunken eyes. The catamenia had been absent for fifteen months. She complained of excessive thirst and unappeasable appetite. She stated that her weight varied between 75 and 80 lbs., and that the urine had varied from 5 to 8 quarts in twenty-four hours. With a restricted, but not absolute animal diet, and three grains of opium, the urine varied between 4½ and 7½ pints. Sp. gr. 1030 to 1045.

On the 23rd of March she came under my care; the diet then was between 5 and 8 ounces of bread, 2 mutton chops, 2 eggs, 2 pints of milk daily, and 2 grains of opium, with some chalk mixture for diarrhoea, which began the previous day. She weighed 5st. 6lbs.; the quantity of urine was 5 pints; sp. gr. 1034. She drank only 3 pints of fluid, she said, and the quantity of sugar passed in the urine was 31 grs. to the ounce, or 3100 grs. in the 5 pints.

The 24th. the same diet and pill. There was no diarrhoea. She weighed 5st. 6lbs.; she passed 5 pints urine; sp. gr. 1042; she drank 3 pints. The sugar was 35 grs. to the ounce, or 3500 grs. in 5 pints.

The following day, feeling pretty well, same diet and medicine; weight, 5st. 6lbs.; urine, 5 pints, 1042; 3 pints of fluid were taken in twenty-four hours; the amount of sugar was 36 grs. to the ounce, or 3600 grs. in twenty-four hours.

The 26th, everything the same, except that 8ozs. of lump sugar were taken. She weighed 5st. 6lbs. The urine was 5½ pints; sp. gr. 1042; she drank 4 pints; the sugar was 39 grains to the ounce, or 4290 grs. in twenty-four hours.

27th, the same as yesterday, but diarrhoea commencing, chalk mixture was given. She weighed 5st. 4lbs.; the quantity of urine was 6 pints; sp. gr. 1042; she drank 3½ pints of fluid, and had eaten her usual quantity of bread, about 7ozs.; the amount of sugar was 40 grs. to each ounce, or in twenty-four hours 4800 grs.

28th.—Urgent diarrhoea; bowels acted seven or eight times. Violent hysterical fit. Ether mixture and opium injection were given. Her weight was 5st. 4lbs. The quantity of urine 5 pints; sp. gr. 1042, containing 38 grs. of sugar to each ounce, or 3800 grs. in the twenty-four hours. She drank only 3 pints. The sugar was omitted.

29th.—The diarrhoea was stopped. The weight was 5st. 5½lbs.; urine 5½ pints, 1042 sp. gr., containing 38 grs. to the ounce; or 4130 grs. in twenty-four hours.

30th.—No diarrhoea; no sugar; weight, 5st. 6lbs.; urine,

5 pints; sp. gr. 1042; contained 36 grs. to the ounce, or in twenty-four hours 3600 grs.

31st.—Still no sugar; weight, 5st. 6½lbs.; urine, 5 pints; sp. gr. 1043; contained 36 grs. to the ounce, or 3600 grs. in twenty-four hours.

April 1.—Bowels confined; 8 ounces of sugar were taken; the weight was 5st. 5½lbs.; the quantity of urine was 7 pints; sp. gr. 1040; containing 37 grs. per ounce, or 5180 grs. in the twenty-four hours.

2nd.—Feels very low and weak; no sugar was taken; the weight was 5st. 5lbs.; urine, 5 pints; sp. gr. 1041; amount of sugar, 36 grs. to the ounce, or 3600 grs. in twenty-four hours.

3rd.—Five pints; 1040; sugar, 35 grs.; or 3500 grs. in twenty-four hours. She complained of the sugar, and the experiments were discontinued. The following table brings the effect of the sugar clearly to view:—

	Weight.	Quantity of water.	Sp. Gr.	Sugar in 24 hours.	Fluids taken.	Bread.	Sugar
	st. lbs.	pints.		grains.	pints.	oz.	
1st day	5 6	5	1034	3100	3	..	none
2nd "	5 5	5	1042	3500	3	..	"
3rd "	5 6	5	1042	3600	3	..	"
4th "	5 6	5½	1042	4290	4	..	8oz.
5th "	5 4	6	1042	4800	3½	7	8 "
6th " violent diarrhoea	5 4	5	1042	3800	3	7½	8 "
7th "	5 5½	5½	1042	4130	3	5	8 "
8th "	5 6	5	1042	3600	3	7	8 "
9th "	5 6½	5	1043	3600	3	7	8 "
10th "	5 5½	7	1040	5180	3	7	8 "
11th "	5 5	5	1041	3600	3	8½	none
12th "	5 5	5	1040	3500	3	7	"

So that the amount of sugar in the urine, and the quantity of urine were increased on the days when sugar was eaten, excepting only on that day when violent diarrhoea existed.

In order to determine in which stage of diabetes this patient was, she was persuaded to give up all vegetable food of every kind, and all bread. Three eggs were taken in addition to the diet of meat and eggs which she was eating.

At the end of the

1st day of absolute animal diet she weighed 5st. 5lbs. The urine was 4 pints, sp. gr. 1042; it contained 31 grs. of sugar to each ounce. She drank 3 pints.

2nd day of absolute animal diet she weighed 5st. 4lbs. The urine was 4 pints, sp. gr. 1041; it contained 28 grs. of sugar to each ounce.

3rd day, animal diet; weight 5st. 4lbs. The urine was 4 pints, sp. gr. 1040; the sugar was 27 grains to the ounce.

The following day 19 ounces of bread were eaten, and the three eggs were omitted; the weight was 5st. 4½lbs. Four pints and a-half of urine were passed, sp. gr. 1040; the sugar was 34 grs. to each ounce.

The following day with the same bread; urine, 4 pints, sp. gr. 1041; sugar, 35 grs.

The following table will show the effect of an absolute animal diet, and of bread and meat:—

	Weight.	Quantity of water.	Sp. Gr.	Sugar in 24 hours.	Fluid taken.	Bread.
	st. lbs.	pints.		grains.	pints.	
1st day	5 5	4	1042	2480	3	none
2nd "	5 4	4	1041	2240	3	"
3rd "	5 4	4	1040	2160	3	"
4th "	5 4½	4½	1040	3060	3	10oz.
5th "	5 4½	4	1041	2800	3	10oz.

Each day was reckoned from one p.m. when the patient was seen; so that bread was taken on the morning of the first day, and by the results obtained on the fourth and fifth days when bread was eaten, it is probable that the amount of sugar found in the urine of the first day was increased in consequence of the early meal not being meat alone. The wrong conclusions that might be drawn from the specific gravity of the urine alone is well shown in these tables thus:—

	Sp. Gr.	Sugar in 24 hours.
When animal diet alone was taken	1040	2160 grs.
With animal diet, and bread, 10oz.	1040	3060 "
With animal diet, bread, 7oz., sugar, 8oz.	1040	5180 "

I have already said that it would be sufficient answer to Dr. Budd's cases, that I have seen other patients on the same treatment as regards diet get worse instead of better; the

analyses of the urine in the two cases I have here given, the one in the second stage, and the other in the third stage of diabetes, will show what a diet containing sugar and bread does effect in increasing the amount of sugar in the urine; and from all I have seen of the disease, it is better practice to follow the indication of lessening the amount of sugar in the urine, than to endeavour to cure the disease, as I have known a Homœopath try to do, by a specific of sugar and starch.

## ON IRIDECTOMY IN IRITIS, IRIDO-CHOROIDITIS, AND GLAUCOMA.

AS ATTACKED BY MESSRS. WHARTON JONES AND MACKENZIE.

By Dr. A. VON GRAEFE,

Professor of Ophthalmic Medicine and Surgery in the University of Berlin.

In No. 405 of the *Medical Times and Gazette* an article is published on my treatise on Iridectomy in Iritis, Irido-choroiditis and Glaucoma, which bears the names of two eminent colleagues, Messrs. Wharton Jones and William Mackenzie. I confess that all theorising on subjects which experience alone can decide, is repugnant to me; and I was therefore doubtful whether the article merited an answer or not, for the esteemed authors confess that they are without any personal experience on the questionable point, and confuse themselves in opposing my hundredfold facts solely with presumptions and conjectures. If, in spite of this, I have come to the conclusion to make a brief reply, both gentlemen need only look on it as a tribute which I pay to their earlier merits.

In the first place, these gentlemen set their faces against the importance which I ascribe to the presence of synechia posterior with regard to relapse in iritis. They concede the fact that persons who have been attacked by iritis and retained synechia posterior are more liable to a relapse of the disease than those where this did not occur; they nevertheless think it is necessary to give another explanation. Let us hear it. They say, "Synechia posterior, therefore, instead of being a cause of relapse, is an effect of the same causes, as that on which the tendency to relapse depends, viz. the ill-cured inflammation." If there appears to be any advantage to science and practice in this formula, I congratulate them with all my heart. Did such a *banale* truth give the right to these gentlemen to call my opinion, which solely expresses facts, collected with no small trouble, "a perverted view of the matter?" If they had only examined more minutely the neglected forms of iritis, which crowd to each oculist, and convinced themselves that the disposition to relapse generally vanishes as often as the laceration and sufficient extension of the synechia succeeds, they would then have had a more substantial basis for their opinion.

With regard to "the moderate employment of Belladonna," I do not know, if the gentlemen mean thereby the smearing of the remedy on the eyelids and forehead and the internal use of it. In this case, I should prefer to substitute the expression "uncertain treatment" for that of "moderate treatment." Yes; I maintain that such a restricted manner of application in iritis is altogether unphysiological, because experiments have long since proved that the mydriatic effect, as well as the decrease of the pressure, is only produced by the entrance of the remedy into the aqueous humour. When I place the methodic instillations of sulphate of atropine before all other means in the treatment of iritis, hereby is only meant that they are indispensable in the certain cure of this disease without synechia posterior, whilst antiphlogistics, mercury and paracentesis, appear necessary in many cases, but not in all. I employ all these methods, and I believe that I have decided indications for them, which the gentlemen could have learned better from some of their countrymen, who have followed for a considerable period my clinical lectures (I need only mention Dr. Mackenzie's own assistant, Dr. Brown), than from an Italian oculist, who passed a few days in this city to collect material for travelling reports, and who naturally took with him a bad impression of my clinique and person, because I am not accustomed to favour that kind of traveller, on account of the superficial nature of their studies and judgments.

When the gentlemen speak of "unskilful application," without taking thoroughly into consideration my manner of treatment, I am much obliged to them for their kindness to me as a *confrère*, and refrain from giving an appropriate answer, because it would not be adapted for a scientific journal.

With regard to the cessation of the ciliar-neurose, I have indeed said, that it often coincides with the dilatation of the pupil; but I have not by any means based it upon the mydriatic action alone. I have rather accumulated different reasons to bring it into *rappor*t with the action (of the atropine) which decreases the pressure, apart from the anodyne properties of the remedy.

On the employment of iridectomy in chronic iritis, with exclusion of the pupil, the gentlemen remark:—"The success of the practice does not appear to be very great." Immediately after this assertion, they quote cases of mine which have been cured by iridectomy, after having been despaired of without it. Upon what, then, is the above opinion (which forms essentially the motto of the whole article) based? The gentlemen themselves have operated just as little for these conditions as for the others that I have brought forward; they draw their opinion from my cases, and are pleased to come to an exactly opposite conclusion to that which ought naturally to follow. Is that to be called "logical reasoning?"

In speaking of iridectomy in certain grave affections of the cornea, the gentlemen accuse me of "great inaccuracy." Let us read again the passage (page 344, column 1, 4<sup>o</sup>), and judge of the superficial nature of their opinion. They remind me that, forsooth, the mere paracentesis in acute internal inflammation of the eye is useful, and renders remedies often successful which have been employed before this operation without result. What has that (which I do not certainly require to learn from these gentlemen) to do with spreading disease of the cornea? Do I classify with great trouble the indications for the iridectomy, and treat of them with regard to the special groups of diseases, merely for the purpose of seeing them all confounded together by Messrs. Wharton Jones and Mackenzie? I confess that I am accustomed to write my works for more attentive readers. Will the gentlemen hear again my opinion on this point; it runs verbatim with that which I have published before:—"In spreading affections of the cornea, particularly in infiltration with ulceration, I have only seen a decided benefit from paracentesis when the wound was allowed to remain open for some time, or when it opens periodically, so that more than a single momentary evacuation of the aqueous humour takes place, whilst in iritis and iridocyclitis a single discharge often paves the way for treatment." According to this I had sufficient grounds for pointing out here the effect of the iridectomy as something peculiar, opposite to paracentesis. If the gentlemen have other experience in this matter, i.e. in AFFECTIONS OF THE CORNEA, and not in INTERNAL OPHTHALMIA, I respect the same; but so much appears clear to me, that the "inaccuracy" did not lie on my side.

The gentlemen criticise yet further a case, in which I performed excision of one eye on account of sympathetic amaurosis of the other, and afterwards performed iridectomy on the second eye. I take the liberty, with all possible respect, to doubt their competency to judge in the matter, until they shall have given proofs that they have studied, first, the course of amaurosis with excavation of the optic nerve; and, secondly, the decrease of the pressure produced by iridectomy. I, for my part, can communicate to them, to my satisfaction, that the ophthalmoscope has now finally also given proof that the excavated papilla optici becomes, according to circumstances, level after iridectomy; and I hope that these proofs (which coincide with my ophthalmometric measurements of the curvings of the cornea in glaucoma), will be received in time, even by Messrs. Wharton Jones and Mackenzie.

Let us now pass to the point which is most important to me, viz. iridectomy in glaucoma. First, a modest question, relative to the "Medical treatment" which the above gentlemen have alluded to. Can they conscientiously declare that they have ever seen in glaucoma success resulting from a "well-directed Medical treatment?" or is this merely an empty figure of speech, which, from being often used with an ignorant public has now also escaped from oversight, where people who understand the matter do not lend it so credulous an ear? Or should the difference of opinion declare itself in

another manner? Should the gentlemen, still accepting obsolete views, trifle with the word, "Glaucoma," and now that more exact signs exist, depend only on the single symptom of a greenish dilated pupil? Oh! no; the celebrated names of both authors, who I have always been convinced followed the progress of science, guarantee that it is not so.

Let us leave the "Medical treatment of glaucoma," which, ill or well directed, leads the patients sooner or later to blindness, and let us proceed to the more important point of "Paracentesis." (a) That I have studied the action of paracentesis in glaucoma, my earlier publications in the *Archiv. für Ophthalmologie* (vol. i. sect. 2) prove. During many years (as mentioned in my works) I have employed paracentesis in all cases of acute glaucoma, and the number was truly no small one out of a Dispensary practice of over 6000 patients yearly, which I here direct. The final results of these attempts did not turn out happily, as the obtained improvement did not last in by far the greater number of cases, and ended finally in blindness. The methodical repetition of paracentesis was also without success, as the curative effect of it became always shorter and more imperfect. It was only after these results that I thought of a method of diminishing not only temporary, but permanently, the intraocular pressure, and that method I have certainly found in the excision of a portion of the iris. The same patients, who had become completely blind of one eye, in spite of "a well-directed Medical treatment, aided by paracentesis," were cured by the iridectomy on the second eye, after the glaucomatous process had attacked it, and have been under my observation during the last eighteen months, enjoying the most perfect vision, and without the slightest appearance of the disease. According to this there exists only between paracentesis and iridectomy the trifling difference, that in the former case the patients become blind, while in the latter they recover vision and remain so. This is proved by incontrovertible facts, which Messrs. Wharton Jones and Mackenzie, if they will only pay attention to, cannot gainsay. Would I have ventured to proclaim a new method of curing a disease up to this time incurable, without such decided results, acquired by several years' observations? Was it under these circumstances "unnecessary to superadd a new proceeding to a long known one?" If I were to go more into detail, it would be only repeating what I have said in my earlier publications on the subject; as the English translations of the latter will, however, soon appear, I can refer the public to them with confidence, and until this time refrain from further discussion on the subject, in the certain hope that the impartial reader will judge me more justly than Messrs. Wharton Jones and Mackenzie have done.

In conclusion, a word more on the *résumé* of those gentlemen, which runs as follows:—"Dr. Graefe's practice of iridectomy appears to us so opposed to the plainest principles of surgery and common sense," etc. This assertion does not only express a great contempt for my faculty of observation, but at the same time insults the great number of oculists who have adopted the procedure. It cannot have remained unknown to the gentlemen, that my introduction of iridectomy has been received on all sides in Germany with joy, and that its effect has already been corroborated by many Professors, who occupy chairs of ophthalmology. I willingly pardon older, and so highly deserving men, for their want of that elasticity requisite for the immediate reception of new views; I also know how to honour an obstinate opinion, when it arises from strong conviction; but I should indeed have expected more moderation from the Nestor of English ophthalmology. I see, with regret, that Dr. Mackenzie maintains a procedure to be bereft of "common sense," which Ark, Hasner, Gull, Busch, Langenbeck, Sperino, and others, name one of the most thankworthy improvements in ophthalmological science, and this without having procured the slightest experience of his own on the subject. The future, which I look forward to with confidence, will decide who shall have to regret his too hasty expressions in this matter, and who, overcome by the power of facts, shall have to bow his "own sense" before "common sense."

(a) I speak only of the paracentesis of the anterior chamber, as the paracentesis of the vitreous humour in glaucoma, according to my experience, gives not more relief, and has many disadvantages.

## ENCYSTED ENCEPHALOID TUMOUR OF THE ORBIT,

PRODUCING PROTRUSION OF THE EYE-BALL AND LOSS OF VISION.—  
OPERATION.—RESTORATION OF THE SITUATION, AND GRADUALLY  
OF THE FUNCTIONS OF THE EYEBALL.

By J. ZACHARIAH LAURENCE, F.R.C.S. M.B.

Surgeon to the South London Ophthalmic Hospital.

Elizabeth P., aged 28, was admitted into the South London Ophthalmic Hospital on Jan. 4, 1858. She had noticed the right eyeball protruding from its socket for upwards of a twelvemonth; the eyeball had, in addition, an inclination downwards, and its mobility was somewhat impaired. The eyeball itself did not appear enlarged; and when its interior was examined ophthalmoscopically by Mr. Wharton Jones and myself, nothing but a congested state of the retinal and choroidal vessels was apparent. Underneath the stretched upper eyelid a smooth lobulated tumour was felt, about the size of a bean. She had no tumour on any other part of the body. For the last six weeks her sight had been gradually failing her. When she came to me she could not distinguish persons' faces with that eye, and printed paper appeared as if blank. She had never experienced any double vision or ocular spectra.

By a transverse incision in the upper eyelid I came down upon the small tumour felt before the operation, but soon found that it formed but an insignificant part of a large growth that filled the outer part of the socket of the eye, and reached to the very bottom of that cavity. I removed it partly with the knife, partly with the left index-finger. The blood welled up very profusely from the gap in the orbit; but this was arrested almost immediately by cold water. No lint was placed in the wound; nothing but a piece of lint was laid over it.

The tumour weighed upwards of half an ounce, was lobulated on its surface, and inclosed in a firm cyst of cellular tissue. Its naked eye characters, on section, were those of encephaloid cancer, without the slightest pigmentary discoloration; its microscopic features were peculiarly distinctive—those of cancer.

In a couple of days the wound in the eyelid had united, and the eyeball regained its normal situation. No suppurative action ever took place in the orbit. The patient can now distinguish persons and printed paper with the eye, the functions of which are being more and more restored every day.

This case presents several features of interest.

1. The strict limitation of the tumour to the orbital cellular tissue, without involving the eye-ball, optic nerve or ocular muscles; that this was so, follows from the anatomy of the growth itself, and from the gradual restoration of the functions of the eye, after its removal.

2. Although the cavity left in the orbit after the operation was, from the size and deep extension of the tumour, necessarily very considerable, yet no inflammatory or suppurative action ever set in in that cavity. This result I ascribe to the fact, that the wound in the eyelid closed nearly immediately after the operation, and that thus the artificial cavity made in the orbit was entirely excluded from the air. The operation might, in this point of view, be compared with the equally favourable results aimed at, and so generally attained, in the so-called "subcutaneous" operations, exceeding, however, these in practical interest, from the much greater severity of the operation performed. I presume that the subsequent pathological processes resemble those that ensue in the absorption of an apoplectic clot in the brain.

3. The next most remarkable point is the occurrence of a pure encephaloid (non-melanotic) tumour in the orbit at such an age as 28. This is certainly very unusual. Of twenty-four cases Mr. Wardrop knew of fungus hæmatodes in the eye or orbit, twenty were under twelve years of age. Desault's experience was the same: "Plus du tiers des malades qu'y (à l'Hôtel Dieu) a opérés Desault étaient audessous de douze ans." The late Mr. Travers reports a case where a child was born with the eye-ball the size of a walnut, from medullary cancer. (a) The present case offers then an

exception to the very general rule, that cancer of the eye and orbit in infancy and childhood is medullary, in middle age melanotic.

P.S.—The patient can now distinguish the letters of large type.

## THE LONDON

## PRACTICE OF MEDICINE AND SURGERY.

## THE ROYAL LONDON OPHTHALMIC HOSPITAL.

### REPORT OF OPERATIONS PERFORMED FROM MARCH 1st TO APRIL 16th, 1858.

By Dr. C. BADER, Registrar to the Hospital.

#### EYELIDS AND LACHRYMAL APPARATUS.

Two cases of nævus, in each of them the tumour was of the size of a pea; one was situated in the skin of the lower lid, and the other in that over the lachrymal sac; the former was excised (with the aid of the compressorium forceps), and the latter was touched with a small cautery.

Removal of a cyst from near the right upper eyebrow in two cases; they contained sebaceous matter, and small pale hairs; the wound of one of them, which was of the size of a large walnut, suppurated considerably, but had completely healed within five weeks.

Of four cases of inversion of the eyelashes, with thickening of the palpebral edge, three were treated by removal of the portion of skin including the eyelashes, one by grooving the outer surface of the fibro cartilage. In one case (in which the compressorium forceps were used) the operation was followed by considerable swelling of the lid and erysipelas, but the patient recovered without deformity.

A case of eversion of the lower lid (caused by repeated inflammation of the conjunctiva) was treated by excising an oval piece of the conjunctiva and fibro cartilage, near to and parallel with the palpebral edge; the wound had healed within four weeks, but as the eye was insufficiently protected, a small V-shaped piece, of the thickness of the lid, near the outer canthus, was removed, and in a week this having healed, the patient was treated in the usual manner for eversion and stricture of the lower lachrymal canal.

One case of diseased lachrymal sac, of three years' duration, in a strumous patient, the skin much infiltrated, treated by Desmarre's plan (the case is still under treatment).

In a case in which both sacs had been cauterized, mentioned in the report of Sept. 1857, the discharge has reappeared in two months on the one side, and on the other four months after the operation: both eyes had remained watery during this period.

As far as can be ascertained, that portion of the sac which extends from the lower orbital edge backwards and inwards, has been obliterated by the cautery; but the portion immediately behind the orbicularis tendon, and next to the nasal orifice of the sac, had remained unobliterated; this portion, on either side, has been treated lately by passing No. 6 probe, and by three weeks' treatment lachrymation has ceased, and the discharge become considerably less. This is an accidental combination of Mr. Bowman's and Desmarre's treatment. One case of removal (with scissors) of a pea-sized, hard, painless tumour, which had been firmly attached to the sclerotic and inner corneal edge. This patient, aged 34, had a similar tumour removed from the same spot three years ago. Microscopically, the first-mentioned tumour showed large cancer cells in different stages.

#### STRABISMUS.

Ten cases of internal strabismus, of ages varying from 4 to 19, were operated on subconjunctivally; in eight, both external recti were divided; in two, only the one of the most squinting eye; in the latter cases, slight strabismus continued.

In two cases, in which external strabismus existed during the effects of chloroform, there was parallelism after its

(a) Synopsis of Diseases of the Eye, by Benjamin Travers, F.R.C.S. Second Edition, p. 210.

influence had disappeared, and slight internal strabismus returned after three weeks, which was effectually remedied by a second operation.

#### IRIS.

One case of detachment of iris adhesions in the pupillary area, followed by an increased accommodation of the operated eye; no active inflammatory symptoms at the time of operation. One case of formation of an artificial pupil, the outer half of the cornea being opaque; the portion of the iris withdrawn was left in the corneal wound, near its inner lower edge. Five cases of chronic glaucoma, in all of which the ophthalmoscope showed a cup-shaped entrance of the optic nerve, were treated by an excision of a quarter of the iris,—in two cases in both, in three in one eye only. In the eyes operated on, the cup was recognised before the operation; one of the eyes suppurated, two of them were not improved; one was slightly and one considerably improved by the operation as far as outward appearances go. The thinning and discolorations of the sclerotic appear to be proportionate to the advance of the disease.

#### CRYSTALLINE LENS.

Five cases of double and four of single extraction of senile cataract; in five of the former, and in two of the latter, the patients were able to read when leaving the Hospital, in from three to six weeks after the operations; of the two other cases, one globe suppurated,—this patient suffered from an affection of the spine, and a sudden movement during sleep thirty-six hours after the operation caused the escape of the vitreous; the other patient, suffering from emphysema and hypertrophy of the heart, left by his own wish ten days after the operation; he had then fair perception of light, the corneal section had united, the conjunctiva was edematous, and there was grey lens substance in the anterior chamber. In one of the double extractions, slight prolapse of the iris occurred with one eye; the pupil, which was drawn upwards, appeared adherent to the capsule and the anterior chamber, which was lessened by the fluid accumulated between the iris and the lens capsule. The pupillary adhesions were opened with one needle, and within two days the iris became flat, the anterior chamber larger, and the pupil more central. In a case of traumatic cataract of fifteen years' standing, and without perception of light, the pupil was distended by a chalky white mass which protruded into the anterior chamber, and as this was apparently the cause of pain and irritation, it was extracted with the cannula forceps by a lower corneal section. No vitreous escaped. (The ophthalmoscope had showed detachment of the retina behind the black pupil.) When the patient left the Hospital thirteen days after the operation, the pain had ceased. In three cases of unilateral equally grey cataract, spontaneous commencement at the ages of 35, 37, and 41, treatment was commenced by breaking up the anterior surface of the lens, and keeping the eyes under the influence of atropine. In three cases of cataract in children of the ages of 16 months, 3 and 9 years, in which the cataractous change occupied the lens to the extent of the pupillary area, its surface was broken up with one needle. In cases in which there is only a small white dot on the lens (probably on the inner surface of capsule), and the remainder transparent, no operation has been employed. In one of the congenital cases the cataract (?) presented itself in both pupillary areas as an irregular white flat substance. In the right eye, the transparent substance in the pupil was broken up with one needle, and a grey fluid filling the anterior chamber was removed three days later with the broad needle and scoop. In three weeks the patient could tell the time by a small watch. In the left eye, the white substance having been removed with cannular forceps and scoop, the eye became during the next day painful, though atropine had been applied.

Four cases of false membrane behind the pupil after extraction were treated with the needle.

Three cases of linear extraction; in two the grey lens substance had been removed several times before, and in one (a boy), the lens had been broken up three months previously, and the grey flocculi in the anterior chamber was removed with the broad needle and scoop. In one of the former cases the operation was followed by purulent infiltration of the corneal wound, and by hypopyon, which subsided on medical treatment without injury to vision.

#### EXCISIONS OF THE GLCBE—eight operations.

Of these, one was for injury, two for staphyloma of the

ciliary region, two for staphyloma corneæ, two for "chronic glaucoma," and one for epithelial cancer encroaching upon the sclerotic.

Mr. Dixon has modified the usual operation by first dividing the internal rectus, so as to leave a long stump of tendon to seize by, then dividing the optic nerve, after which the globe is turned out of the orbit, and the remainder of the soft parts are separated.

Mr. Bowman contracts the opening in the conjunctiva by a suture, when the bleeding has entirely ceased.

Among the pathological changes of the above globes the following may be mentioned:—

In globes with staphyloma corneæ, and several fistulous openings of long standing in the staphylomatous portions, the vitreous humour had a peculiar consistence. It was of normal amount and transparency; but, when cut or lifted, offered more than usual resistance to the instruments. To venture a theory, its more fluid constituents had drained away, leaving its thickened, though transparent, framework.

## HOSPITAL NOTES.

### CANCEROUS GROWTHS OF BOTH SIDES OF THE FACE IN A YOUNG CHILD.

A case in which two distinct growths of cancer had taken place almost simultaneously in a young child, was brought under our notice by Mr. Critchett, at the Moorfields Ophthalmic the other day. The disease affected the cellular tissue about the orbits and temples, and on one side had probably originated within the superior maxilla itself. Both eyes were closed by the oedema of their lids, but in neither instance was the globe itself involved. The appearances presented externally were almost symmetrical, the temples, cheeks, eyelids, &c. being prominent, and crossed by large blue veins. In the mouth, however, the left side only was affected. The left upper gum and palate were much swollen, all the teeth had come out, and in their place was a fungous bleeding ulcer. The disease had, according to his mother's account, spread very rapidly, having originated only three months ago. It had been noticed on the right side about a month after its first symptoms on the left. There was no structural connexion between the two growths. The patient was a remarkably well-grown boy, of 4 years old. In almost all cases, we believe, in which cancer occurs in early life, a history of hereditary tendency may be traced. In this instance, two of the boy's mothers' uncles (on the maternal side) were reported to have died of cancer of the face, beginning in the lip. It was not known that any blows on the parts affected had ever been received. A remarkable rapid departure of health had been observed during the growth of the tumours.

Cases of cancer in both breasts are not so very uncommon, one such was recently under observation at the London Hospital, and one in which both breasts have been extirpated, is at present under Mr. Hutchinson's care in the Metropolitan Free. We believe, however, that instances of symmetrical growths of cancer on the two sides of the body are very much more rare in early life. One or two are on record in which, in young children, both eyes were affected. All who saw the case we have above noticed, however, acknowledged that they had never seen its parallel.

### EVACUATION OF A LARGE HYDATID CYST IN THE BACK.

A woman, of middle age, had been attending Mr. Chance's Out-patient room, at the Metropolitan Free, for some weeks, on account of a large prominent swelling in the left loin. It was suspected to be a lumbar abscess, but against this idea were the facts that there was little or no weakness in the back, and that the woman appeared in good health. Fluctuation had for some time been apparent, and had become quite superficial, and, a puncture having been refused, at length spontaneous ulceration took place. On the next day of her attendance, Mr. Chance noticed a white membrane sticking in the opening which had formed, and, on removing it, found it to be an acephalo cyst hydatid. By pressure about a hundred cysts, varying in size from a bantam's egg to a pea, were got away, the tumour then appearing to be nearly empty. During

the next few days, however, many more escaped. They were translucent, and evidently living. The ulcer still remains open. No constitutional disturbance whatever has attended the opening of the cyst. It appears probable that it is connected with the intra-muscular cellular tissue only, and not with any internal organ.

## THE PROVINCIAL PRACTICE OF MEDICINE AND SURGERY.

### STATISTICAL REPORT OF THE PRINCIPAL OPERATIONS PERFORMED DURING THE YEAR 1857.

(Continued from p. 429.)

The subjoined Report comprises the following Hospitals:—Addenbrooke's (Cambridge), the Bristol General, the Cheltenham General, the Cumberland (Carlisle), the Derby General, the Dorset County (Dorchester), the Dundee Royal Infirmary, the Glasgow Royal, the Gloucester, the Hull, the Leeds, the Leicester General, the Liverpool Royal, the Liverpool Southern and Toxteth, the Queen's, Birmingham, the Sheffield General, the South Staffordshire (Wolverhampton), the Staffordshire General (Stafford), the Sussex County (Brighton), the West Norfolk and Lynn (Lynn), the York County.

#### HERNIOTOMY.

**Case 1.**—Addenbrooke's: Mr. Humphry.—A man, aged 60. Hernia inguinal, strangulated forty hours. The neck of the sac was the stricture, and the sac was consequently opened. Recovered, without ill symptoms. **Case 2.**—The Cheltenham: Dr. Eves.—A woman, aged 53. Hernia femoral, and strangulated forty-eight hours. Sac opened. A large portion of adherent omentum was left in the sac, and afterwards sloughed off. Recovered. **Case 3.**—The Berkshire.—A woman, aged 39. Hernia femoral, and strangulated four days. The sac was opened, and a knuckle of very dark intestine exposed. Well-marked peritonitis followed, but was subdued by calomel and opium, &c. Recovered. **Case 4.**—The Dorset: Mr. Curme.—A feeble woman, aged 51. Hernia femoral, and strangulated fifty-six hours. Sac opened. Recovered. **Case 5.**—The Leeds: Mr. Smith.—A stout man, aged 61. Hernia inguinal, and of large size. Strangulation had existed only twelve hours. Sac not opened. Recovered. **Case 6.**—The Leeds: Mr. Teale.—A feeble woman, aged 67. Hernia femoral, of small size, and strangulated forty-eight hours. Sac opened. Recovered. **Case 7.**—The Leeds: Mr. Smith.—A man, aged 42. Hernia inguinal, strangulated thirty-one hours. Sac not opened. Recovery. **Case 8.**—The Queen's, Birmingham: Mr. West.—A man, aged 32. Hernia inguinal, and strangulated three days. The sac was opened, and was found to contain omentum only. Recovery. **Case 9.**—The Bradford: Mr. Poppleton.—A lad, aged 16. Hernia femoral, and strangulated five days. Sac opened. Recovered. **Case 10.**—The Bradford: Mr. Poppleton.—A woman, aged 52. Hernia femoral the size of a hen's egg, and strangulated six hours. Sac not opened. Recovered. **Case 11.**—The Bradford: Mr. Terry.—An infant, aged eight months. Hernia inguinal, strangulated twelve hours. Sac not opened. Recovered. **Case 12.**—The Cheltenham: Dr. Eves.—A man, aged 66. Hernia inguinal. Symptoms of strangulation had existed eight hours. Sac not opened. Recovered. **Case 13.**—The Cheltenham: Dr. Eves.—A man, aged 62. Hernia inguinal, and strangulated three days. Sac opened. Recovered. **Case 14.**—The Bristol General: Mr. Coe.—A man, aged 29. Hernia congenital. Sac opened. Recovered. **Case 15.**—The Bradford: Mr. Terry.—A lad, aged 19. Hernia inguinal, the size of a goose egg, and strangulated three hours. Sac not opened. Recovered. **Case 16.**—The Gloucester: Mr. Wilton.—A woman, aged 69. Hernia femoral of large size, and strangulated twenty-eight hours. The sac was opened, and a large mass of adherent omentum was cut away. The intestine was reduced. Recovered. **Case 17.**—Addenbrooke's: Mr. Humphry.—A labourer, aged 66. Hernia inguinal, and strangulated twenty-four hours. Sac opened. Recovered without a bad symptom. **Case 18.**—The Cheltenham: Mr. Eves.—A woman, aged 49. Hernia femoral, and strangulated two days. Sac opened. The symptoms were completely relieved at first, but returned the next day, and continued till she died. Death took place on the seventh day. The autopsy showed a fold of bowel obstructed by adhesion to Poupart's ligament. **Case 19.**—The Bradford.—A woman, aged 66. Hernia inguinal of small size, and strangulated twenty-four hours. The sac was opened and was found to contain faecal matter, the gut having given way. Death from collapse next day. **Case 20.** The Bradford: Mr. Parkinson.—A man, aged 38. Hernia inguinal, and strangulated several days. The sac was opened, and the intestines found gangrenous. Death on the third day. **Case 21.**—The Leeds: Mr. Hey.—A man, aged 60. Hernia large, inguinal. The gut had been incarcerated for a week, but urgent symptoms had only been present for twelve hours. The sac was opened, but the hernia consisting of cæcum was only partially covered by it. The symptoms continued, and death followed on the third day. The autopsy showed the bowel perfectly free, but acute peritonitis had been set up. **Case 22.**—The Liverpool Royal: Mr. Long.—A stout man, aged 22. Hernia scrotal of large size, and strangulated eleven hours. Symptoms severe. The sac was opened, and both intestines and omentum returned. Death from peritonitis on the second day. **Case 23.**—The Derby: Mr. Gisborne.—A woman, aged 40. Hernia femoral, strangulated four days. She had steadily refused to have the operation performed during the last three days of the period. Sac opened and intestine reduced. Death from peritonitis on the third day. **Case 24.**—The Berkshire: Mr. Moxhay.—A healthy man, aged 40. Hernia inguinal of large size, and strangulated fifteen hours. Sac opened. Death on the fifth day from entero-peritonitis.

#### TREPHINING, &c., OF THE SKULL.

**Case 1.**—The Bradford: Mr. Terry.—A lad, aged 19, admitted with a compound fracture of the skull, and laceration of the membranes, with injury of the brain. The depressed bone was elevated. Death three hours afterwards. **Case 2.**—The Bradford: Mr. Parkinson.—A boy, aged 3. The skull had been fractured, and the dura mater torn. Elevation and removal of some portions of the shattered bone. Death, with hernia cerebri, on the twelfth day. **Case 3.**—The Bradford: Mr. Parkinson.—A lad, aged 15, admitted with a compound fracture in the left parietal region, with injury to dura mater, and loss of cerebral substance. Two portions of bone which had been driven in, and were quite loose, were removed. The lad recovered, and the parts healed over. **Case 4.**—The Derby: Mr. Johnson.—A labourer, aged 60, was admitted with a compound fracture of the posterior part of the skull, caused by a brick falling on his head. He was in coma. The trephine was used, and the depressed portion elevated; but he remained insensible, and died an hour afterwards. At the autopsy the whole surface of brain was found covered with clot, and the anterior lobes were much contused. **Case 5.**—The Liverpool Northern: Mr. Hamilton.—A girl, aged 19, admitted with compound fracture of the left parietal bone. The trephine was used, and a triangular depressed portion was elevated. Death on the fourteenth day. She had been sensible throughout. **Case 6.**—The Sheffield: Mr. Gregory.—A man, aged 30, admitted on Feb. 28, having a lacerated scalp-wound two inches in length, corresponding with the middle part of the coronal suture. There was no evidence of fracture, nor any symptoms of cerebral mischief, excepting slight deafness. Up to the eighteenth of March he gradually improved. Two or three epileptic seizures then occurred, and were followed by paralysis of the right side. A small puffy swelling was now discovered over the anterior edge of the left parietal bone. An incision having been made at this spot, a piece of bone, two inches long by one broad, was found quite loose, and was removed. The dura mater was not lacerated. Two days later the paralysis had passed off, and no more fits had occurred. The man remained very ill for some weeks, but ultimately made a perfect recovery. **Case 7.**—The Glasgow.—A man, aged 26, admitted with a severe compound fracture of the vertex of the skull. Elevation of bone. Doing well at date of report. **Case 8.**—The York: Mr. Husband.—A carpenter, aged 50, admitted with a severe compound fracture of the frontal bone. Several portions of detached bone were removed. The dura mater was extensively exposed, but not torn. Recovered without a bad symptom.

SATURDAY, MAY 1.

## POISONING IN OUR BARRACKS.— THE ANTIDOTE.

In our number for April 3, p. 352, we noticed how our soldiers were being slowly, steadily, and surely poisoned in our barracks, by the pernicious influence of the impure air they are constantly compelled to breathe. They live in these barracks in numbers generally of about eighteen men together in one apartment, which affords from 400 to 500 cubic feet of space to each man. According to Sir B. Airy, in his evidence before the Army Sanitary Commission (Qy. 3039), the regulation which orders this very limited supply, apportioned, it seems, by the engineer department, is not strictly observed either in hospital or in barracks; and moreover, the appropriation of space on the floor by beds is determined according to the cubic feet of air which the room can contain. (Qy. 3044.) In rooms of considerable height, the men must therefore be very much crowded, and when we remember that they live by day in these rooms, that they eat and drink in them, and that they sleep by night in them, can we wonder that under such inconsistent management and arrangement general discomfort is great, sickness is frequent, and mortality is high? Let us now shortly direct attention to the means which science tells us may ameliorate to some extent this state of things; and more especially to the specific antidote for the poisoning, namely—VENTILATION.

It is not only necessary that men may have sufficient air to breathe, but it is necessary to provide air for the apartment itself in which they live, as well as for the men who inhabit it. The influence of impure air is not only exercised upon the men through their breathing organs, but the surface of their bodies, their clothes, their seats, their tables, beds and bed-clothes, the walls of the apartments, in short, the free surfaces of everything in contact with the air of the place, becomes more and more impure, a harbour of *fomites*, a means of impregnating every cubic foot of air with poison, unless the whole apartment has its atmospheric contents continuously changed, so that everything animate and inanimate is freshened by a constant supply of pure air. If ventilation is efficiently carried on, the whole air which a chamber or room is able to contain, must be kept in a state of continuous change. It is not sufficient that the quantity of air merely necessary to fill and fill again the lungs of a man be brought within reach of his pulmonary organs. Air continuously supplied, in quantities of about four cubic feet per minute, is sufficient for this. A soldier, if he is to enjoy health, must be permitted to luxuriate in fresh air. He must have his room constantly filled with it, as pure as can be obtained from round his barrack. To preserve a room in a healthy state, it is not merely necessary that sufficient air be present to enable a man to fill his lungs every time he

breathes; there ought to be a constant circulation of pure air, so that quantities not less than 2200 cubic feet per bed per hour shall simultaneously go out and enter the apartment—that its rate of movement shall be so imperceptible that no draught or current can be felt—and such that the temperature of the room shall not be suffered to fall below 60° Fahr. It is this constant supply of pure air, and a sufficient provision for the outlet of poisonous gases, contaminated atmosphere, and noxious emanations, which merit the first consideration of those who would improve the sanitary condition of our soldier. It is “the want of fresh air,” not “the want of cubic space,” which kills our soldiers in their barracks-rooms. We do not mean for a moment to insinuate that cubic space ought not to be considered in the construction and occupation of an apartment. On the contrary, we are fully convinced that a definite amount of cubic space, and especially the preservation of definite proportions in the height and width of a room, are most important elements, not only as regards convenience merely, but as regards the requisite diffusion of the fresh air, the ease of ventilation, and economy in heating. To give the air of a ward or barrack-room the highest possible degree of *freshness*, the amount of air admitted to circulate through it should be in quantities of not less than 4000 cubic feet per bed per hour. In this luxurious condition as to fresh air, the adjustment of cubic feet in the best proportions as to width and height is of great importance; and it must not only be sufficient, but the number of beds must be such, that an allowance of from 2200 to 4000 cubic feet of fresh air to every bed per hour may move continuously through the apartment, in a definite direction, with a motion so gentle and imperceptible, that no current or draught can be appreciated; and could such a state of things be maintained with a constant temperature, not below 60° Fahr., we should have reached the height of perfection in the art of ventilation.

There are two methods by which the art of ventilation may be accomplished; namely—1. An *artificial* method by machinery. 2. A *natural* method by doors, windows, and fireplaces aided by various forms of ventilating shafts. The former is used in several Hospitals, and in a large number of public and private establishments, generally in combination with arrangements for warming the air. Such combinations are introduced not only for economy in heating, but also to ensure the passage through the apartment of a much larger quantity of air in cold weather, than could be introduced unless the air were at the same time warmed.

Numerous objections have been taken with justice to systems of *artificial* or *mechanical* ventilation. In the first place, the necessity for such methods of ventilation implies such defects in the architectural construction of the place to be ventilated, that natural methods of ventilation are unable to keep it in a healthy state. A most important objection to artificial ventilation also is its cost. It is, moreover, not only cost in the first instance, but the current annual cost required to conduct the operations of the ventilating apparatus, as well as to provide for the “wear and tear” of machinery. If we refer again to the Report of the Royal Commissioners relative to the sanitary condition of the army, the value of which cannot be over-estimated by students of sanitary science, we find some very interesting statements of Dr. Sutherland on this point. (Appendix xli. p. 457.) In his description of the artificial systems of warming and ventilation in the Parisian Hospitals, it is shown that the first cost of the apparatus for warming and ventilating under the plan selected by the French Government is somewhat under £11 per bed, the annual outlay about £2 6s. per bed, and the capitalised cost £34 per bed. To ventilate a room containing eighteen beds by such a method would therefore cost about £612! Numerous artificial methods have been tried in this country, of which that in use in the new building of Guy's Hospital

may be regarded as a most expensive method, while the method of pumping air into an apartment, as described by Dr. Neill Arnott, may be regarded as the most simple of artificial methods, and the least expensive. Other most important objections belong to systems of artificial ventilation. Among these may be especially noticed,—1. The very large amount of space generally occupied by the apparatus and machinery. 2. The difficulty of introducing the apparatus and arrangements into buildings other than those where arrangements have been made from the first by the builder for their special introduction. 3. The impracticability in general of applying artificial systems of ventilation to old buildings. 4. Irregularity in the supply of air to different parts of an apartment; and, lastly, the use of machinery implies the occasional occurrence of accidents to it, which necessarily stops the whole process of ventilation.

On the whole, therefore, it is now a very prevalent belief that of the many systems of ventilation which have from time to time been proposed, the most complicated and expensive is that which has generally been found to be the least effective; and, on the contrary, where ventilation is the most perfect, there the system is found to be simple and natural.

"Ventilation," says Dr. Sutherland, "is an art in the exercise of which we cannot supply intelligence by machinery;" and we find that Miss Nightingale gives expression to an opinion somewhat similar when she says, "if attendants cannot be trained to keep rooms ventilated without draughts, there is a defect of intelligence, and attendance on the sick is not their calling."—(Q. 10,039.)

We take this opportunity of expressing the high opinion we entertain of the evidence of Miss Nightingale before this Commission. Her whole evidence is distinguished for the profound knowledge it exhibits in matters of the most minute detail, and is remarkable alike for the depth of thought and intellect which has been brought to bear on every subject which affects the welfare of our soldier; it is distinguished, moreover, by the boldness and moral courage of its tone, and by the clearness and lucid arrangement of its matter.

Doors, windows, and fireplaces, have hitherto been the most natural means of ventilation, sometimes also aided by shafts or openings direct to the open air from the interior of apartments. To effect ventilation in this natural way, one or more fireplaces are necessary in a room, and the throat of the chimney ought to be as high as our heads. "Our grandfathers' lofty fireplaces," says Miss Nightingale, "are the greatest loss in modern house architecture. The little low fireplaces of this date bring the best current of air below the stratum in which we are breathing. With our present natural system, to breathe the best air we must not be more than six years old, or we must lie down."

By natural means of ventilation fresh air is intended to enter by a variety of contrivances, such as by opening windows, making apertures in the floor or the ceiling, or in the wall above the windows; and to prevent draughts various appliances of wire-gauze have been ingeniously contrived to disperse the air, or break the force of its current. In general, however, no certain provision is made to carry off the contaminated air, which is allowed to find its way out as best it may; or the same opening admits air, and at other times gives vent to it.

In the introduction of pure air to a building by any method, regard must be paid—

1. To the quantity of air introduced.
2. To the mode in which it is introduced; so that
3. The movement of a large volume of air may go on easily, continuously, and imperceptibly; that while all sensible draught is avoided on the one hand, any loss of force may, on the other hand, be prevented by sufficiently large conduits and apertures.

4. That the natural action shall be as much as possible constant and self-regulating.

5. That the method adopted shall be such as to ensure the immediate removal of the emanations from the apartment, generated by the process of life in the healthy as well as in the sick.

6. That the circulation of fresh air shall be so complete, that draughts shall not cause effluvia to be driven, or suffered to accumulate in any one part of an apartment.

Of few of these contrivances can it be affirmed that the results are very satisfactory; the proportion between the demand and supply of air being in general most uncertain, a small waste is too often supplied by an unbearable current, or the close and stifling sensation arising from imperfect respiration, denotes an insufficient supply of an important necessary of life. The old proverb says,—

"If cold wind reach you through a hole,  
Go, make your will, and mind your soul."

And one of our highest authorities on ventilation (Dr. Arnott) writes: "The safe ventilation is that which enters copiously, but almost imperceptibly, like the gently moving air under a tree or an open arch, in a nearly calm summer day."

Let us apply these principles to elucidate the means of improving the state of barracks; and we are glad to be able to state that a commission is now actively at work (in terms of the original recommendation made in the Report of the Royal Commissioners, p. lxxvi.) systematically respecting every barrack, devising and executing works of necessity (and doubtless of mercy also), with such expedition as the available resources of Government permit. When we state that this acting Commission consists of Captain Galton, a distinguished officer of Engineers; Dr. Sutherland, well known as pre-eminently versed in the practical application of sanitary science; with Dr. Burrell, of the Army Medical Department; and having as chief of the Commission, Mr. Sidney Herbert; we are certain that ere long every barrack in its turn will be brought to a healthy and satisfactory condition.

The poisonous emanations necessarily discharged from the bodies of living beings, issue warm from the body, and are specifically lighter than air; and finding no opening for escape higher than the throat of the chimney, in places where apertures above that do not exist, they tend to rise and to fill all the upper part of a room. Currents of air passing beneath doorways to fireplaces, or from window to window, or from door to window, carry very little of the poison with them; and it is in this impure atmosphere that men usually breathe, namely, in the upper strata of air, with their heads above the level of the purer currents.

In this country we cannot maintain ventilation by windows, doors, and fireplaces, under all circumstances; and the numerous contrivances to replace these natural means of ventilation fail generally for one or more of the following reasons, namely, they are either inconstant in their action, or they will not act without causing draughts, or while they act in admitting air no provision is made for foul air being carried off; and, perhaps the most usual defect in the aids to natural ventilating arrangements arises from the inlets for air being too small.

It is when doors and windows are closed that ventilation is most of all required. We cannot, in general, in this country, sleep in a room at night with windows and doors open. Doors in general are intended to be kept shut, and so are windows, except on particular occasions.

Many beautiful contrivances have been devised for assisting natural ventilation, and although perhaps few of them realize in every instance so much as sanguine admirers expect of them, yet they all are attended with most beneficial results by simply directing attention to important principles put to practical tests in effecting one of the most important neces-

Sities in sanitary administration, namely, regulating the supply, and providing for the demand of fresh air.

Of the many improved devices for ensuring natural ventilation, we have lately seen one patented by Mr. M'Kinnell, of the Athenæum Club, Glasgow, which more completely fulfils the requirements of perfect ventilation than any with which we are acquainted. It seems to us that in this country it cannot fail to fulfil all the ordinary conditions in which natural ventilation requires to go on. A working model is to be seen at the Society of Arts, to which we direct the attention of our readers, and some account of the plan will be found in another column.

### THE WEEK.

Diphtheria or diphtherite, that is the question! Dr. Farr, for the Registrar-General, says diphtheria, and we think he is right. Bretonneau gave the name to the disease from its most obvious characteristic—the exudation of false membrane on the mucous membrane of the fauces—after the Greek, *διφθέρα*, membrane. But the suffix, *itis*, used to denote inflammation, is clearly objectionable. It leads to the false notion that the disease is of a sthenic or inflammatory type, and is etymologically incorrect, as it implies that the pellicle or membrane—the diphthera—is inflamed; an obvious absurdity. For the future, therefore, the example of Dr. Farr should be followed, and we may use *DIPHTHERIA* until a better word is coined. Our readers may be interested by referring to Fothergill's account of the putrid sore throat, or *Angina Membranacea* of his time, and comparing it with the disease which is, after so long a period of intermission, again becoming epidemic in this country.

Mr. Griffin has requested us to state that he hopes to meet such of the Poor-law Medical Officers as wish to attend as part of the deputation to the Poor-law Board, at the Board, Whitehall, next Friday, May 7, at 12 o'clock, noon, or at a preliminary meeting, 11 o'clock on the same day, at the Ship Hotel, Charing-cross. The day and hour have been fixed by the Board to receive the deputation, and we would urge the following sentences from Mr. Griffin's letter upon the attention of our readers:—"It is very desirable to have the countenance of some of the Members of the House of Commons; I therefore beg all the Medical men who have influence with their representatives will ask them to attend, that by their presence, at least, they may testify their willingness to see the position of the Poor-law Medical Officers improved. I have reason to believe the Poor-law Board are not insensible to the hardships we endure, and that the deputation will pave the way for changes of great importance. I trust those gentlemen who have not already sent in their petitions to the House of Commons and Poor-law Board will do so without further delay."

Considerable interest was excited at the last meeting of the Royal Society by a paper of Dr. Scott Alison on his *Stethophone*, or differential stethoscope. The advantages to be derived from the use of this instrument are the appreciation of slight differences in the character and duration of the pulmonary and heart sounds, normal and abnormal, and the power of distinguishing between synchronous and rapidly succeeding sounds in different parts of the chest. Some curious acoustic phenomena have also been made out—the deprivation of hearing in one ear when the opposite ear receives the same sound in a degree rather more intense—and the division of a composite sound into two parts, one part being heard in one ear and the other part in the opposite ear. Lastly, while

the same sound is heard in the ear in which the sound is received with more intensity, the sound conveyed with lesser intensity to the other ear is not lost. It fails to cause any sensation in the ear to which it is conveyed, but distinctly augments the sound in the more favoured ear. This is a beautiful illustration of the wise provision which has ordained that both ears may serve their purpose, contributing without confusion as to the source of sound to a common result.

Mr. Sands Cox has just received £500 on account, as a part of the testimonial to be presented to him, in acknowledgment of the years of hard labour he has devoted to the Queen's College and Hospital at Birmingham. He has vested the sum in trustees for the purpose of founding two scholarships of £10 each, to be held for two years, to be competed for as a test of the proficiency of students of the College and Hospital in Clinical Medicine and Surgery. This is an act which does honour to our Profession.

The conviction of the Master of Newington Workhouse for illegal disposal of bodies for dissection has been quashed on a point of law. The facts are these:—Notice to attend the funeral of the deceased had been sent to the relatives. They accordingly attended, were shown the body in a coffin, and saw it screwed down. They were then requested to wait in another room, and they afterwards followed a coffin to the grave, believing it to contain the body of their relative, whereas the real body was detained, and afterwards sent to Guy's Hospital for dissection or examination, but to be ultimately buried. The question was whether this came within the Anatomy Act, which provided that the master of a workhouse was justified in sending the body of a pauper dying in the workhouse to any hospital for examination, unless he was prohibited by the nearest relatives of the deceased, who should require the body to be interred without examination. We really do not pretend to understand the judgment of the Chief Baron and Mr. Justice Wightman, but it seems to lead to the conclusion that the fraud which led to the relatives withholding their refusal to allow dissection, instead of increasing the punishment, has led to a reversal of the verdict of the jury. If this be law it is opposed to justice and common sense, and the sooner the law is amended the better.

The annual microscopical *soirée*, given by the master and wardens of the Apothecaries' Society, took place on Tuesday evening last, when a great number of scientific gentlemen, both in and out of the Profession, assembled together to inspect the various objects of interest presented to their notice. As on former occasions, the microscopical illustrations were not the sole feature of the evening, but the walls of the ancient hall were covered with diagrams representing objects of natural history, and with a splendid series of photographs; while the tables exhibited a profuse display of stereoscopes, anatomical and physiological specimens, and living plants, including flowering acacias, rhododendrons, ferns, palms, and grasses. Some magnificent living cycadaceous plants, lent by Mr. Yates, were placed in contrast with a series of fossil remains of the same order, contributed by Dr. Bowerbank. In one of the rooms was exhibited Ruhmkoff's Induction Electrical apparatus, which, by means of a coil of wire four miles long, and a Grove's Battery, exhibited the most striking effects of electricity in its passage through a vacuum, and through different kinds of gases, the electrical current in each case giving rise to a beautiful

display of various colours. The microscopical objects illustrated various departments of natural history, pathology, and crystalization, many of the specimens exhibiting the living actions of plants and animals; and the diagrams on the walls were in many instances magnified representations of the same minute structures. On Wednesday morning, ladies were admitted to the display, which was further enhanced by a copious display of flowers from the Society's gardens, and from private contributors. Among the microscopic exhibitors, besides the various makers of the instruments, the more conspicuous were Dr. Carpenter, Dr. Bowerbank, Dr. Ansell, Dr. Beale, Mr. Ward, and Mr. Woodward. We have frequently expressed our gratification at witnessing these social and scientific *réunions* of the members of our Profession, and we have seldom been more gratified than by the last meeting at Apothecaries Hall.

We deeply regret to announce the sudden death of Dr. Robert Harrison, Professor of Anatomy in the University of Dublin. Dr. Harrison was apparently in his usual health on Thursday, the 22nd ult.; operated at Steevens' Hospital that morning; lectured at the University; and, so late as seven in the evening, met a professional brother in consultation. During the night he was seized with an attack of apoplexy, which proved fatal at eleven o'clock in the forenoon of the 23rd of April. Dr. Harrison was a fellow of the Colleges of Surgeons of London and Dublin, and a M.D. of Trinity College, Dublin, Assistant Surgeon to Steevens' Hospital, Visiting Medical Attendant of the Central Criminal Lunatic Asylum at Dundrum, etc. Having been since 1827 joint Professor (with Dr. Jacob) of Anatomy and Physiology to the Royal College of Surgeons in Ireland, he was in 1844 elected to the Chair of Anatomy and Surgery in Trinity College. In a Prelection, introductory to the Medical Session of 1855-56, delivered before the University of Dublin, and published in our thirty-second volume, Dr. Stokes, the Regius Professor of Physic, observes, "that up to the year 1848 Anatomy and Surgery were taught by the one professor. The advance of knowledge in both branches had been such that it became desirable to separate the chairs of Anatomy and Surgery; and I am proud to say that Professor Harrison was an earnest advocate of the new arrangement, although it entailed a pecuniary loss to himself." Dr. Harrison was a most able lecturer, remarkable for the ease and fluency of his delivery. He was author of the well-known "Dublin Dissector," which has reached a fifth edition, and of the "Surgical Anatomy of the Arteries," which, having passed through four editions, is nearly out of print. Professor Harrison took an active interest in the proceedings of the several bodies with which he was connected, and his loss will be deeply felt in scientific circles in Dublin.

We have heard, through one of the leading Professional men in Edinburgh, that since the following resolution was passed by the College of Surgeons in that city, no Fellow of either College of Physicians or Surgeons has been known to meet a Homœopath in consultation. The resolution was passed in 1851, under the presidency of Mr. Syme. Our Colleges might do well in following such an example. It was resolved unanimously:—

"That the College having considered a series of resolutions transmitted by the Royal College of Physicians in regard to Homœopathy, feel called upon to express their opinion that the system so designated being entirely inconsistent with the principles professed by candidates for the diploma of the College of Surgeons, any Fellow or Licentiate who practises it, or countenances others in doing so, by meeting them in consultation, will justly incur the disapprobation of the College."

A full account of the deputation of the Medical Corporations to Lord Derby will be found below. We have little to say on the subject that we have not said before, except that while Mr. Cowper seems very sanguine as to the success of his bill, the opposition of the Corporations will probably be too strong to be overcome. As Mr. Duncombe obtained leave on Wednesday evening to bring in a Bill "to define the rights of the members of the Medical Profession and to protect the public from the abuses of Medical Corporations," Parliament will have four Bills to deal with. The conversation on the "Sale of Poisons Bill," at the conclusion of the Meeting, is worthy of attention. The Bill of the late Government is abandoned—in our opinion most unfortunately—while the present Government have accepted a Bill prepared by the Pharmaceutical Society. The College of Physicians and the Apothecaries' Society it seems are to give a joint report on this Bill, and we trust they will point out to Lord Derby the impropriety of leaving the sole power of examining and licensing those who sell poisons to a Society who might do something to restrict the Sale of Poisons, but would not be likely to make regulations interfering with their own business. The organ of the Society argues that as suicide and murder by knives and pistols cannot be put down by Act of Parliament, *ergo* it is of no use restricting the Sale of Poisons,—we should only drive people to the cutlers and gun-makers! The Pharmaceutical Chemists form about 2500 out of 16,000 dealers in drugs. They are evidently delighted at the overthrow of the Bill of the late Government, and if they are allowed to frame a Bill, the probability is that the interests of the Chemists will be considered rather than the safety of the public.

#### MEDICAL REFORM.—DEPUTATION TO LORD DERBY.

On Tuesday afternoon a deputation from the various Medical corporations of the metropolis waited on the Earl of Derby, at his official residence, Downing-street, in relation to the bills now before Parliament on Medical Reform. The deputation was accompanied by Sir R. Levinge, M.P., Mr. P. Benet, M.P., Mr. Headlam, M.P., and Dr. O'Connor.

The PREMIER having apologised for the absence of Mr. Walpole, who, but for engagements at the committee on the bill for the Reform of the Corporation, would have been with him,

Dr. MAYO introduced the deputation, and stated that it consisted of himself, the president; Dr. Alderson, the treasurer; Dr. Hawkins, the registrar of the College of Physicians; and Dr. Jeaffreson, senior censor of the College of Physicians; Mr. Stanley, the president, Mr. Lawrance, and Mr. Caesar Hawkins, from the Royal College of Surgeons; Mr. Simoons, Mr. Tegar, and Dr. Ansell, of the Society of Apothecaries. These gentlemen, he said, had met to assure his lordship of the unanimity of the various medical corporations in favour of a bill, the provisions of which would be laid before his lordship. That bill was the last that had been brought forward. The subject which they were about to bring under the notice of the noble lord had been going on for fifteen or sixteen years, and had kept the public in a state of anxious suspense. The subjects, which were of extreme importance, embraced such topics as registration, reciprocity of practice throughout the three kingdoms; a very essential condition, in order that a gentleman might not go into another part of the kingdom, and find the practice wholly different to that in which he had been brought up. The bill of Mr. Headlam, which secured these points, came before the House of Commons last year; and on the second reading obtained a majority of 147. Why it was then dropped was a question into which he would not enter; but he contended that, unless something were done to do away with the uncertainty which now existed, it had been much better that the matter had never been mooted. The gentlemen who were now agitating this question had nothing to gain by it, either their fortune

or their ages precluded that; and it was, therefore, reasonable to suppose, that they had nothing at heart but the interests of the country. He would not further occupy his Lordship's time, but call on Dr. Hawkins, Registrar of the College of Physicians, who had taken a part in the proceedings regarding every bill on the subject of Medical Reform which had been brought forward during the last twenty-four years, to read the communications they had received from the Medical Corporations of Ireland and Scotland.

Dr. HAWKINS, at the call of the last speaker, read letters from various corporations, all of which united in the views of the gentlemen who formed the deputation. They were from Edinburgh, Glasgow, and Dublin. He also read a letter from Dr. Acland, of Oxford, regretting his inability to be present with the deputation, and stated that the council of the University expressed their willingness, should a measure of this description be passed, to relinquish its power of granting licences, on condition that it should only continue to educate, and examine generally, in sciences more immediately preliminary to medicine. There was, he declared, great unanimity in favour of Mr. Headlam's bill, and equal unanimity against the measures of Mr. Cowper and Lord Elcho, which would either fail to cure the evils, or introduce fresh evils by destroying the influence of the Medical corporations of England, Scotland, and Ireland. It was nearly twenty-four years ago since he was examined before the select committee of the House of Commons, obtained by Mr. Warburton, on the subject of Medical education. Since then the Profession had been kept in a state of excitement; those who were qualified to practise in one part of the kingdom were not in another. There were twenty licensing bodies, which undersold one another, and a practitioner who had been passed by the one was not regarded as passed by the other. Even the lawyers themselves did not know who was qualified and who was not.

The Earl of DERBY: Are you speaking of qualifications as Physicians, or as Surgeons and general practitioners?

Dr. HAWKINS: It is doubtful whether one or the other.

The Earl of DERBY wished to know if their object was to found certain qualifications for each branch of the Profession, and separate registration for each.

Dr. HAWKINS said they wished to have a classified registration, such as is proposed in Mr. Headlam's bill. They considered that by such a course the Government would restore to a great Profession its usefulness and its credit, at the same time removing the evils which had so long continued to lower its character in public estimation, and otherwise operate to the prejudice of the whole body of the Profession.

Mr. HEADLAM said he had good ground of complaint against the late ministry, who would neither bring in a bill themselves nor allow any one else to pass one. The late period of the session when the division on the second reading of his bill took place last year, which was carried by a majority of 147, rendered it impossible for him to carry it through, and even if the bill passed the Commons, there was no hope of its getting through the House of Lords. He was, therefore, compelled to abandon the idea of carrying it any further, and hence the failure of any legislation in the last session of Parliament. Although there are great differences of education and qualification among Medical practitioners, still, from the interviews he had with the representatives, not only of the corporations, but of those opposed to the views of those bodies, he found there was an urgent desire to bring the question to a final settlement; and, notwithstanding the opposition of the late Government to his bill of last year, he was successful in obtaining for it the support of a great majority of the House of Commons. He would have introduced the bill this session, but he always thought it was the duty of the Government to take up the question; and he had a communication with the Government on the subject, when on a sudden the bills of Lord Elcho and Mr. Cowper were introduced. Neither of those bills expressed the opinions of the members of the Medical Profession at large, and therefore ought not to become law. The principle of his bill is to recognise all existing corporations, giving to them that influence in promoting the welfare of the public and the Profession to which they are entitled; to establish uniformity of qualification and education throughout the United Kingdom, to establish a registration of all duly-qualified Medical men. He urged on his Lordship the advisability of either taking up the

question as a Government measure, or giving to it such support as would secure its passing. From his knowledge of the feeling of the House of Commons on the subject, he could assure his Lordship that if taken up as a Government measure, that his bill would have the same, if not a greater, amount of support than when last before the House: it would speedily become law.

The Earl of DERBY: That is a very sanguine expectation, considering that it has been before Parliament for the last four-and-twenty years. He was sorry to take up the time of the deputation, but as his attention was not directed to the bills, and as Mr. Walpole was absent, he was desirous of knowing the leading points in which the bill of Mr. Headlam differed from those of Lord Elcho and Mr. Cowper.

Mr. HEADLAM gave in detail the various points in which the three bills differed.

The Earl of DERBY: Mr. Walpole takes a great interest in this question, and I regret he is not able to be here to-day. However, he has sent me a letter in which he very briefly puts forth the principles on which all Medical legislation should be based. They are as follow:—Equality of education and qualification throughout the United Kingdom; registration of all duly qualified practitioners, and a recognition of all existing institutions. He (Lord Derby) believed that to be a very proper view of the question.

Mr. LAWRENCE said that Mr. Headlam, to his mind, had made himself completely master of the subject of Medical legislation, and he thought it a pity that the subject should be taken out of his hands. The bills of Lord Elcho and Mr. Cowper were not such as the corporations required. They were opposed to the interests of the corporations, and, therefore, could not be for the good of the Profession at large. Lord Elcho's bill is a complete farce on legislation. It institutes an inferior grade in the Profession; the examination is "a little go," and it ignores altogether the existing corporations. Under his bill all are to be Licentiates of Medicine and Surgery, while Mr. Cowper's bill does not once recognise the title of Physician, Surgeon, or Apothecary.

The Earl of DERBY: Is there not a great difference between England and Scotland, as far as relates to qualifications?

Mr. LAWRENCE: Persons qualified to practise in Scotland, were not so in England; and, although English practitioners were never desirous of passing the Tweed, Scotch practitioners looked to London as the great field of their ambition. The Scotch qualifications are inferior to those of England. The corporations were conversant with the wants of the Profession, and they were the best judges of what the Profession required; and anything more degrading than the passing of the Bills of Lord Elcho and Mr. Cowper could not be contemplated. On behalf of the Royal College of Surgeons of England, he stood forward to state that its examinations were conducted in the best manner; and as a proof of the superiority of its diplomas, the number examined annually exceeded that of all the other Colleges of Surgeons in the United Kingdom. It has a museum not enjoyed by any other country; its existence is based on a Royal Charter; and although not required by the provisions of that charter to sustain that museum, there were given annually large sums for its support. Lord Elcho and Mr. Cowper by their Bills were seeking to place their unhallowed hands on the Medical Corporations of the country to promote their annihilation. He therefore implored Lord Derby to stand between the Medical Corporations of England, whose fame was for ages untarnished, and those who sought by mischievous legislation their destruction.

After some further conversation,

The Earl of DERBY said, that from what he had heard, the bill of Lord Elcho was very far from the thing, although they must not forget that he had only heard ex-parte statements. He should be much obliged if they would leave in his hands the letters from the corporations and copies of the bills, and he would promise to give the subject his most careful consideration. His Lordship, in conclusion, said he would take the opportunity of asking, seeing so many eminent men present, whether they knew anything of the "Sale of Poisons Bill," and whether it met their approval.

Dr. HAWKINS: We have not considered it part of our duty, and on the part of the gentlemen who accompany me, I beg to inform your Lordship that we know nothing about it.

The Earl of DERBY: It will be in your recollection, that in the last session of Parliament a bill was introduced on the

subject; since my accession to office the attention of the Government has been called to it in the House of Lords, and I felt it my duty to communicate with the Pharmaceutical Society. The Council of that body have drawn up a bill, a copy of which they have placed in my hands; and I shall feel obliged if you will take the two, consider their different clauses, and give me your opinion on them.

After some conversation, during which Dr. O'Connor suggested that the subject was one of as much importance to Apothecaries, coming strictly within their province,

Dr. Hawkins said that, with Lord Derby's permission, the College of Physicians, with the aid of the Apothecaries' Society, would report to his Lordship on the different clauses of the old Bill, and that drawn up by the Council of the Pharmaceutical Society.

The Earl of Derby: The subject is one of great interest, and one on which I am anxious to obtain all the information I can.

The deputation then withdrew.

## PROGRESS OF MEDICAL SCIENCE.

### Selections from Foreign Journals.

#### CASE OF DEATH FROM CHLOROFORM.

By Dr. BINZ.

Dr. Binz of Bonn having to operate upon a cicatrix situated on the forehead of a strong and healthy student 23 years of age, had him laid on a sofa, the head and chest being propped up erect. For some years past he had been in the habit of drinking eight or ten glasses of beer daily, but had taken only two or three the day prior to the operation. After removing any article of clothing that could have caused compression, and found that the actions of the heart and pulse were normal, the latter beating about 90, chloroform was administered. This soon produced great excitement, the patient starting up, and tossing his arms about, complete collapse, however, rapidly supervening; all this happening within ten or twelve seconds. Water was dashed in his face, the soles of his feet were brushed, and a finger was passed into the mouth so as to ascertain that the tongue and epiglottis were in their normal positions. Artificial respiration was now instituted, and continued for a full hour, the friction of the soles being persisted in. Dropping melted sealing-wax on the chest and electricity were also resorted to,—all in vain, for the patient was dead. At the autopsy the upper surface of the brain was deficient in blood, but a great abundance of very dark-coloured blood flowed away when the incisions were made for the removal of the brain. The meningeal arteries in different places contained air-bubbles; but the other arteries, which were of a bluish-red colour, did not exhibit this appearance. The pia mater was easily separable; and the bloody points, on making sections of the brain, were numerous, but no extravasation could anywhere be found. The medulla oblongata was also in a normal condition. The heart was, as Casper states it always is in these cases, relaxed, pale, and empty of blood, while both ventricles contained abundant coagula. The valves and substance of the organ were completely normal. At the highest calculation only six drachms of chloroform could have been administered; and an exact chemical examination has proved its purity.—*Deutsche Klinik*, No. 13.

#### EXCERPTA MINORA.

*Penetration of Lumbrici into the Liver during life.*—Professor Mattei furnishes an additional example of the rare case of lumbrici found in the liver. In the body of a man, aged 40, numerous lumbrici were found in the alimentary canal; and on incising two projecting portions of the convex surface of the liver, in each of these a lumbricus was found. The two cavities in which were the worms were but little larger than themselves, and contained a turbid fluid, holding pus globules in suspension, and numerous ova of the worms; the cavities were lined with layers of concreted fibrine; and the surrounding parenchyma was injected and indurated, as if from chronic phlegmasia, evidently proving that the worms had gained access to the organ long prior to death. In the case of one

of the cysts its continuity with the biliary passages was demonstrated by the passage of water. Dr. Senderini also related a case in which he had found a lumbricus, 13 centimetres in length, in the biliary duct.—*Annali Omodei*, vol. clxi. p. 609.

*Plantain in Diarrhœa of Children.*—M. Anciaux states that he has found a mucilage prepared from plantain seeds (*plantago major*) of great use in the catarrhal form of diarrhœa, and also in the mild inflammatory form.—*Presse Belge*, 1857. No. 7.

*Ossification of the Stylo-hyoidean ligament.*—M. Achard exhibited to the Pathological Society of Brussels a very curious specimen, viz: a complete ossification of the cartilaginous prolongation which unites the styloid apophysis to the os hyoides. In the adult, this is replaced by certain fibres known as the stylo-hyoidean ligament; but, in this specimen there is not the slightest trace of ligamentous fibres, the ossification being complete. The specimen was met with in a man, aged 45, in whom probably the primary cartilaginous condition had never been replaced by the ligamentous tissue.—*Ibid.* 1858, No. 13.

*Reunion of the separated Pavilion of the Ear.*—Dr. Linoli relates the case of an old woman, aged 70, who, falling down stairs, separated the entire pavilion of the ear, which only hung by a small thin strip of skin. The author, called to her immediately, resolved to try and obtain union by keeping the bleeding parts in contact. After encouraging the discharge of blood from the parts by tepid water, he exactly adapted the surfaces according to their natural relations, and kept them *in situ* by means of strapping and bandages. These were removed in part on the fourth day, the strapping not being taken off until the sixth, when adhesion was found to have become completely established. The dressing was replaced, and in less than a month the cure was completed, excepting that the sensibility of the pavilion continued impaired.—*Omodei Annali*, vol. clxi. p. 42.

*Hydrocele treated by Electricity.*—Dr. Rodolfi, of Milan, has applied electricity for the cure of hydrocele in four cases, and reports very favourably concerning its effects, not only the fluid disappearing in all, but its reproduction being prevented in three of the cases. Bumsen's or better still Daniel's pile should be employed.—*Presse Belge*, 1857, No. 52.

*Red Colour of the Valves of the Heart in Alcohol Poisoning.*—Dr. Voltolini, after enumerating the not very certain signs of alcohol poisoning that are known, describes an appearance he has met with, in order that attention may in future be directed to the point. It consists in the cinnabar red colour of the pulmonary and aortic valves. The colour cannot be wiped off, and gives to the valves a very beautiful appearance. A remarkable quantity of dark thin blood was found also in the vena cava ascendens and the subclavian vein. Dr. Santius met with a similar appearance of the valves in 1856. It remains to be seen whether this appearance is characteristic of alcohol poison alone, or is found in other affections inducing fluidity of blood. The author found no mention of it on the perusal of a great number of accounts of autopsies, in which such fluidity prevailed.—*Berlin Med. Zeitung*, 1857, No. 12.

*New Local application in Erysipelas.*—M. Anciaux speaks in high terms of the following application for erysipelas and some other cutaneous affections. Alum reduced to impalpable powder, 30 parts; white precipitate, 1 part. Rub up well together, and place the powder in a bottle, and then add from 90 to 100 parts of glycerine. Shake the bottle until the mixture assumes a creamy consistence, and repeat the shaking whenever the application is about to be employed.—*Presse Belge*, 1857, No. 19.

*Sulphur and Nux Vomica in Hæmorrhoids.*—M. Van Holsbeek recommends the following formula as being rapidly beneficial. R. Sulphur. loti, sacchar. alb.; aa, ʒj.; ext. strych. nuc. vomic. gr. vj.; mucil. gum. tragacanth. sufficient to form twenty-four lozenges. The patient is to take two the first day, increasing the dose by one daily until six a-day are taken. He now rests a few days, and then diminishes the dose in the same proportion, until he gets to the two again. If the cure is not complete, he must begin again; but it is rare to find the treatment required for more than a week. During its continuance alcoholic drinks and a too stimulating diet are interdicted. The treatment is applicable to all stages of uncomplicated hæmorrhoids.—*Ibid.* No. 22.

*Columba in Vomiting.*—M. Lami observes that while we are thankful for any new therapeutical agent, we must not

forget the value of those we possess. Among these, fresh-powdered calumba has always in his hands proved a most efficacious remedy in nervous, spasmodic, or atonic vomiting, as in that of pregnant women. He gives 15 grains with a few spoonfuls of wine, an hour before meals, three times a-day.—*Ibid.* No. 26.

*New Hemostatic.*—After prolonged experience, M. Lami strongly recommends the following hæmostatic: *B.* Decoct. rhataniæ, 300 parts; alum, 60 parts. If the mixture is to be given internally, 70 parts of syrup are to be added. When given internally, 10 drachms may be taken three times daily; while for external use it may be employed as injection or lotion. Its action is prompt and efficacious in almost any variety of hæmorrhage.—*Ibid.* No. 32.

## GENERAL CORRESPONDENCE.

### ENCOURAGEMENT OF HOMŒOPATHY.

LETTER FROM SIR CHARLES LOCOCK, BART.

[To the Editor of the Medical Times and Gazette.]

SIR,—By the tenor of a letter in your number for April 24, it might be assumed that I was in the habit of meeting and consulting with Homœopaths. I beg to assure you, that, except on a few occasions taking a patient direct from a Homœopath back to the orthodox mode of practice, I have never done anything of the sort, and have never consulted with any one of them.

I am, &c.

C. LOCOCK.

Hertford-street, April 27.

### LETTER FROM DR. SIEVEKING.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have observed with the greatest satisfaction that you have not hesitated to attack the practice which, if report is to be believed, prevails extensively, of Medical men meeting Homœopaths in consultation. There can be no middle course between utter repudiation or adoption of the Hahnemannian doctrines. He who coquettes with them, ceases to belong to the legitimate school of medicine, and the Medical man, who for the sake of pandering to public ignorance, does not shrink from meeting the Homœopathist in consultation, proves that he has not the honour and dignity of the Profession at heart. Have we devoted years of toil and anxious labour to a fallacy, or are we to be in doubt as to whether we are following the call of true science, when we seek to afford relief to our suffering patients by the light of physiology, pathology, and therapeutics? No one is more ready to admit the imperfections that yet surround our knowledge, than I am; and I hesitate the less to do so because it is only by a recognition of our own faults that we can hope to mend them; but he only can know himself and correctly estimate his powers, who stands upon the firm basis of inductive science or of revealed religion. The latter has no bearing upon the question at issue; but if medicine has not a firm basis in the former, the sooner we all abandon it entirely the better. Knowing that we have that basis, knowing that in spite of many imperfections, we are daily approaching nearer to truth in our most beneficent Profession; and knowing, moreover, the readiness with which the general public seize upon any excuse to accuse medicine of inconsistency and vagueness; it behoves us all, high and low, to show that we have an assurance of the reality of our science, that we believe in what we have learnt and what we are daily practising. I feel conscious, Sir, that I will and do grant to others that freedom of thought and action which I claim for myself; but, as liberty may not be confounded with license, legitimate science cannot without degradation associate or identify itself with its bastard offspring. I say, then, Sir, without any hesitation, that the line beyond which our self-respect as honourable men and members of the noblest of all professions, should forbid us to go, is easily drawn. We do not wish to persecute or prosecute the Homœopathist. If he can conscientiously pursue his calling, so much the better for him; if he does so without the support of his conscience, it need be no concern of ours. But it does closely concern us whether we shall directly or indi-

rectly sanction what we know to be, if not a wilful deception, yet a deplorable fallacy. It nearly affects us whether we will, by meeting Homœopathists in consultation, avow to the public that Medicine and Homœopathy are convertible terms,—that it matters not whether we follow the one or the other.

I have no intention to enter upon a controversy. In what I have written I have simply wished to maintain a principle. Circumstances appear to me to demand that the Medical Profession should clearly enunciate their decision; and, as a member of that Profession, I venture to express the opinion which I hold, and the creed by which I am governed. I do not wish to be accused of pusillanimity, and therefore, perhaps more candidly than wisely, beg to subscribe myself,

Sir, your very obedient servant,

EDWARD H. SIEVEKING, M.D.

Fellow of the Royal College of Physicians,  
and Physician to St. Mary's Hospital.

17, Manchester-square, W.

April 24, 1858.

### LETTER FROM DR. RANKING.

[To the Editor of the Medical Times and Gazette.]

SIR,—I have observed with much satisfaction the resolutions of the Reading and neighbouring practitioners in reference to Homœopathy. They have set an example which should be universally followed. The events of the past few weeks, in which we have had the melancholy spectacle of a London surgeon of repute linking himself to this imposture, and the senior surgeon of a provincial hospital "acting under" one of its apostles, prove forcibly that the time has arrived when those members of our Profession who would preserve their character for honesty of principle must no longer forbear to speak out, and must, moreover, by their practice, show that they make no distinction, in the point of Professional and moral rectitude, between the avowed practisers of quackery and those who, by meeting such at the bedside, tacitly countenance them, and are equally deserving of the scorn of honourable minds.

I am, &c.

W. H. RANKING.

Norwich, April 18, 1858.

### LETTER FROM DR. SEMPLE.

[To the Editor of the Medical Times and Gazette.]

SIR,—The two writers who have addressed you, under the signatures of "Vox Populi" and "Justa aut Nihil," and who rather seek information on the subject of Homœopathy than write in defence of that so-called system, deserve rather more attention than the professed followers of the Homœopathic doctrines. As those two writers evidently desire to be instructed in the principles of the globulistic system, their wishes will without doubt be gratified by the perusal of your admirable leading article of last week; and if they really desire to see a more detailed and very masterly exposition of the principles and practice of Hahnemann, they cannot do better than peruse the work written by Dr. Simpson, entitled, "Homœopathy, its Tenets and Tendencies," in which the whole subject is most fairly, ably, learnedly, and temperately set forth. If, after the perusal of that work, they should still lean to Homœopathy, they are beyond the influence of legitimate reasoning, and may be safely left to indulge in their own fancies.

But, on the supposition that your two correspondents really know nothing at all about Homœopathy, and that their judgment has only been partly swayed by some cunning, or foolish, or dishonest people, I think that they deserve a reply to some of the hypothetical questions which they propose.

I should remark, however, in the first place, that "Vox Populi" seems to have been rather hardly used, by his own account, at the hands of some of our Profession. A Medical man in the present day, who makes depletion and calomel his principal agents, and "employs in turn almost every drug in the Pharmacopœia, using one as antidote to another," must be a *rara avis in terris*, and I sincerely sympathise with your correspondent in having had his constitution so victimized. It is only charitable to inform "Vox Populi," that the system of which he not unjustly complains is by no means in accord-

ance with the principles of modern Medical science; and I am almost inclined to believe that he must have fallen into the hands of some irregular practitioner, combining the ancient principles of Dr. Sangrado with the more modern ones of the illustrious Morison and the no less distinguished Holloway.

If the alternative, therefore, were to be bled, and starved, and purged, for all and every disease, on the one hand, or to be allowed to be left to the unaided efforts of nature on the other, I really believe that I myself should agree with "Vox Populi" in preferring the latter course; because the cases requiring bleeding and depletion are comparatively very few, while the trivial cases which may, and often do, get well without medicine are very numerous; and therefore, by leaving my ailments to get well of themselves, I should stand a better chance, on the whole, of getting well, than if I allowed myself to be bled and starved under all circumstances.

But, among the very first principles of rational medicine, we are taught that the diseases of mankind, like their constitutions, are of a very different, and often of an opposite character, and that they therefore require very various, and often opposite, methods of treatment; and I am sure that it will afford consolation to "Vox Populi" to be told that the prevailing tendency of the Medical Profession in the present day is to administer tonics and stimulants, in place of depressing agents, although I do not pretend that this course is indiscriminately adopted in every case.

Again, the members of the Medical Profession endeavour to acquire a knowledge of the human frame, of the diseases to which it is liable, and of the remedies likely to be serviceable in treatment, by a careful inquiry into the structure and functions of the human body, and into the nature of the various chemical and mechanical agents by which its powers are improved or impaired; and this kind of knowledge requires several years for its acquisition. But the system of Hahnemann discards all such knowledge as useless, and relies solely on the symptoms felt, or supposed to be felt, by the patients; and the medicinal agents are sought for among substances many of which are known to be inert, and all of which are used in doses so minute as to be utterly useless. Hahnemann himself was a mere visionary, and his "system" is a mere compound of folly and indecency, as any one will discover who will take the trouble to study it.

But "Vox Populi" is, I think, entirely mistaken in supposing that the members of the Medical Profession have any objection to his treating himself upon the Homeopathic system, if he choose to do so, or to his calling to his assistance a Homeopathic practitioner, if he prefer him. He has as much right to take the Homeopathic globules as he has to take Morison's pills, or to use Holloway's ointment, or any other quack preparation which he may please to patronise.

But now comes the important question. He has undoubtedly no right whatever to expect me, or any other respectable man, to meet the quack vendor of Morison's pills in consultation; neither can he in justice expect me to meet in consultation another quack, who pretends to cure all diseases by the administration of infinitesimal globules, which are known to possess no chemical properties whatever. My presence at any such consultation would imply that I gave a certain countenance to the quackery, and I should be justly involved in the moral guilt attending any evil consequences that might ensue.

With regard to Mr. Fergusson, I should be very sorry indeed to condemn him for setting a broken leg, whether the patient were a Homeopath or not; but such a charitable and necessary act is very different from a deliberate and systematic practice of meeting and consulting with Homeopathic quacks, with whose principles Mr. Fergusson, as an educated Surgeon, can have no feeling whatever in common.

It is quite true that the globulists assume the titles which belong to the Profession, and not a few of them, as is well known, assume these titles surreptitiously and dishonestly; but this is only the old story of vice arraying itself in the garb of virtue. The Profession entirely disowns them, as it disowns Dr. Morison, Dr. Holloway, Dr. Coffin, and many others, who are, nevertheless, at full and perfect liberty to gull the British public, if John Bull likes to submit to it.

I am, &c. ROBERT H. SEMPLE.

[To the Editor of the Medical Times and Gazette.]

SIR,—“A Junior Hospital Physician” has wasted a good deal of excellent passion on the man of straw which his own indignation has created; he has expended a deal of energetic treatment on a disease of his own making. Who but he ever proposed “to shake the hand of fellowship with the practitioners of this Homeopathic subtlety,” or to do otherwise than clearly declare his disapprobation of it? To do this is quite compatible with the course of conduct which I advocate, and I only wish that your correspondent and others of his class could see that it is their violent abuse and unreasonable opposition under the appearance of a high tone of honour (I give them credit for a mistaken sincerity), which gives its main importance to Homeopathy.

Does a “Junior Hospital Physician” think he will aid the judgment of any one by the use of such terms as these,—“tricks, villainies, cheats, swindlers, knavery, lies, arrogance, craft, impostors, boasters, and cheaters;” all of which, with many others, occur in his one letter. It is this which, while it makes the unskilful (the public) laugh, makes the judicious (the thinking part of the Profession) grieve. To my mind, the one word “delusion” is more applicable, and goes much further than all this abuse. Admit this as the basis and mainspring of Homeopathy, and our conduct in relation to it is very simple: we want no passion, no excitement, no abuse. I am, &c.

“JUSTA AUT NIHIL.”

P.S. I fear your correspondent is in the habit of taking a partial view of things. He must, if he pleases, understand “negotia” after the “justa” in my motto. Will he forgive my asking him to understand? Or, if he prefers it, “justa” may be translated—“due rate, proportion, or allowance.” I am sorry to deprive him of his point, but I cannot admit his exclusively feminine view of the word.

[To the Editor of the Medical Times and Gazette.]

SIR,—The Profession has already gained something in searching out the sources of the muddy Homeopathic streams, which are tainting the pure waters of Medicine. The high-placed Physicians and Surgeons, whoever they be (and fame says that their number is not few), who entertain professional relationship with the globulists, preserve an ominous silence. They are evidently not proud of their friends. They will meet the gentry, it seems, in consultation; they will, in the silence and the darkness of the sick man's room, pocket the *honorarium*—an honourable recompense, truly!—thrown in their way; but they do not care to acknowledge the dubious connexion in the face of the professional world. They desire that the whole transaction should be a *sub-rosa* one; and there is, we will suppose, still a blush of shame tingling on the cheek when the dishonest gains touch the hand. The fact that no one of them has yet come forward to publicly defend the practice which he indulges in and profits by, is, at all events, an acknowledgment of respect paid to the virtue of our Profession. The money is grateful to the touch; but the source from whence it is obtained is tacitly admitted to be of questionable respectability. But what will their Homeopathic patrons think of them? It is not pleasant to be cut dead in the morning before all your acquaintance by an aristocratic friend, into whose pocket a considerable number of your guineas found their way on the preceding evening!

But, Sir, you will not permit the wise silence of these men to be a stifling of the subject. You will not be contented with mere expressions of indignation—that the words should quietly pass away, and that the practices they describe should still run their course. I trust you will arouse, and have already aroused, the sense of honour in our Profession; and that the Profession, who has the power, will insist on having satisfaction from those who have injured its honour.

It has come to this, as I see the matter: either our Profession must be purged of the disgraceful dalliance with quackery, or it sinks to the level of the lowest trade. It sinks lower than a trade—it is converted into a downright imposture. Talk of quacks, and vile deceptions, and robberies of the public!—why! what quackery can exceed, what deception be viler, and what robbery greater, than the quackery, and the deception, and the robbery which are practised by the man who, professing to be a Physician,

stands by the bedside of his patient—his victim rather—and confers with an Homœopath concerning the treatment of the disease? We have honoured the martyrs who sealed their faith with their blood, and we have pitied those whose courage failed them in the trial; but I doubt whether history, excepting in the case of him who sold his birthright for a mess of pottage, has many tales like this to tell—where men, who stand before the world the illustrations of a noble Profession—who hold, as it were, its honour in their hands—have abjured their faith for a guinea.

I appeal to the common sense of men, whether there is any position more utterly degrading than that which the Physician holds when he stands in consultation with a Homœopath? He acts towards the patient the part of a swindler, for he sanctions, if only by his presence, a method of treatment which he knows to be a cheat. He is untrue to himself, for he must have stifled the prickings of conscience before he could have brought himself to this pass. He is false to his Profession, for he betrays the honour of it, which he once solemnly swore to uphold, and assists in dragging it in the mire. He does his best to elevate fraud and deceit in the treatment of disease, by caressing the vilest of quackeries. These words may be strong, but I solemnly declare that I believe the accusation they convey to be literally true; and I fervently trust, that no glitter of high professional position will prevent their application by the members of our body, to those who have rendered themselves amenable to the accusation.

They are wisely silent, these men. They well know that every attempted word of justification would be their condemnation, that every palliative argument they could suggest for their conduct would be a weapon for their conviction. Let us, however, cut the ground from under their feet, and explain away, by anticipation, every excuse which they might possibly offer for their conduct. Let us hear their excuses, and see if they gain exemption thereby from the serious charges imputed to them. I, says one, go merely to diagnose the disease; it is expressly understood that I have nothing to do with the treatment; the diagnosis given, I take my leave. Such a one, by his own admission, becomes in the hands of the Homœopath what the stethoscope is in his own—a mere tool. By his act he degrades himself and his Profession; and by his presence, he fosters and abets what he knows to be a vile deceit. Another may say, that the patient requires no prescription, that regulation of mode of living is his proper treatment, and that, therefore, these harmless globules may as well be administered as not, if the patient has an inclination for them. But this man, also, cruelly betrays his Profession. The globules are taken, a careful mode of living is pursued, the patient recovers; and to what does he, and the world, and the noisy, boasting quack ascribe the cure? Not assuredly to the rational mode of living, which in such case was the true medical treatment, but to the miraculous efficacy of the globule, to the infinitesimal dose. And the Physician's name serves to attest the truth of the quackery. What sort of a conscience must he have who can, in such a case, pocket his fee, and laugh at the credulity of mankind?
